PART II. STATISTICS.—Continued.

CHAP. IX.

Manufactures.—Continued.

Sect. III.—Manufactures of Silk, Linen, Stockings, Leather, Iron, Steel, Copper, Brass, Toys, &c.; Earthen and China Ware, Glass, Paper, Hats, &c.; Variety of Manufactures concentrated in single Towns, as in Bristol, &c.

Although the silk manufacture is of considerable antiquity in England, yet it has never flourished to any great extent; and at present is of very inconsiderable importance and value. It appears, that about the middle of the 13th century, a very large quantity of silk goods, (at that time a rarity in almost every part of Europe), was brought into this country. The novelty and splendour of this article of dress seems to have excited general interest among our nobility; but it was not till nearly two centuries afterwards, that the silk manufacture was introduced. Between the years 1455 and 1463, the women in many parts of England were engaged in it; and in order to encourage their labours, the importation of several articles of foreign silk was prohibited; this prohibition was reinforced under severe penalties, about 20 years afterwards; but it seems not to have been effectual, as foreign silk goods were not only much better, but much cheaper, than any that could be made here. About the beginning of the 17th century, the manufacture of broad silk was introduced; King James having previously in vain attempted to introduce silk worms into this country. In 1629, the silk-throwers in London were incorporated; and this branch of the trade seems to have flourished so well, that about 30 years afterwards their numbers in the metropolis amounted to 40,000. So far back as the year 1558, the Russian company had imported raw silk probably the produce of China, procured through Russia; but the quantity was very inconsiderable; and the silk trade was much impeded and cramped by the difficulty of procuring it from other places. This obstruction continued till the year 1681, when, in consequence of the importation of raw silk from India, it is stated that the English silk manufacture was quadrupled. Within four years after this, the French refugees came over, and were established in Spitalfields, and at Canterbury, and other places. From 1686 to 1688, the average annual importation of silk imported from France, amounted to upwards of £700,000. The year 1719 forms a remarkable epoch in the history of the silk trade in England; a patent having been granted at this time for the famous machine for throwing silk, erected by Sir Thomas Lombe and his brother, made from a model they had clandestinely obtained from Italy. By means of this machine, it was confidently expected that the manufacture of silk would be much extended, being no longer dependent on foreign countries for a supply of the prepared material. The silk manufacture was indeed extended, but it appears that the importation of Italian organized silk was indispensably necessary for the warp in the manufacture. An act of Parliament was therefore passed in the year 1779, to permit the importation of it in the most free and unrestricted manner; and this act was reinforced in 1783. The silk trade of this country may justly be deemed to have been at its acme about this period, since very shortly afterwards cotton, in a great measure, superseded silk for ladies' gowns. In 1783, an estimate (to which we have already referred) was published of the annual produce and condition of the principal manufactures in this kingdom; according to which, the silk manufacture was rated at £3,550,000; most probably an overcharged estimate. It is curious to observe the estimate which this author puts on the value of the cotton trade at this time—only £950,000. How
different are the two manufactures at present! So rapid and general was the change of fashion, which substituted cotton for silk, that in the year 1793, in the neighbourhood of Spittalfields alone, 4,500 looms were shut up; these looms, when in full work, gave employment to 10,000 people, of whom more than a half were women and children. A short time before this, the East India Company, in order to encourage the British manufacture of silk, introduced into Bengal the Italian method of winding it; and they were able to render this country in a great measure independent of Italy, &c. for raw and thrown silk; besides, it was ascertained, that the throw mills in England, on the whole, threw only about 50,000 pounds of silk in the year, which was not equal to an eighth part of the thrown silk imported. But, unfortunately, the revolution in fashion took place just about the time when the East India Company had matured their plans.

The following is the state of the silk manufacture of this country at present, in the principal places where it is carried on:—At Derby, there are 12 twist mills, on the model of those brought over by Sir Thomas Lombe, which give employment to about 1000 people, mostly women and children. At Macclesfield, between 20 and 30 silk mills are generally at work for the throwing of silk and making of sewing silk, most of which are turned by water; waste silk is also spun for the making of stockings and silk handkerchiefs, ribbons, tape, &c. manufactured. At Leek, ribbons, sewing silk, silk twist, and buttons: this place and Coventry have taken away a considerable part of the silk trade from Spittalfields, in consequence, it is supposed, of the effects of the act of Parliament for regulating wages at the latter place. Coventry and Atherton in the same county, are the principal places for the manufacture of ribbons. At St Albans and Watford, in Hertfordshire, there are silk mills on a new and improved construction, which give employment to a considerable number of people. There are likewise silk mills at Sheffield; Brutton, in Somersetshire; Sherbourne and Stalbridge in Dorsetshire; Nottingham, Chesterfield, Congleton, where silk is spun for the ribbon manufacture at Coventry, and several other places. Silk goods, of various descriptions, are manufactured at Oakingham and Colchester; silk handkerchiefs at Manchester, &c.; and at Towcaster in Northamptonshire, the chief manufacture is silk wrought by machinery. We have already mentioned, that part of the Spittalfields manufacturers have been transferred to Coventry and Leek, in consequence of the act for regulating wages; this act has also induced some master manufacturers of gauze, who used to make that article in Spittalfields, to remove their trade to Reading, in Berkshire, where it is rather in a flourishing state. Spittalfields, however, must still be regarded as the principal seat of the silk trade of this country: in that district, there are upwards of 20,000 looms employed, principally in the manufacture of light silks, which are exported to America when the trade is open. As there is less of the raw material in them, the English manufacturer can compete, in the American market, with the French manufacturer; and it is otherwise with heavy silks, in which the proportion of the raw material is greater. Besides America, the West Indies take off a considerable part of their goods; and it is calculated that one third are used for home consumption. The slight articles are made almost entirely by women and children. There are three persons to two looms, besides windsters and warpers; from this, and from the circumstance mentioned before, that when the trade was so laid in the year 1793, that 4500 looms were shut up, 10,000 people were thrown out of employ, we may safely reckon the total number of people employed in the silk manufacture in Spittalfields at between 25,000 and 30,000.

Mr Grellier has attempted to estimate the value of this manufacture in the following manner: "The average quantity of raw and thrown silk imported in three years preceding the 5th of January 1797, was 883,458 lb. the value of which when manufactured is about L2,700,000. The cost of silk to the manufacturer, if raw and thrown are taken together at only 2s. per pound, amounts to L1,260,000; and the profits of the manufacturer L245,454, at the rate of 10 per cent. on the cost when manufactured." He adds, that the number of persons employed in this manufacture has been stated at 200,000, but there appears no reason to believe that it exceeds 62,000 of all descriptions. This estimate seems to be manifestly wrong in one important particular. Mr Grellier takes the profit of the manufacturer at the rate of 10 per cent on the cost of the article when manufactured; but the value according to him is L2,700,000; ten per cent. on this is evidently L270,000, and not L245,454. The imports of silk from Italy in 20 years, from 1781 to 1801 inclusive, were on the average per annum about 4200 bales. The imports from 1800 to 1803 were rather greater, amounting to 672,400 pounds. The average annual imports of silk from Bengal, from 1775 to 1794, amounted to 3240 bales; and from 1795 to 1804, the average import from Bengal was about 2128 bales. From this it will appear, that the annual consumption of silk is about 6328 bales, or nearly 950,000 pounds. Assuming the price to be 30s. per pound, the value of the raw material will be L1,425,000; and supposing that the average increased value of all silk goods when manufactured is three times that of the raw material, the value of the whole silk manufactured will be L4,275,000; deducting from this the sum of L1,425,000, it will give us L2,850,000 as the sum out of which the interest of capital, manufacturing profit, and labourers wages are to be taken. If we reckon 20 per cent. on this sum for the two former, it will give 641,000; and the remainder, L2,609,000, will be the amount of the labourers wages. As a very large proportion of these live in London, we cannot reckon their wages on an average of town and country, and men, women, and children, at less than 15s. a week, or about L40 a year. If, therefore, we divide the sum of L2,609,000 by 40, we shall probably come near the number of people employed in this manufacture: this will give us 65,250, and this number of people seems much more probable than the number stated by Mr Grellier, when we consider that in Spittalfields there are about 25,000 or 30,000, and that in Coventry the ribbon trade occupies a considerable proportion of the inhabitants.

The linen manufacture of England is of very small importance, though formerly it appears to have manufactured goods of greater extent and value. This article was made in this country so early as the year 1189, but at that time by far the greatest quantity used, as well as that of the finest quality, was imported from Flanders. About the middle of the 16th century, Norfolk engaged in this manufacture, and a particular privilege was granted to this county, of manufacturing a kind then called Dormick in it. About a century afterwards, Irish linen yarn was much imported, and manufactured into linen in Manchester; and it is rather singular, that notwithstanding the almost overwhelming influ-
ENCE of the cotton trade, this manufacture still keeps its ground in Lancashire nearly to as great an extent as in any other district of England. Towards the end of the seventeenth century, our importations of linen from France were very large. Mr King, in his British Merchant, rates them at the annual value of £900,000; at the same time he gives rather a favourable view of the increase of this manufacture in England. In Lancashire and Cheshire alone, he says there was an increase to the amount of £240,000 per annum; and that in these counties there were 10,000 looms, and 60,000 people wholly employed and subsisted by that manufacture. The increase in Dorsetshire and Somersetshire (where this manufacture still subsists) he estimates at £100,000, and in the other English counties at £40,000. The importation of linen appears at this time (1702) to have been recent; for he reckons the whole amount of it £80,000 under the head of increase. Besides linen of our own manufacture, we procured it from Scotland to the amount of £100,000, from Holland to the amount of upwards of £200,000, and from Germany to the amount of upwards of half a million. The annual consumption of all linen he rates at £1,750,000, of which he says that the English manufacturer supplied £746,561, or 1d. Such, according to him, was the state of this manufacture in England at the beginning of the eighteenth century. Parliament seems to have been early anxious to encourage and extend this manufacture. By the act of tonnage and poundage, passed in the 12th of Charles II. duties were imposed on foreign linens; but in consequence of their not being duly proportioned and levied, and of the decrease in the value of the money duty, as well as the improvements in the fabric of German linens, they were not so beneficial as was expected and intended. In the year 1745, a bounty was granted on the exportation of British linens; and in 1715, this bounty was augmented. It appears by the custom-house books, that, prior to the year 1746, British linen was so small an article of export trade, that the whole quantity exported from England never amounted in any one year to 200,000 yards; and it may be remarked, as forming a striking contrast between the state of this manufacture in England and Scotland at that time and at this, that the whole export from the latter country did not reach 90,000 yards. The increase of the manufacture in England will appear from the following facts. In the year 1743, the year when the bounty took place, the quantity exported from England drawing bounty was 92,779 yards; in 1753, 641,510 yards; in 1763, 2,308,310 yards; in 1773, 5,608,238 yards; and in 1783, 8,667,915 yards. On an average of 10 years, from the 5th January 1776 to the 5th January 1786, the linen drawing bounty exported from England was 5,315,854 yards; and the total average quantity of what was exported and what was consumed in England in 1785 was 30,000,000 yards, a value nearly £1,500,000 per annum, and employing and supporting about 200,000 people. It ought also to be remarked, that the increase in the exportation of the finer linens not entitled to bounty, between 1748 and 1753, was nearly as great in value, though not in quantity.

Yet notwithstanding this increase in the linen manufacture of England, the importation of linen from Ireland continued to increase; and it is worthy of remark, that at this period, from a comparison of the English imports and exports of Irish linen, it appears that four-fifths; or perhaps seven-eighths of the whole, were consumed by the people of England, and those mostly of the finest quality. The Lords of Trade, in investigating this subject, reckoned the home consumption as at least four-fifths; but while the importation from Ireland increased, that from foreign countries diminished, as will appear from the following statement:

This manufacture, as well as that of silk, suffered from the rivalry of the cotton manufacture about the year 1790, but not nearly to so great a degree. There are very few data respecting this manufacture about this period. It appears, however, that the quantity of linens printed in England and Wales in the year 1796, was considerably less than the quantity printed in 1800, though the exact difference cannot be stated, as the returns laid before parliament did not distinguish between printed linens and stuffs. Besides the substitution of printed cottons for printed linens in dress, the latter trade must have suffered by the very general adoption of cotton stockings instead of thread ones, while the great increase in the importation of Irish linens must have discouraged another branch of the trade.

That the principal branch of the linen manufacture must at this time be at a low ebb in England, and appear from the following facts, ascertained from official documents: On an average from the union with Ireland to the 5th of January 1813, there have been annually retained, for home consumption in this country, 32,736,938 yards of Irish linen. The annual average quantity of plain linen imported from Germany, and retained for home consumption, between 1801 and 1812, was upwards of two million yards; from Russia nearly the same quantity; from Holland and France very trifling. Although not immediately connected with this part of the linen trade, we may add from the same documents, that, from 1801 to 1813, the annual average quantity of Hessen's canvass retained for home consumption, was upwards of 700,000 yards; of packing upwards of 300,000 yards; of damask and diaper of Silesia, between 60,000 and 70,000 yards; of cambric and French lawns upwards of 17,000 whole pieces. All the Silesia lawns were exported again. Of sail cloth, upwards of 47,000 ells were retained for home consumption; and of chequered and striped linen upwards of 12,000 ells. The average total of all sorts retained for home consumption during this period, was 14,539 pieces, 5,836,621 ells, and 64,706 yards. Although this statement includes Scotland, yet as little foreign linen (except Irish) is used there, it may be taken as a sufficiently accurate statement of the consumption of foreign articles made of flax and hemp in England; and in conjunction with the statement of the average quantity of Irish linen retained, it at least serves to prove, that the linen manufacture in England cannot be of much importance or value. It may, however, be proper to point out the principal places in this country, where articles are manufactured from flax or hemp.

Canevas for sailcloth is manufactured at Warrington, though not nearly to so great an extent as formerly, as at one time it was calculated that half of the heavy sailcloth used in the navy was manufactured here; at Kirkham, in the Filde district of Lancashire, where a large quantity is made for the navy, 6000 bolts of canvass having been supplied by two houses in the space of six months; at Lancaster, Whitehaven, Working-
England.

In Nottinghamshire, the stocking-trade is still more extensive, as well as valuable, than in Leicestershire. Besides stockings, stocking-pieces for pantaloons, &c. are made; and of stockings themselves a great proportion are silk. Thread stockings were formerly made here in great quantities, but, as before mentioned, since the advancement of the cotton trade, they have been entirely superseded by cotton stockings. The trade of Nottinghamshire has undergone great fluctuations, and is by no means at present in a settled state. In the year 1807, which was a flourishing year, it was very great in all its branches. Besides stockings and stocking-pieces, cotton caps have been made in this county for some years. These are exported in great quantities to the Mediterranean, 60,000 dozen having been sent in one year. Formerly the counties bordering on this sea, were supplied from Germany; but the manufacturers of Nottinghamshire gained possession of the market, by superior industry and attention, and smaller profits. Pieces are also made in the frame, which are afterwards cut up into gloves, and exported to the United States and Canada. All kinds of fleecy hosiery are likewise made; but what principally distinguishes Nottinghamshire, is its manufacture of lace on the stocking-frame. Warp lace was invented in 1804; and, in the year 1805, cotton-yarn (for this lace is made of cotton) was wrought fine enough to be made into double press lace, and so much approved, that in 1807 there were 1200 frames employed; and in 1808, 1500. About this time an inferior kind of lace was made; and it is said that the decaying and unsettled state of the Nottinghamshire manufacture is, in a great measure, owing to the bad quality of these goods. Within these few years, a patent has been obtained for net silk lace, for ladies' veils, &c. in the making of which a great many women are employed, chiefly at Castle Donnington and its neighbourhood, in Leicestershire, dependant on Nottingham. The hosiery manufacture of Derbyshire is chiefly confined to those parts of the county that border on Nottinghamshire, and to Eton, near Tideswell. The number of frames employed, including those on which silk and cotton stockings are wrought, has been calculated about 1350. In all these counties, a large proportion of the manufacturers are men of small capital. Large quantities of cotton gloves are made in Leicestershire and Nottinghamshire: woollen gloves are principally made in Wales and the north of England.

Knit stockings are now seldom made; though, in the more hilly or retired parts of England, especially in Richmondshire, in the North Riding of Yorkshire, in Cumberland, and in the isle of Purbeck, and at Winchester in Dorsetshire, considerable quantities are made.

Linen-lace, made by bobbins, is the chief employment of the women in the small towns of Buckinghamshire, Bedfordshire, Oxfordshire, Northamptonshire, and in some parts of Devonshire. It is supposed that more lace of this kind is made at Newport Pagnell, in the first mentioned county, than in all the rest of Stockton, Whitby, Hull, Retford in Nottinghamshire, Reading, Oxford, Bridport, and all the district between that and Beaminster in Dorsetshire, as well as in the adjoining part of Somersetshire. At Bridport, there is also an extensive manufacture of nets of all sorts, linen, and small cordage. At one period during the late war, the number of contractors for sailcloths for the navy were in England 25, each having 20 looms, and each loom producing two pieces of canvas in the week; but England was so little able to supply the demand, that by far the largest proportion was obtained from Scotland, where the sailcloth manufacture was increasing, while those in England were diminishing.

In Suffolk, a considerable quantity of hemp is grown, which is manufactured into strong and coarse linen, and also into sacking and cordage. The latter are made chiefly in the vicinity of Stowmarket. Linen for sheeting is made at Bromsgrove in Worcestershire; and sacking for hops, &c. is manufactured in Berkshire, where 4000 people are employed, principally at Abington, and in most of the hop counties. These, with some other linen manufactories in different parts of Westmorland, Lancashire, Dorsetshire, Durham, &c. of very considerable extent or importance, may be considered as the principal in England. Linen thread is made in considerable quantity, by the poor people in cottages, in the neighbourhood of Workington, and exchanged with trades people for goods. Mills for spinning flax were first invented at Darlington, where they are still used. At this place, there is also a manufacture of huckabacks, diapers, and sheeting. It will be evident from this account of them, that, with the exception of the sailcloth manufacture, the value of the goods made, and consequently the value of the raw material, and the amount of the manufacturer's profit, and the workmen's wages, must be very trifling; and as in time of peace this principal branch must necessarily fall off very much, there seems no necessity, even if there were data, to endeavour to ascertain these particulars. It may, however, just be mentioned, that, in the opinion of Mr Grellier, the linen trade of England amounts to about one million annually.

As stockings are made of worsted, silk, and cotton, we shall consider the manufacture of them in this place. The art of knitting stockings was introduced about the middle of the 16th century; and within 27 years after needles had been applied to this purpose, the steel frame was invented, or introduced by one Lee of Caverly, in Nottinghamshire. This county, and the adjoining counties of Derby and Leicester, still continue the seat of the stocking manufacture. The Frame-work Knitters Company were incorporated in 1604; but during the first century after the invention, few improvements were made in the frames, as in 1600 two men were employed to work one frame. Latterly, however, great improvements have taken place in this machine, and it has been applied to various purposes besides the making of stockings.

The species of stockings made at present in Leicestershire, Nottinghamshire, and Derbyshire, in some respects vary from one another. In the first mentioned county, the stockings are principally or wholly of worsted or of cotton; very few, if any, silk stockings being made in the county. The worsted and cotton for manufacturing them, is prepared either in the county, or in the neighbouring county of Warwick, particularly in Warwick itself, where one house is very extensively concerned in this trade. The articles made in Leicestershire are principally light, consisting of sandals, gloves, half stockings, &c. a great many of which were formerly exported to America. The chief places in the county where this trade is carried on, are Leicester, Hinckley, and Loughborough; but in all the principal villages through most part of Leicestershire, the inhabitants are more or less engaged in this trade. It is calculated, that there are employed about 20,000 people. In Hinckley alone, 3000 are generally employed. The whole hosiery annually made is estimated at the value of £1,500,000.

In Northumberland, the stocking-trade is still more extensive, as well as valuable, than in Leicestershire. Besides stockings, stocking-pieces for pantaloons, &c. are made; and of stockings themselves a great proportion are silk. Thread stockings were formerly made here in great quantities, but, as before mentioned, since the advancement of the cotton trade, they have been entirely superseded by cotton stockings. The trade of Northumberland has undergone great fluctuations, and is by no means at present in a settled state. In the year 1807, which was a flourishing year, it was very great in all its branches. Besides stockings and stocking-pieces, cotton caps have been made in this county for some years. These are exported in great quantities to the Mediterranean, 60,000 dozen having been sent in one year. Formerly the counties bordering on this sea, were supplied from Germany; but the manufacturers of Northumberland gained possession of the market, by superior industry and attention, and smaller profits. Pieces are also made in the frame, which are afterwards cut up into gloves, and exported to the United States and Canada. All kinds of fleecy hosiery are likewise made; but what principally distinguishes Northumberland, is its manufacture of lace on the stocking-frame. Warp lace was invented in 1804; and, in the year 1805, cotton-yarn (for this lace is made of cotton) was wrought fine enough to be made into double press lace, and so much approved, that in 1807 there were 1200 frames employed; and in 1808, 1500. About this time an inferior kind of lace was made; and it is said that the decaying and unsettled state of the Northumberland manufacture is, in a great measure, owing to the bad quality of these goods. Within these few years, a patent has been obtained for net silk lace, for ladies' veils, &c. in the making of which a great many women are employed, chiefly at Castle Donnington and its neighbourhood, in Leicestershire, dependant on Nottingham. The hosiery manufacture of Derbyshire is chiefly confined to those parts of the county that border on Northumberland, and to Eton, near Tideswell. The number of frames employed, including those on which silk and cotton stockings are wrought, has been calculated about 1350. In all these counties, a large proportion of the manufacturers are men of small capital. Large quantities of cotton gloves are made in Leicestershire and Northumberland; woollen gloves are principally made in Wales and the north of England.

Knit stockings are now seldom made; though, in the more hilly or retired parts of England, especially in Richmondshire, in the North Riding of Yorkshire, in Cumberland, and in the isle of Purbeck, and at Winchester in Dorsetshire, considerable quantities are made.

Linen-lace, made by bobbins, is the chief employment of the women in the small towns of Buckinghamshire, Bedfordshire, Oxfordshire, Northamptonshire, and in some parts of Devonshire. It is supposed that more lace of this kind is made at Newport Pagnell, in the first mentioned county, than in all the rest of
England. At Honiton, in Devonshire, the broadest lace is made; but, since the introduction of the Nottinghamshire cotton lace, that made of linen thread has fallen much into disuse; nor is the decline of the trade to be lamented, since, from the sedentary habits which were necessary to carry it on, and from the practice of the females who were engaged in it, crowding together in small, ill ventilated rooms, in the winter time, for the purpose of keeping themselves warm, it produced much ill health in the districts in which it was the chief occupation.

As somewhat connected with this subject, we may mention the manufacture of shirt-buttons. This trifling article is made to a considerable amount, in many towns in Dorsetshire, particularly about Blandford and Shaftesbury; and a practice prevails here, which we have already noticed as prevailing with respect to the making of linen thread at Workington. The shirt-buttons are generally exchanged for goods to the tradesmen, who, in their turn endeavour to force them off in exchange for what commodities they may want. This practice of paying for one species of manufacture by another, or rather of compelling the labouring manufacturer to take goods in exchange for his work, seems to have prevailed at an early period; since a law was passed against it in the time of Edward IV. and another law in the time of George II.; but the practice still prevails, as we have seen in Dorsetshire; and, when trade is bad in Nottinghamshire, it is reported to.

As the manufactures of wool, cotton, silk, and linen, may be regarded as intimately connected, both with respect to the mode in which they are for the most part carried on, and the purposes to which the goods they produce are applied, we shall subjoin to this account of them a curious and striking instance of the division of labour, as related to them, before we proceed to the other species of manufactures in this kingdom. In most places where woollen, cotton, or linen goods are made to any great extent, there are a set of men who are denominated fine-drawers: the business of these men is to examine the goods, and if they find any rent or blemish, to mend it in such a manner that it either may not be perceived, or at least may not injure the sale of the goods. But besides these fine-drawers, there are in London a set of men denominated packers. Men of the same denomination are found in all the large manufacturing towns; but a packer, in the London acceptance of the term, is almost, if not entirely, confined to the metropolis. His business consists in this:—When a merchant receives orders from abroad for superfine cloths, kerseymeres, &c., or cotton or linen goods, he applies to the packer, who, from his experience, knows exactly the kind of goods which are wanted, and where they are to be procured. The packer takes the orders to the factors, and purchases from them what he deems necessary and proper; but as many of these goods are sold in an unfinished state, undyed, and perhaps unsoured, the packer sends to the souring, dyeing, pressing, dressing, &c. Even after this, his labour and most peculiar business only commences: for he has to ornament and decorate them according to the market for which they are wanted; since, if goods were taken out to the East Indies, for example, without the appropriate ornaments, the natives would not believe that they were of British manufacture, and would consequently refuse to purchase them. The packer employs the fine-drawer under him, to examine if there be any flaws, and fine-draw them.

The leather trade of England is one of considerable extent and importance; but there are no materials which can supply even a sketch of its history. In the political essays concerning the British empire, published in the year 1772, by J. Campbell, (though without his name), he gives the following estimate of the value of this manufacture in Great Britain. Although it comprehends Scotland, and it does not appear on what data it is grounded, yet, as this author seems to be accurate and well informed on other points respecting the state of our manufactures at this period, we shall, in the absence of more satisfactory statements, subjoin it. Susposing that there are nine millions of people in Great Britain and Ireland, and that three-fourths of them wear leather shoes, (which cannot be beyond the reality), each person upon a medium five pairs in a year, and the price, on a medium, 6s. a pair, (boots included), this consumption amounts to L10,425,000. Supposing the consumption of leather by coaches, chaises, &c. - 100,000
By harness, saddles, and bridles - 500,000
By leather breeches, suppose 200,000 pair to be worn annually, at 10s. on an average

Total L11,725,000

The reader will not fail to remark the large sum allowed for leather breeches, an article now seldom met with among the lower classes, (with whom it was then very general,) and not very much worn by any rank. Of this calculation it may be remarked, that it estimates the population of Great Britain and Ireland too low, but probably it does not carry the value of the leather manufacture (if we suppose the calculation to apply only to Great Britain, and the population of it, independently of Ireland, to have been 9,000,000, much too high. In the year 1783, according to the estimate of the annual produce and condition of the principal manufactures in Great Britain at that time, already referred to, the annual produce of leather was stated at L10,500,000; and it was said to be in a declining state.

About two years ago, in consequence of an intention on the part of government to lay a tax upon leather, most of the principal people connected with the different branches of the trade were examined before a Committee of the House of Commons. The information on the state of this manufacture, connected with our subject, which they gave, we shall lay before our readers, along with information on other points on which they were not called upon to give their evidence. The first point relates to the supply of the raw material. This of course we get in large quantities at home; though the foreign hides are estimated at three-sevenths of the whole quantity used; and of the skins of calves, sheep, and deer, one half.

The importation of raw hides appears to have been most considerable from the continent of Europe, till the year 1807, when it fell off nearly one-half. In 1808 and 1809, it was not one-tenth of what it had been prior to 1807; in 1810 it rose higher than in any preceding year, (from 1803 except 1805; in 1811 and 1812, it again fell very low, not amounting on the average of these two years, to one-tenth of the importation of 1807. From 1803 to 1807, the importation of hides from America was next in amount to the importation from Eu-
Europe; but in 1808, the importation from America was tripled; and in 1811 it was again tripled. For some time after we began to trade with Buenos Ayres, hides were the principal remittance in return for the goods sent out. The importation of raw hides from Ireland and the West Indies has continued nearly stationary. With respect to the importation of tanned hides, skins, and leather, it takes place chiefly from Ireland, from the continent of Europe in time of peace, and sometimes from the East Indies.

According to the opinion of the leather manufacturers, examined before the Committee, the leather tanned within the limits of the chief office in London, bears about the proportion of one to eight of all the leather tanned in England and Wales. Proceeding on this supposition, we have, from the return of leather tanned within the limits of the chief office between the 5th January 1812 and 5th January 1813, calculated the quantity of all the leather tanned within that time in England and Wales, as follows.

<table>
<thead>
<tr>
<th>Item</th>
<th>Quantity</th>

<tr>
<td>Goat's skins tanned in do.</td>
<td>563,824 dozen.</td>
</tr>
<tr>
<td>Roans tanned in do.</td>
<td>273,820 do.</td>
</tr>
<tr>
<td>Pieces of goat and deer skins</td>
<td>396,830 weight 334,744</td>
</tr>
</tbody>
</table>

In almost every part of England and Wales there are tanneries; but they are most numerous and extensive in Cumberland, Westmoreland, Lancashire, Cheshire, particularly the middle part of the county, Shropshire, Sussex, Berkshire, (at Wantage in this county is one of the largest in the kingdom,) Lincolnsire, and Northumberland. About Louth, in Lincolnshire, large sheep skins, called Lincolnshire basins, are tanned, which are used for blacksmiths aprons. But by far the greatest tanneries are in Bermondsey, in the Borough. The manufacture of what is called Morocco leather is almost entirely confined to this place. The goat's skins used for this purpose are chiefly got from Mogadore, in Morocco; some also come from Germany, but they are of an inferior quality. The capital necessary for the tanning business is very considerable, since, besides what is laid out in buildings, &c. there must be sufficient to wait the returns, which are necessarily very slow. It is calculated that the capital employed, taking in buildings, pits, hides, bark, &c. is more than double the annual sale. The tanners complain that it requires a greater weight of hides to make a pound of leather now than formerly; and this they ascribe to the rapid manner in which cattle are fattened.

The principal leather manufacture, is, of course, that of shoes, either for home consumption, or for exportation; and the counties in which shoes are made, on the largest scale, are Northamptonshire and Staffordshire. In the former county, Northampton, and more particularly Wellingborough and Kettering; in Staffordshire, the county town and Newcastle-under-Lyne are the principal manufacturing places; in most of which, the leather is delivered out by the master manufacturers to the small makers. Shoes are also made at Nantwich, Congleton, and Sandbach in Cheshire, by the small makers, and sent to the London ware-houses. While the war lasted, the demand for shoes for the army was very great; the contractor generally supplying upwards of 600,000 pair annually; these he procured almost entirely from Northamptonshire and Staffordshire. In Stafford there was one house which employed 1000 workmen, and made about L75,000 worth in the course of the year. In this manufacture, a considerable number of women and children were employed; and it may be remarked, that during the war a number of people in Norwich and other places found employment by sewing soles to the list shoes made by the French prisoners. Leather slippers are made in great quantities at Bicester in Oxfordshire.

It is impossible to conjecture the probable quantity of leather used in various ways for home consumption in this country: perhaps the following facts may throw some light on this subject. The probable annual consumption of leather for one pair of a gentleman's coach harness, is about 10 pounds; for a common riding saddle and bridle, about 5 lbs.; for cart harness, about the same quantity; for boots, 16 lbs.; for walking shoes, 7 lbs.; for dress shoes, 8 lbs.; for high-faced shoes, 7 lbs.; and for soldiers shoes, 6 lbs.

Shoes are principally exported to the East Indies, Batavia, the West Indies, and Canada; while we traded with the United States, a great quantity of women's shoes were sent thither, and many females were employed in binding them. Saddles are made in almost every town, but Sherborne and Lyn are particularly remarkable for this manufacture: they are made here, as well as in London, for exportation. The hog-skins which, when tanned, are used for the seat of the saddle, are principally imported from Russia. We shall afterwards have occasion to notice this manufacture, when we come to treat of the manufactures in the hardware line about Birmingham.

Gloves are manufactured chiefly at Woodstock, Worcester, where the manufacture is so extensive that it employs nearly 500 women, besides men, and the returns are about L100,000; Stourbridge, Hereford, York, Swindon in Wiltshire, Yeovil in Somersetshire, Exham, &c. a number of weakly people and children are employed in this trade; but they are now made by machinery in some places. Chamois leather is dressed by mills at Darlington.

The amount of the value of this manufacture, in all its branches, is impossible to ascertain with any degree of accuracy, though it must be very considerable. In the article of shoes alone, the home consumption must be great; if we suppose that it costs each individual only 10s. a year, on an average of all classes and ages, and of both sexes, for shoes, this will bring the amount to above L5,000,000. The value of all other articles made of leather, such as harness, saddlery, &c. and what is consumed in coaches, must, at least, reach the same sum; so that, on a moderate calculation, the annual value of this manufacture may be rated at L10,000,000; estimating the value of the raw material at the usual rate, that is, as equal to one third of the value of the manufactured article, this will give us L3,333,333, leaving L6,666,667. As in many branches of this manufacture, especially in the most extensive, the shoe trade, there is little outlay of capital, except for the purchase of the raw material, probably 15 per cent. on this sum of L6,666,667 will be nearly the amount of manufacturing profit; this will be nearly L1,000,000, and the remainder, divided by L25, (the probable average amount of the annual wages of the persons who work at this manufacture,) will give us about 42,700 as the number of persons employed in the leather manufacture.

In treating of the mines of England, we incidentally noticed some of the iron works in which that metal was brought into the state of what is called pig and bar.
iron, partly because this process could scarcely be called a manufacture, and partly because we wished to form an estimate of the probable produce of the English mines, by ascertaining the quantity of pig and bar iron that was made in the kingdom. But now that we are about to enter on a view of the hardware manufacture, which, in point of extent and importance, is probably next to the wooden and cotton manufactures, and certainly has contributed, along with them, to raise the national character in the estimation of foreigners, very high, on the score of ingenuity and industry; it will be proper to commence this branch of our subject, by a notice of the most important iron founders.

Perhaps the most extensive are those at Colebrook Dale, in Shropshire, and at Mossbrough, near Rotherham, in Yorkshire, in which iron in all its forms is manufactured, from the ponderous iron bridge to small culinary utensils. At Burslem, near Wrexham, there are not only smelting furnaces, but furnaces for smelting the pig iron, and casting it into various articles, such as cylinders for fire-engines, water pipes, boilers, pots and pans of all sizes, box and flat irons, and cannon and ball of all dimensions. Here also are forges for malleable iron, and wire works, as well as a brass foundry. At Walton, near Chesterfield, there is a furnance and foundry, in which nearly the same articles are manufactured as at the works near Wrexham. There are likewise large iron founders at Bradford, Burton on Trent, Nestth, Merthyr Tydvil, Swansea, Tavistock, and many other places, particularly in the counties of Lancashire, on the northern part near Ulverstone, Durham, particularly at Swalwin, Wilmoton, Lumley, Shortis Bridge, Derwent Coat, and Blackhall Mills; at the three latter places are manufactories of steel for sword blades.—Gateshead, Chester-le-Street, and Sunderland; Yorkshire, Staffordshire, Shropshire, Derbyshire, and Monmouth. Copper works are established at Swansea, Aberavon, Cobham, (at these two places there are also iron works, indeed they are often united,) Wandsnorth, St Helen's, (at which place a very extensive business was carried on, while the Anglesea mines were most productive) likewise in the district of Furness in Lancashire. Great Marlow, where brass and steel thimbles are made. Holywell, where copper sheets for the bottoms of ships, copper-nails, bolts, brass, brass-wire and plate brass, are manufactured. Macclesfield, where also copper for sheathing ships is made, and a considerable quantity of brass, brass-wire, brass nails, &c.

But though these and other works of the like nature, especially some of the iron-works, may astonish us by their magnitude, yet, on reflection, they probably will not excite such wonder and admiration, as the manufactures of Birmingham and Sheffield, and the respective neighbourhoods of these towns.

Although many of the manufactures carried on in Birmingham come under the description of hardware, yet there are also many which cannot be classed under that or any other general head; but perhaps by no means can we give such an adequate idea of the manufactures of this place, as by the following enumeration of them, in which we will see their curious, minute, and almost endless variety. It is proper to remark, that, in general, each is a separate trade: this circumstance will account, in a great measure, for the exquisite workmanship of many of the Birmingham goods, and the low price of them all. After this enumeration, we shall offer some remarks on particular branches; for to detail particulars, even respecting a few of them, would carry us far beyond our limits.

Files, guns, pocket-books, gilt toys and jewellery, are manufactured there.
their acquaintance with some, probably with many, of the articles of Birmingham manufacture; their superior quality and cheapness must have been noticed, as well as their wonderful adaptation to the purposes of almost every art, that the necessities, or comforts, or luxuries of life requires, as well as to the demands of philosophy and science, and the most elegant curiosities of fashion; but perhaps few know that the articles with which they are acquainted, and which they admire, are the most valued in the whole of the town. We have remarkt noticing the town, or even the imagination, might be taxed, without being able to recall, or to conjecture, nearly all the articles which the workmen of Birmingham produce. Woollen and cotton goods are found over most of the continent of Europe; they contribute to the health or the comforts of the inhabitants of America, Asia, and Africa; but the demand for most of them so evidently proceeds from their being articles of necessity, of the best quality, and at the cheapest price, that we are not much surprised at their wide dispersion; but it is very different with many of the articles of Birmingham manufacture, which are mere toys, constructed indeed with the utmost skill and untired industry; but still mere toys; and yet they are more generally dispersed than any other of our manufactures; so that perhaps it would be impossible to go amongst the most remote, uninformed, and incurious nations of savages, that had ever been visited by Europeans, without discovering some proof of the workmanship of Birmingham.

But we should still form an inadequate idea of this place, and consequently of the state of the manufactures of England, (for when they are the subject, to omit, or partially to notice Birmingham, would be to do great injustice to it,) if we permitted the reader to suppose, from our silence, that all the manufactures carried on here are of the minute kind, which the list that we have given might lead him to suppose. Our object in giving that list, as we have already remarked, was principally to exhibit a picture of the curious, minute, and almost endless variety of the articles which this place produced. But, besides these, all the more ponderous productions of the casting furnace and rolling mill are here seen on the largest scale, and of the most perfect workmanship. We need only mention Messrs. Bolton and Watts manufacturing at Soho, in which the most stupendous steam engines that ever lent their aid to the labour of man, as well as an infinite variety of toys, in every species of metal and composition, are made.

The capital employed in the manufactures of Birmingham, is not very large. There are, indeed, in its immediate neighbourhood, ten sets of iron works, which are supposed to have cost L. 50,000 each; but in the town itself, most of the manufacturers are unincorporated small capital; some not possessing more than L. 400 or 500; and many not more than L. 2000 or L. 5000, employing from five to thirty hands. The whole amount of capital in Birmingham, (exclusive of the very large works,) is supposed not to exceed half a million.

The work is partly carried on in work-shops, and partly in the houses of the workmen. Women are principally employed in polishing the goods, in the glass-toy branch, and in making of braces. Boys are chiefly employed by the out-workers as apprentices, and receive the first year about one shilling a week, and the last year from five to ten, besides their clothing: but they receive their food at home. The wages of the men varies very much, both as to the particular branches in which they are engaged, and according to the state of trade. In some branches, where very superior skill, and great experience and attention, are requisite, perhaps as great wages are got, as can be obtained by any workmen in London.

It is impossible to state the number of men engaged, Number of even in the most considerable of the Birmingham manufactures, or the exact value of the articles manufactured. The population of the town itself, and of the manufacturing district, which extends about 15 miles, is estimated at 400,000; and it is supposed that nearly 100,000 are employed in the production of coal and minerals, and in the rough preparation of iron, for the manufactures of Birmingham. In the brass foundry branch, which is almost confined to the town, about 10,000 men are employed. In the button trade, from 7000 to 10,000. In the making of brass, a manufacture but lately introduced, about 1000. In the jewellery and gilding trade, from 6000 to 7000. In the making of many of the toys, a very small capital is employed, the value of the article consisting almost entirely in the labour employed in manufacturing it; thus a watch-key, which, perhaps, goes through twenty hands, will, after all, sell for 1d. or 14d. Perhaps the greatest number of hands are engaged in the burnishing line, it being supposed that nearly 20,000 are thus employed. The article of plated saddlery, which is the principal plated article not made generally at Sheffield, as well as at Birmingham, employs a considerable number of persons. Nor must the manufacture of muskets be forgotten, though that now, it is to be hoped, will be almost at an end. In time of war, muskets of the value of L. 400,000 were manufactured in Birmingham. Some years ago, when the trade with America was open, between 200 and 300 tons of steel were annually sent thither from this place. The total value of all the articles made in the town itself, is estimated at L. 2,000,000, of which one half is sold for home consumption. By far the greatest proportion of the other half was sent to the United States, when the commercial intercourse was open, and the remainder to South America, Spain, Portugal, Malta, &c.

Hitherto we have chiefly confined our notices to the manufactures of Birmingham itself; but the neighbourhood, including several populous towns, also demands our attention: some of these towns participate in the manufactures of Birmingham; others carry on manufactures little if at all followed in Birmingham. Pontypool, in Monmouthshire, was formerly famous for its manufacture of Japanese ware; but it is now continued there only on a very small scale, by the descendants of the family that first established it. At Birmingham, Bilston, and Wolverhampton, however, there is carried on with great spirit and success, and to a considerable extent. Wolverhampton also very largely partakes with Birmingham in the manufacture of screws; but it is particularly noted for the skilfulness of its locksmiths in constructing locks, which are exceedingly curious; some of them partaking of the nature of clock work, and being of very minute size. A great part of the ironmongery is made by the farmers of the adjacent country, (who, as well as the females, are regularly brought up to the business,) and sold by them to the great manufacturers. Saddlers iron-mongers are a class of manufacturers, some of whom are found in Birmingham, but who chiefly reside in Wolverhampton and Walsall; they cut out bridles and stirrups, and also manufacture and fasten on the iron work belonging to them. But the most extensive, as well as the most curious branch of the hardware manufacture, carried on in the vicinity of Birmingham, is the nail trade. Very
few nails are made in the town itself; but in Dudley, West Bromwich, and Stourbridge, and in all the country round these places, the making of nails is the chief employment. It is supposed that in the nailery district, at least 30,000 people are employed. This manufacture is almost entirely carried on in the houses and cottages of the labourers. Men, women, and children all work at it, and the display of forges at the doors of the houses is very striking. All the work is done by the piece,—bundles of iron being delivered to the workpeople, out of which they are expected to make a certain quantity of nails. In no trade, perhaps, do the labourers work so hard as in this. With their utmost efforts, from early in the morning till late at night, a man can seldom earn more than twelve or fourteen shillings a week. Nails used to be exported to the United States, None are sent to the Continent. This trade, which formerly used to be very extensively diffused over most parts of England, is now almost entirely confined to the neighbourhood of Birmingham. There are, however, manufactures of them at Little Dean, in Gloucestershire, Halesowen in Shropshire, and some other places. They were also made at Chowbent, in Lancashire, till the cotton trade superseded them.

The period at which manufactures were established at Birmingham, is comparatively recent; but Sheffield has been the staple for iron manufactures since the year 1297, at which time falcon-heads, arrow-piles, and an ordinary sort of knives called whittles, mentioned by Chaucer, and still known by that name in the north of England, were made. But it was not till towards the middle of the 17th century, that the articles of razors, knives, and files, for which it is at present so deservedly famous, were manufactured. It has been remarked, that for near a century succeeding, the Sheffield manufacturers discovered more industry than ingenuity or enterprise; and it was not till the middle of the last century, that they opened an immediate trade with the continent. About this time also, buttons of plated metal, sauce-pans, tea-urns, and candlesticks, were first made. Since this period, the manufactures of Sheffield have been progressively advancing.

The hardware manufacture is not confined to the town of Sheffield, but is spread over a district called Hallamshire, which extends six or seven miles to the west of it. The manufacturing concerns are under the superintendence and management of a corporation, styled the Company of Cutlers of Hallamshire. This corporation was established in 1625, and an amendment was made to it in 1791. It is governed by a master, two wardens, six searchers, and twenty-four assistants. The master is elected annually, on the last Thursday in August, having previously passed through the inferior offices.

In the neighbourhood of the town, a great number of works are erected on the river Don, for forging, slitting, and preparing the iron and steel for the manufactories. These differ in several respects from the manufactures of Birmingham. In the first place, copper and brass, as well as iron and steel, are wrought in the latter place; whereas, at Sheffield, very little of the former metals are used. Secondly, the articles made at Sheffield are more generally articles of real utility; some undoubtedly are articles of luxury, but there are no toys. Lastly, its articles, in general, are much larger than those of Birmingham. The following list of the principal trades in Sheffield, if compared with the list we gave of the trades of Birmingham, will point out in what they agree, and in what they differ: Knives, scissors, anvils, silver and plated goods, skates, joiners tools, saws, fenders, fire-irons, horn-buttons, horn ink-stands, bit-maker, razor straps, files, stovel-grates, candlesticks, steel-refiners, wool-shears, haft-presser, silver-smiths, braziers, and tin-smiths to make nails, spikes, scythes, and sledges, table-fork-blades, snuffers, cork-screws, nut-crackers, steel cats and dogs, lancets, desk-knives, tea-pot handle and knob manufacturer, buttons, coach-harness, weighing machines, brass ink-pots, powder flasks, shot bolts, bayonets, wafer-seals, saw-files, shoe, cooks, and butchers knives, combs, &c. &c.

The plated ware made at Sheffield, (with the exception of plated saddlery,) is deemed much superior to that made at Birmingham: their files also have long been in the highest repute; of the scythes and sickles, which form an extensive branch, the coarsest are sent to Russia; and a finer sort were exported to America. The conversion of iron into steel, forms a very considerable branch of the manufactures of this town; and the mechanics who are expert at this process, receive as large wages as any that are given. Great part of the manufactures are carried on by men of small capital; and not so generally in workshops or factories as is the case in Birmingham.

The population of Sheffield, and the manufacturing district round it, is estimated at 60,000; and it is computed that 18,000 are directly employed in the different branches: the proportion of men to women is nearly as two to one. The gross value of the manufactures is supposed to be upwards of L1,000,000, probably L1,200,000; of these about one half are for home consumption; one third used to be exported to America, of these, knives, forks, and saws, formed a large proportion; and the remainder were principally exported to the continent. Prior to the introduction of machinery, this place was observed to abound in cripples, but it is by no means the case at present.

Files have been mentioned as an article, in the manufacture of which Sheffield excels; they are also made of a superior quality, and in great numbers, in Lancashire, particularly at Prescot: cutlery and steel goods are manufactured at Salisbury. Cirencester is noted for its curriers knives, which are highly valued throughout Europe and America. At Abberford in Yorkshire, formerly the seat of an extensive pin manufactory, the wire-drawing business is now carried on with considerable success; this trade is also followed at various other places. Pins are manufactured at Gloucester, Reading, Sheffield, Warrington, Waltham Abbey, Bristol, London, &c. Needles at Redditch and Feckenham in Worcestershire, Alcester in Warwickshire, &c. Fish-hooks at Carlisle. Iron hoops at Crayford in Kent, &c. Tin-plates at Caerleon, Caernarveth, and Kidwelly; the last place is particularly noted for this manufacture, the tinned iron plates which are made there, being sent not only to every part of the kingdom, but to every trading port in Europe.

The average amount of the real value of the different Value articles, made of iron and steel, annually exported, is between L3,000,000 and L4,000,000; the value of articles manufactured of copper and brass exported, seems rather to be on the decline; in the years 1799 and 1800, the official value was between L300,000 and L900,000; whereas for three or four years past, it has varied between L200,000 and L300,000. The value of all the articles made of iron may safely be rated at L10,000,000; and the number of persons employed at 200,000. The
value of all the articles made of brass and copper is
about L.3,000,000; and probably the number of per-
sons employed about 50,000; and the value of the steel
plating and hardware manufactures, including the toy
trade, cannot be estimated at less than L.4,000,000;
the number of persons employed being at least 70,000.

Thus the total amount of the value of all these branches
of manufacture from different metals, carried on in
England and Wales, may be estimated at L.17,000,000;
and the number of persons employed at 320,000.

Under this head may be classed the manufacture
of watch-tools and watch-movements, which is carried on to a
considerable extent, and with great ingenuity and skill,
at Prescot, in Lancashire, and its neighbourhood. This
place has already been mentioned for the excellence of
its files. They are entirely of the smallest size; and
it is supposed that the celebrity of this place for
watch-movements, is principally owing to the superior
quality of their files and tools. The drawing of pinion-
wire had its origin at Prescot; and the manufacture of
watch tools has been carried on beyond the memory of
the oldest watch-makers. The workmen likewise ex-
cel in what is called motion-working, such as dial-
wheels, locking-springs; hour, minute, and second hands.
Main springs, chains for movements, and watch-cases,
were not part of the original manufacture, but are now
made here. All the branches of this curious and inge-
nious trade are, however, gradually removing to Liver-
pool, in the same manner as the fisture trade, which
originated in Bolton, has centered in Manchester. The
tool and watch-movement makers occupy small farms
in conjunction with their manufacturing business; in
this circumstance they resemble the weavers about
Manchester. A manufactory of watch-spring chains
has been established, within these few years, at Christ-
curch in Hampshire, in which many children are em-
ployed.

English earthenware forms a branch of its manu-
factures of considerable importance. It is made with
the greatest taste, and in the greatest variety, at the
potteries in Staffordshire. The towns and villages that
are so denominated, extend about seven miles, com-
encing about a mile from the borders of Cheshire,
and terminating at a place called Lane-end. Of these
villages, Burslem and Etruria are the most remarkable:
The first is the ancient seat of the manufacture, earthen-
wares of one kind and another having been made there
for centuries. Etruria belongs solely to Mr Wedge-
wood, whose father gave to the Staffordshire ware all
the celebrity that it has so deservedly and universally
acquired. Besides earthen-ware, china-ware is also ma-
ufactured in the pottery district.

The clay for this manufacture is brought principally
from the isle of Purbeck in Dorsetshire, and from Dor-
vonshire; the flint from Greenhithe in Kent, where
several thousand tons are shipped annually; these, and
other raw materials, are also brought from Cornwall,
Hampshire, Sussex, and Wales. It is computed that
nearly 40,000 tons of shipping are annually employed
in bringing these materials to Liverpool. When the
American trade was open, about 30,000 tons were em-
ployed in exporting the manufactured articles to the
United States; and nearly as many tons in carrying
them coastwise, besides what is sent by the canals.
The number of packages exported from Liverpool, be-
tween 1803 and 1811, varied from 25,000 to 47,000.

The population of the pottery district is from 38,000
to 40,000, of which about 15,000 or 20,000 are em-
ployed in this manufacture. Women and children are
employed, as well as men; and a family of three or
four children will, with their father and mother, in
good times, earn from 40s. to 45s. a week. They live
in cottages of from L.5 to L.8 annual rent; and, in gen-
eral, are healthy, industrious, and well-behaved. It
is customary to hire them from Martinmas to Martin-
mas, allowing them a fortnight's holidays in winter;
and of course, when the frost is very severe, they cannot
follow their work.

Earthen-ware is made in various other parts of Eng-
land; and china-ware, of a very superior quality, at
Worcester, Derby, and Colebrookdale.

In consequence of the great improvements that have
been made in this manufacture, and the introduction
of many new and beautiful wares, both for our own
use and foreign markets, the annual value of the whole
will probably not be over-rated at L.9,000,000; nor
the number of persons employed at between 35,000
and 40,000.

The manufacture of glass is of very early date in Glas-
na country, having been introduced, it is said, about
the end of the 7th century; but it was not till 900
years afterwards, that the manufacture of fine glass
was begun in London. About the beginning of the
17th century, a patent for making glass with pit coal
was exempted from the operation of the law against
monopolies. The importance of this manufacture now
becoming apparent in the year 1670, manufacturers
were procured from Venice; and within 15 years af-
wards, the French refugees, to whom we are in-
debted for so many improvements in our manufactures,
contributed to the improvement of this, especially in
the crystal branch of it. From the beginning till the
middle of the 18th century, we exported large quanti-
ties of glass bottles to Holland; but at the latter pe-
riod, in consequence of the erection of a number of
glass-houses in the United Provinces, this trade de-
clined.

The year 1773 forms an important era in the history
of the English glass manufacture. It was in this year
that the British Plate-glass Manufactory, incorporated
by act of parliament, erected their extensive works at
Ravenhead, near St Helen's, in Lancashire. Their
buildings cost nearly L.40,000. The manufactory was
introduced by workmen from France, from which coun-
try we had previously imported our plate-glass. The
article made at Ravenhead, soon rivalled the French
glass in its perfection and brilliancy of colour, as well
as in the size of the plates. In the year 1789, a steam-
engine was erected, to grind and polish the plates of
glass, which not only saved a great deal of labour, per-
forming as much work as would employ 160 men, but
did it with more exactness and expedition. Cast plate-
glass, with concave and convex mirrors, are now made
superior to any imported from the Continent. The
works cover about 20 acres of ground; and nearly 300
persons are usually employed in the various processes
of melting, casting, blowing, polishing, &c. Plate-glass
is also made now in London and Liverpool, the Plate-
Glass Company having been incorporated only for 21
years.

Manufactories of glass of all the other kinds are nu-
merous in this country. Bottle-glass is made at Bristol,
as well as crown and flint-glass. In Newcastle,
Sunderland, and Hartley-pans, there are a great many
houses for making crown, common window glass, flint
glass, and green bottles. Stourbridge, Warrington,
and several other places, have also their manufactures
of glass of various kinds. Near Darlington, there is a
mill for grinding optical glasses. This manufacture is so scattered, that it is difficult to form an estimate of its annual value, or of the number of hands employed in it. The former, however, may amount to upwards of L1,000,000; and the latter to between 30,000 and 40,000.

Paper. Paper, which is now made in such perfection in England, and to such a large annual amount, was almost entirely imported from the Continent, especially from France, till near the end of the 17th century. In 1685, this manufacture was much improved by the French refugees; yet we are informed by King, in the British Merchant, that before the revolution, there was hardly any paper made here, except brown. In 1690, white paper was first made; and, in 1695, all the kinds, white, blue, and brown, were much improved. In 1721, according to King, there were 120 vats within 60 miles of London, besides several more in Yorkshire, which all made white paper. These, together with some paper mills in Scotland, are said to have made more than 300,000 reams, which, at that time, was two-thirds of the whole consumption. Mr King mentions, that, in England, with five men to each vat, they did not dispatch above eight reams in a day; whereas, in France, with the same number to a vat, they dispatched above nine reams. At this time (1721) paper was valued at 6s. a ream. In 1763, the annual value of the paper manufactured in the kingdom was estimated at L7,800,000; and it was said to be increasing. At present, besides making sufficient of almost every kind for our own use, we export it to a considerable amount. The annual value of the article is probably rather more than L1,000,000, and the number of persons employed about 30,000. There are paper mills on almost every stream, the water of which is sufficiently pure for the purpose; but perhaps they are most numerous and extensive in the vicinity of the metropolis, particularly in Kent, near Maidstone; in Hertfordshire, Surrey, Buckinghamshire, Bedfordshire, Hampshire, &c. At Freefolk, in this last county, the paper for the Bank of England notes has been manufactured ever since the reign of George I.

Hat-making is a very considerable branch of English manufacture, which is now brought to great perfection. It seems to have been improved, like the manufacture of paper, &c. by the French refugees. It is carried on in various parts of the kingdom. At Newcastle-under-Lyme, coarse or felt hats are made, under an incorporated company of felt-makers. Immense quantities of these hats are exported to the West Indies, for the use of the negroes. Felt-hats are also made at Rudgley, &c.; and other kinds of hats at Stockport, Oldham, Manchester, Ashby de la Zouch, Burton, Atherstone, Cockermouth, Hereford, Hexham, Newcastle-on-Tyne, &c. But, in point of quality, no hats are equal to those manufactured in London. Straw hats are principally made at Dunstable.

The other manufactures of England we can only name; and probably from their great variety, our enumeration will not be complete. Gun-powder is made at Battle, Dartford, Hounslow, Waltham Abbey, Faversham, &c. Gun-flints are a manufacture almost peculiar to England. Shot is cast at Chester, the Borough, &c. Copperas works are established in the counties of Durham and Northumberland, in the Isle of Shepey, in Kent, &c. Aquafortis is made at Bradford in Yorkshire. Sal-ammoniac at Newcastle, Leeds, and a few other places. White-lead extensively at Newcastle; and white and red-lead at Chester. There are snuff-mills at Chester, Bristol, Liverpool, and Gloucester. Sugar refineries at London, Bristol, Liverpool, and Newcastle. Soap manufactories are established in many parts of the country; but London, Bristol, Newcastle, and Hull have them, perhaps, on a more extensive scale than other places. There are also manufactories of turpentine, linseed, rape, and other oils. The preparation of horse hair, furs, and feathers, employ a good many people. Brick-making is extensively carried on in the vicinity of London, and near those towns where stone is scarce and dear. But it would be endless, we perceive, even to attempt an enumeration of all the various kinds of manufactures of England. We shall, therefore, conclude this branch of our subject, by mentioning those manufactures, which are either confined to London, or carried on there to the greatest extent, and in the highest perfection; and with enumerating the great variety of manufactures that are concentrated in some of our large provincial towns, since the concentration of such a variety is perhaps little less astonishing, than the extent and magnitude of the whole through the kingdom at large. By thus concluding this part of our subject, we shall also have an opportunity of mentioning some kinds of manufactures which we may have overlooked.

The manufactures of London consist chiefly of fine goods, and articles of elegant use, brought to more than the ordinary degree of perfection; such as cutlery, jewellery, articles of gold and silver, japan ware, cut glass, (drinking glasses, cut in London, have been sold so high as three guineas per glass,) cabinet and upholstery work, and gentlemen’s carriages. The amount of capital, and number of men employed in the manufacture of these two articles, are not less surprising, than the elegance of taste and high perfection which are displayed in the articles themselves; both of which, especially carriages, are exported to a great amount. It is believed that the trade of a coach-carrier is carried on nowhere but in London. That of a gold-beater, also, is either exclusively confined to the metropolis, or seldom seen elsewhere. Clocks and watches, particularly the latter, are a very considerable article of manufacture; the parish of Clerkenwell containing, it is said, upwards of 7000 watch-makers. The value of the watches and marine chronometers made in London and its neighbourhood, is above £1,000,000, independent of clocks; the manufacturers of the making watches, not only for all the British dominions, but also for all the civilised world. London is likewise celebrated for the exquisite skill in the construction of its optical and other philosophical instruments. Besides these kinds of manufactures, and others which have been incidentally mentioned before, such as hats, &c. porter breweries, vinegar works, copperas works, calico-printing, distilleries, glue manufactories, iron foundries, oil mills, saltpetre works, vitriol works, turpentine manufactories, manufactures of whitening, dye-houses, &c. may be mentioned. Muffs, an article of no inconsiderable importance, considering the price which some of them cost, are principally manufactured in London; here also are chiefly found feather-dressers.

Varying in number, and perhaps in no provincial town, is there a greater variety of manufactures than in Bristol. Some of them have been already mentioned; but we shall enumerate them all, in order that an adequate idea may be formed on this subject. Varnishes of uncommon beauty are made here; hats; leather, both tanned and dressed in oil; saddlery, shoes, white and red lead, gunpowder, hard white soap of the best quality in great abundance,
ENGLAND.

In Newcas-
tle.

Newcastle-on-Tyne probably is next to Bristol in the variety of its manufactures. In this town, or its immediate neighbourhood, are iron furnaces; wrought iron works, in some of which anchor and various articles of naval ironmongery for the dock-yards are made; works for melting lead, refiners of lead, lead manufactories for rolling sheet lead, and converting pig-lead into cerce and minium for pigments; patent shot, colour manufactories, a manufacture of Prussian blue, glass works, potteries, manufactories of coal tar and lamp black, copperas manufactories, manufactories of sal-ammoniac, glauber's salts, soda, brown paper mills, soaperies, sugar-refineries, salt works, and a manufactary for spinning linen yarn.

In Hull.

At Hull, there are manufactures of sail-cloth, sugar-houses, soap works, oil-mills, iron foundries, lead manufactories, a manufacture (if it can be so called) where mill-stones are formed of the French bur-stone, several whale-oil yards, large breweries, saw-mills, flour mills, &c.

In Liverpool.

In Liverpool and its vicinity are salt refineries, sugar-houses, a vast number of manufactories for tobacco-pipes and pottery, iron foundries, breweries, a steam-engine for cutting and flattening iron, vitriol and whitelead works, mills for cutting dye-woods, smul-mills, salt and cooperas works.

Concluding remarks.

Thus have we endeavoured to give as accurate and complete an account of the nature and state of the various manufactures of England, as our information and our limits would permit. We are sensible it must necessarily be imperfect or erroneous in some particulars; but we trust in none of considerable importance. As an apology for at least some of the omissions or errors with which we may be chargeable, we must, in justice to ourselves, remind our readers, that several of the most extensive and valuable of the manufactures of this country have been for several years past in such a state of fluctuation, from the extraordinary character and effects of the war, out of which we have just rescued ourselves, that it is almost impossible to give such an account of them, as will at once apply to their present state, and serve for a general description. We have therefore preferred, in many instances, describing them as they were in their settled and regular state, to attempt giving a description of them during the vicissitudes to which they were very lately so frequently and rapidly subject, and from the effects of which they have not yet recovered, so as to regain their wonted regularity and steadiness.

It is scarcely necessary to call upon the reader for his admiration of the wonderful proofs which these manufactories afford, of the skill, industry, enterprise, and wealth of the inhabitants of this country. In ancient or in modern times, there is no parallel to what England exhibits at this moment; and such is the state of apparent perfection to which most of her manufactures have reached,—so completely subservient to their will have her inhabitants brought the most refractory and stupendous powers of nature,—such a practical demonstration have they exhibited of the truth of Bacon's maxim, that knowledge is power; that did we not com-

pare what our manufactures are now with what they were half a century ago,—did we not perceive, even while we are pronouncing them perfect, new improvements taking place, by means of which, either their quality is bettered, or human labour is saved; and did we not know that our countrymen, in their capital, their industry, their skill and experience, possess almost inexhaustible sources of improvement, we should be inclined to pronounce, that the manufactures of England had reached that point of perfection, beyond which they could not advance.

In the following Table is given the number of families engaged in trade, manufactories, &c. in each county, and the annual amount of income derived from these sources, as returned to the House of Commons.

CHAP. X.

Fisheries.

The fisheries of England consist of those which are carried on in the rivers and on the coasts; and of those which are carried on at a distance from the country. Of the latter description, are the Newfoundland fishery, the Greenland and Davis' Straits fishery, and the South Sea fishery. Of the former description, the most important are the salmon fishery, and the fishery for herrings, mackerel, pilchards, oysters, turbot, &c.

Although salmon are taken for sale in most of the rivers in England, yet there is no river in which they are very abundant, or the source of considerable profit, except the Tweed. In this river, there are 41 fisheries of considerable value, besides smaller ones. The former extend upwards about 14 miles from the mouth. Above this, they are of trifling importance. The rent of the whole is nearly £16,000. The expense attending the servants' wages, nets, boats, &c. amounts to nearly £10,000 more. The number of boats employed is generally about 80, and of men between 300 and 400. Nearly the whole of the salmon caught on the Tweed was formerly sent up to the London market pickled; but within these 20 years it has been sent up packed in ice.

The herring fishery on the coasts of England is not nearly so extensive and valuable as that on the coast of Scotland; and within these 20 years it has been on the decline. It may be considered as extending from the coast of Scotland to the entrance of the English Channel, on the east and south-east side; but Yarmouth is generally regarded as the centre of it. Herrings are also caught on the west coast of England, but not in such numbers. The commerce in herrings is of very ancient date. Madoc, in his History of the Exchequer, relates, that in 1105, the town of Dunwich was obliged to deliver 24,000 herring to the king; and, in the reign of Edward III., the herring fair of Yarmouth (which had existed for some time before) was regular by statute. The Mediterranean market for this fish, however, does not appear to have been opened, or at least to have been of much importance, before the beginning of the 17th century; and while it continued uninterrupted, the fishery off the coasts of England were extensive and lucrative, notwithstanding the Dutch greatly participated in them. In the year 1760, 205 vessels were employed on the Yarmouth coast, of from 30 to 100 tons; and it was computed that about 6000 men, women, boys, and girls, were supported by this fishery. At the same time, between 30 and 40 vessels sailed from Folkstone, Hastings, &c. on the herring fishery. For about 20 years preceding 1760, the annual capture of herrings on the Norfolk coast, was above 47,000 barrels, of which 35,000 were exported. In 1762, it had declined greatly, only 94 vessels being employed on the Norfolk coast. In the year 1812, there were at Yarmouth, not on tonnage bounty, only five ships, of the burden of 267 tons, with 30 men. These caught and cured 500 barrels; and on shore there were cured 1086. At this period, there were on tonnage bounty three ships, the tonnage of which was 170 tons, and the crew consisted of 37 men and boys. The number of barrels cured by them was 2132. The number of barrels of white herrings landed or cured on shore 4378; and 1915 branded for bounty—none were exported. At Whitehaven, the other English station appointed by the act for the encouragement of this fishery, there were, in 1812, 4691 barrels of white herrings landed or cured on shore; 347 barrels branded; and 3013 exported. The cause of the great decline in this fishery is sufficiently obvious. The demand for cured herrings in the principal market for them, the Roman Catholic countries in the south of Europe, was interrupted, and nearly destroyed, in consequence of the war; while the other market, the West Indies, where they are used as food for the slaves, is supplied more cheaply from Scotland. Besides, from the increase of wealth and luxury, the home consumption, notwithstanding all the attempts that have been made to extend the use of this fish, has also diminished.

The mackerel fishery is entirely confined to the supply of the home market. They are principally caught between Yarmouth on the east and north, and the coast of Hampshire on the south and west, being seldom found in any abundance to the north of Yarmouth, and to the west of the Hampshire coast, being in a great measure neglected for the pilchard fishery. The principal market for mackerel is London, where, on an average, upwards of 1,000,000 are sold annually.

The chief pilchard fishery is along the coasts of Dorset, Devonshire, Cornwall, especially the last. The pilchard, Fowey, Falmouth, Penzance, and St Ives, during the flourishing state of this fishery, having exported a far greater quantity than all the other ports of these counties. But this trade, depending for its prosperity on the same causes as the export trade in herrings, has declined very much latterly. The annual export on an average of 10 years, from 1747 to 1766, was about 30,000 hogsheads from the four ports just mentioned; whereas, in the year 1782, it had fallen to about 12,000 hogsheads. Even in this declined state, it afforded employment to 30,000 fishermen, besides the seamen employed in carrying the fish to foreign markets, and 4000 or 5000 people connected with the shore business of the fishery. At one period, the Cornwall pilchards were so much in request in the Italian States, that the orders from them for lead, tin, copper, &c. were often

Statistics.
conditional, that if such a quantity of pilchards could not be sent, the other articles would not be received.

At present, the pilchard fishery is in a much worse state than it was even in the year 1782. Dartmouth and Falmouth are now its principal seats. In the former, the number of vessels employed in catching the fish, and conveying them to market, is upwards of 500. At Falmouth, the number is rather greater.

The pilchard fishery is principally carried on at Colchester in Essex, Wells, Faversham, Milton, the Swales of the Medway, Queenborough, Rochester, Sea Salters, Pool, Tenby in Pembroke-shire, and Port Inon in Glamorganshire. The Colchester oysters are the most famous. Most of these are brought from the little creeks between Southampton and Chichester, and are only fattened at Colchester. The oyster fishery at Poole is very considerable, supplying the London market for two months every season; about 40 sloops and boats being employed in this traffic, the receipts generally averaging between L7000 and L8000. The Bristol, Bath, and Gloucester markets, are supplied chiefly from Port Inon; 200 fishermen, and five or six sloops, being engaged on the oyster fishery there. It is calculated, that about 10,000 people are employed in this fishery along the coast of England.

The other fisheries on the coast are comparatively of little importance; they consist principally of turbot, cod, lobsters, &c. The fisheries for the two latter are chiefly on the east and north coasts, while the most extensive and valuable turbot fisheries are along the coasts of Norfolk, Suffolk, Essex, and the English Channel.

We are not in possession of any complete and authentic documents, by means of which we can lay before our readers an account of the total number of vessels and men employed in the fishing trade of England at the present time; but, in the year 1785, there was laid before the Treasury, by the commissioners of the customs, an account of the total number of ships and vessels, their tonnage, and number of men, belonging to each respective port in South Britain, that traded to or from foreign ports, coastwise, or were employed as fishing vessels, including each vessel, her tonnage, and men but once, from which we shall extract what relates to the fishing vessels.

Carry forward 875 10,680 3729

The Newfoundland fishery seems first to have been attempted about the year 1736; but no English colony was settled on the island till the year 1758. The details respecting it are either not very important, or not well ascertained, till the year 1791, at which time we found, from a judicious tract, entitled, "The Importance of the British Plantations in America," that the English made, one year with another there, about 200,000 quintals of fish, which, at twelve shillings the quintal, amounted to L120,000. This was deemed all clear gain, as the oil procured from the fish paid for salt, &c. In the year 1763, there were employed in this fishery 177 ships, of the burden of 17,268 tons, navigated by 2531 men, besides 116 ships, which brought out salt, or came in ballast to purchase the fish. In this year there were carried to foreign markets 493,654 quintals of cod, besides 1172 trecies of salmon. Towards the commencement of the American war, the Newfoundland fishery seems to have been on the decline, there having been in the year 1769, 334 fishing vessels; in 1770, 363; in 1771, 369; in the year 1772, 306; in 1773, 262; and in 1774, only 254. After the termination of the American war, and till nearly the commencement of the first French revolutionary war, the fishery revived; there having been in 1784, 236 fishing vessels; in 1785, 256; in 1786, 250; in 1787, 306; in 1788, 390; in 1789, 304; in 1790, 292; in 1791, 245; and in 1792, 271.

The prosperity of this trade depended, in a very considerable degree, on our being at peace with the south of Europe. This will sufficiently appear from the following official document: In the year 1790, there were exported from Newfoundland, 684,421 quintals of dried fish, of which 581,824 went to the south of Europe; and 6221 barrels of wet fish, of which 3667 went to the same parts. In the year 1791, there were exported 720,147 barrels of dry fish, of which 623,083 went to the south of Europe; and 7011 of wet fish, of which 4338 went to the same parts. These were years of peace; but in the year 1798, there were exported only
The South Sea whale fishery was not followed in this country till about the year 1776, where there were equipped 15 vessels of about 170 tons each. As the Americans had carried on this fishery before this period, four American harpooners were sent out in each vessel. The first voyage was not very successful, as they got only between forty and fifty tons of blubber, yet the manner of its being pursued during the war from L. 35 to L. 70 per ton, were sufficient to encourage the merchants to persevere in the business. In 1778, 19 vessels were sent into the South Seas; but from some cause, not explained, in the following year, 1779, the number to four; and it continued under 10 till the year 1785, when 11 vessels were sent out: in 1788, the number of vessels were 42, and their burden 8637 tons; till the year 1781, all the vessels belonged to London; after that, Liverpool, and some other of the out-ports, began to participate in the trade.

In 1793, the first year of the war, the number of vessels was 38: the war, however, seems to have affected this fishery; for, in 1797, the number was reduced to 23; and it continued nearly the same till the conclusion of the war. At present, the number is again raised, there being usually between 33 and 40 vessels, the tonnage of which is between 12,000 and 14,000, and the number of men employed between 800 and 1000.

From this brief sketch of the fisheries of England, both domestic and foreign, it is sufficiently obvious that they are not carried on with nearly the same degree of enterprise and spirit which is displayed by the English in almost all the other branches of their trade. Yet frequent attempts have been made to extend and improve them; companies have been formed by individuals, and bounties granted by government. Whence then does it happen, that the fisheries of this country, especially those on the coasts of the island, are so imperfectly and languidly pursued? Probably, because in other branches of trade and commerce, we have made such great advances, and can secure, or at least render probable, such large profits, that the comparatively small profits which the fisheries offer to our commercial ambition, are not sufficient to turn the adequate capital aside into that channel.

In considering the trade of any maritime country, it naturally divides itself into three parts; the coasting trade, the inland trade, and the foreign trade: the last, strictly and properly speaking, constitutes its commerce. The two first are versant either about the supply of the inhabitants of the country, or they indirectly constitute part of its foreign commerce. They must be considered in the latter light, when they merely bring goods for the ports of shipment; and in the former light, when they contribute towards the interchange of articles of domestic consumption.

The coasting and inland trade of England, though of great importance and value, even when considered as confined to articles of domestic consumption, cannot be brought within an estimate at all approaching to the truth, the details being much too extensive and scattered, and many of them too minute.

The coal trade comprises one of the most considerable branches of the coasting trade of this country; the coal ships on the east coast alone, belonging to Newcastle, Shields, Blyth, Hartley, Whitby, Sunderland, Scarborough, &c. amounting to about 1500 sail, of from 150 to 400 tons; the number of men employed in these vessels cannot be fewer than 12,000.
In the year 1796, a committee of the House of Commons drew up a report on the London Docks, from which the following particulars respecting the coasting trade of London is extracted, which may serve to point out the great increase of the branch of trade, so far as relates to the metropolis; and we may safely infer a similar increase in the coasting trade between the different provincial ports. In 1700, the coasting vessels (including their repeated voyages) which arrived in the port of London, were only 5,562; their tonnage, 218,100. In the year 1750, 6,996, and their tonnage 511,680; in 1790, the number of vessels 9,278, and their tonnage 947,600; in 1795, the vessels 11,964, and their tonnage 1,199,400: and in 1796, the vessels were 10,620, and their tonnage 1,325,532. From the report of the select committee, on the improvement of the port of London, in 1795, it appears, that in the year 1797, the number of vessels, (including their repeated voyages), which entered the Thames from the provincial ports, was 10,781, and their tonnage 1,250,828; and in 1798, the number of vessels was 10,183, and their tonnage 1,250,449. Considering, with respect to their tonnage, there were of coasters in 1798, 5578 vessels (including their repeated voyages), under 100 tons; 800 from 100 to 150 tons; 98 vessels from 150 to 200 tons; and 14 from 200 to 400 tons; the total number of vessels being 6344, and their tonnage, amounting to 500,636, besides 3289 colliers (including repeated voyages), the tonnage of which, on an average of 229 tons to each vessel, amounted to 749,813, making the total of vessels, as before stated, to be 10,183, and the total of tonnage 1,250,449. If from these we deduct one tenth as the proportion of Scotland, we shall gain a pretty accurate idea of the coasting trade from the provincial ports of England to the metropolis, in the year 1798. Of these coasters, the port of Hull sent nearly one-fifth, (not including the colliers), there being 100 from Hull, and 896 from the other ports of England, and 32 from the ports of Wales.

There are no data on which a calculation can be grounded of the value of the coasting trade of England. In the evidence lately given before the House of Commons, on the establishment of a new chartered marine insurance company, it was calculated that the value of the goods carried coastwise, was one half of the value of the exports and imports; but it is not possible to ascertain whether this calculation comes near the truth or not.

It is still more difficult to form an estimate of the inland trade of England; nor can any person even imagine its extent, who has not considered the wonderful and numerous facilities of conveyance, which, springing at first from the commercial enterprise and wealth of the country, have in their turn served to increase and extend it. The state of the roads in almost every part of England; the almost infinite number of carriages, waggons, &c. which are either conveying our merchants and manufacturers, or their goods, without interference, and in the most regular, certain, and expeditious manner; but, above all, the numerous canals by which the country is intersected, in almost every direction, must be taken into the account, if we wish to entertain any thing like an idea of this subject. Nor shall we yet be doing justice to our country, if we do not recollect that all these facilities of conveyance are the work of little more than half a century. The highways of Britain were not equal in goodness to those of foreign countries, when the peace of Aix-la-Chapelle was concluded. From this time to the death of George II. great exertions were made to improve the state of the roads; and during the first 14 sessions of the reign of George III. the various road laws were collected into one act, and no fewer than 452 acts were passed for repairing the high ways of different districts. Since that period, not a session has passed in which acts for repairing and improving the high ways have not been enacted.

The evidence respecting the extent and rapid increase of our inland trade, derived from the numerous canals which have been made, since the commencement of the present reign, is not less striking and unequivocal. A very early attention was paid to the navigation of our rivers; and from the Revolution, to the death of George II. many streams had been rendered navigable; a still greater number, however, have been rendered commodious to internal commerce, during the present reign, besides the more valuable improvement of canals; nineteen acts during the first fourteen sessions of this reign having been passed for making artificial navigations; and subsequent sessions have witnessed nearly an equal attention to this mode of facilitating internal commerce.

It would carry us far beyond our limits, even to enumerate all the canals which now exist in England. On this subject, we must refer our readers to the article Inland Navigation; and content ourselves with remarking, that nearly all the great manufacturing towns are connected with one another by means of canals; that by them they can receive most of the raw materials, which they respectively work up; and that by far the largest proportion of the manufactured articles are dispersed over the kingdom, or sent to the ports whence they are embarked to foreign parts, by means of inland navigation.

The foreign trade of this country is generally considered of much more importance than its domestic trade; but this idea appears to us to be erroneous: the foreign trade is undoubtedly much more imposing in its aspect, and the extent of it is more easily ascertained; but the real value of the domestic trade, if properly investigated, will be found to be much greater. Let us only reflect on the population of England and Wales, which is upwards of ten millions; and on the industry and wealth of that population: our foreign customers are undoubtedly more numerous, but they are far behind what may be called the domestic customers in industry and wealth. Even on the very moderate computation, that the average annual expense of each individual of the ten million inhabitants, amounts only to L.20, the annual domestic consumption will amount to the enormous sum of L.200,000,000.

We come now to the consideration of the foreign trade of England; and in describing it, we shall enumerate the most important and material articles which England imports from each particular foreign country,
and which she exports into each particular foreign country; and give a statement of the value of the exports and imports, where they have been ascertained, and also of the number of vessels employed in each branch of foreign trade. We shall conclude this part of our subject, by a statement of the whole exports and imports, and of the tonnage, both domestic and foreign, which annually enter or leave our ports.

The principal imports from Denmark are hides, bar iron, kelp, furs, tar, and timber and boards of different kinds: the principal exports to this country are, hardware goods, lead, tin, coals, earthen-ware, glass, salt, cotton goods, woollen goods, hats, tanned leather, refined sugar, drugs and dye stuffs, tobacco, &c. The real value of the exports to Denmark, from 1798 to 1803, was on an average about half a million; from 1803 to 1807, when the attack on Copenhagen took place, the value of the exports varied from L 2,000,000 to L 6,000,000. The number of vessels employed in the trade to Denmark, in times of peace, was generally (including their repeated voyages) of English vessels 200, of foreign vessels 800.

To Russia. The principal articles of import from Russia are pearl and potash, bristles, cordage, flax, hemp, black, flax, iron, linens, pitch, tar, tallow, timber, &c.; the principal articles of export are coals, salt, salt ammoniac, lead, tin, hard-ware, earthen-ware, glass; woollen, cotton, and silk goods; refined sugar, dye stuffs, &c. The official value of the imports from Russia is generally about L. 2,000,000; of the exports to Russia, about half that amount. The number of vessels employed in the trade to this country in times of peace, was generally (including their repeated voyages) of English vessels about 500, and of foreign vessels about 100.

To Sweden. The principal articles of import from Sweden are flax, iron, pitch, tar, timber, &c. of export to Sweden, coals, lead, tin, hardware, earthenware, salt, cotton and woollen goods, sugar, coffee, tobacco, &c. The official value of the imports from Sweden is generally under L. 500,000; of the exports to Sweden under L. 100,000. The number of English vessels employed in this trade is generally about 50; and of foreign vessels about 250.

To Poland. The principal articles of import from Poland are corn, particularly wheat, pearl and pot ashes, timber, &c.; of exports, hardware, cotton goods, sugar, coffee, drugs, spices, &c. The official value of the imports are generally about L. 300,000; of the exports under L. 50,000. The English vessels employed in this trade are about 30, and the foreign vessels about 20.

To Prussia. The principal articles of import from Prussia are corn, particularly wheat and oats, flax, hemp, pearl and pot ashes, timber, &c.; of export, salt, woollen and cotton goods, hardware, earthenware, glass, sugar, coffee, and various articles of East India produce. The official value of the imports is frequently near a million; of the exports rather less. The number of English vessels employed in this trade are about 160, and of foreign vessels, generally about the same number.

The imports from Germany, as well as the exports from that country, are very numerous; the principal articles of the former are corn, flax, hemp, linens, rags, skins, wines, timber, &c.; of the exports, hardware, plated goods, salt, earthenware, tanned and wrought leather, gloves, hats, cotton and woollen goods, silk goods, watches, cabinet ware, coaches, &c. Besides colonial and East India produce to a large amount. The official value of the imports from Germany and the exports to it, has varied very much, at different periods of the war; and the average value of each, during the war, was much greater than before its commencement, as much of the trade between England and the continent was carried on through Germany. This will be sufficiently apparent from the following statement: In the year 1791, the official value of the imports from Germany was about L.600,000; of the exports, rather under L.2,000,000; whereas, in the year 1800, the imports were upwards of L.2,000,000, and the exports rather more than L.12,000,000. From this instance, which, however, it must be confessed, is an extraordinary one, the extreme difficulty may be conceived of giving any thing like an accurate statement of the average value of the imports and exports of England to and from any particular country, as they existed during the strange and unparalleled war from which we have just emerged; though there is no difficulty in giving an average statement of the whole amount of the imports and exports, from and to all parts of the world, during that war. The number of English vessels employed in the trade to Germany is generally about 200, and of foreign vessels rather more.

The principal articles of import from Holland are, To Holland. To France, to be articles of luxury, such as wines, brandy, lace, cambrics, lawns, silks, trinkets, &c.; of exports, cotton goods, hardware, cutlery, lead, tin, copper, besides a vast deal of East and West India produce. The official value of the imports from France during the year 1789, when the Revolution commenced, was rather more than L.500,000; and of the exports about L.1,200,000, of which about L.800,000 consisted of English manufactures, and the remainder of foreign produce. In the same year, the number of English vessels employed in this traffic (including their repeated voyages) was nearly 900, of foreign vessels about 400.

The principal articles of import from France used To France. To Spain, are, barilla. To Spain, oil, cochineal, fruits, wool, cork, dyewoods, wines, brandy, silk, &c.; of exports, hardware, earthen-ware, broad cloths, leather, hats, baizes, &c. In time of peace, the official value of the imports was usually about L.700,000, and the exports nearly the same; and the number of English vessels engaged in the trade about 200, and of foreign vessels about 50.

The principal articles of import from Portugal are, To Portugal, brimstone, cork, drugs, and gums; wines, fruit, dyewal stuffs, hides and skins, &c.; of exports, hardware, coals, glass, earthen-ware, woollen, cotton and silk manufactures, hats, and East and West India produce; the value of the imports is generally about L.80,000; of the exports, rather more than L.1,000,000; the number of English vessels employed, about 250; of foreign, about 50.

The usual articles of import from Italy, are barilla, To Italy, brimstone, cork, oil, fruits, silk, &c.; of export, hardware, plated-ware, earthen-ware, woollen goods, cotton goods, pitchards, herrings, leather, and East and
West India produce. In time of peace, the official value of the imports was usually about L.500,000, and of the exports nearly the same; and the number of English vessels engaged in the trade about 200; of foreign vessels, very few were employed.

To Turkey.
The imports from Turkey consist principally of carpets, textiles, stuffs, fruits, silk, &c.; of exports, the principal are hardware, cotton and woollen goods, watches, and East and West India produce. The official value of the imports is about L.200,000; of the exports nearly the same. The English and foreign vessels employed seldom exceed 50.

To Ireland.
The imports from Ireland to England are very numerous; they consist chiefly of corn, provisions, linen, hides, &c. The principal articles of export are coals, woollen, cotton, and silk manufactures; hats, h Barbados, earthenware, salt, glass, and East and West India produce. The value of the imports vary from L.2,000,000 to L.3,000,000; and the exports from L.5,000,000 to L.4,000,000, of which one half generally consists of foreign produce. The ships employed, (including, as usual, their repeated voyages,) are between 4000 and 5000.

To North America.
The principal articles of import from North America, are flour, provisions, masts, timber, cotton wool, tobacco, rice, tar, pitch, and pearl ashes, indigo, furs, &c.; of export, woollen and cotton goods to an immense amount; hardware, earthenware, books, hats, leather, linen, shoes, paper, &c. The value of the exports, especially those to the United States, has varied much latterly, according to the state of political relations between the two countries. It has been as high as L.12,000,000; the value of the imports is comparatively trifling. The vessels employed in times of peace are about 500, most of which are foreign.

To South America.
South America has lately become of great consequence to the English merchant and manufacturer; the emigration of the court of Portugal to the Brazilis, and the circumstances which have occurred in the Spanish provinces, having opened the trade to this country. The principal imports from South America are cotton-wool, skins, cochineal, logwood, indigo, Brazilwood, sugar, drugs, &c. The principal exports are, woolens, silk and cotton goods, linen, leather, hardware, hats, earthenware, &c. The value of the imports from the Brazilis alone, amounted in 1810, to between L.2,000,000 and L.3,000,000; and about 160 ships were employed in the trade.

To the West Indies.
The principal articles of import from the West Indies are sugars, rum, coffee, pepper, ginger, indigo, drugs, cotton, &c. of export, hardware, provisions, woollen and cotton goods, hats, glass, earthenware, leather, shoes, ready made clothes, herring, &c. The real value of the imports varies from L.8,000,000 to L.12,000,000; and of the exports from L.6,000,000 to L.12,000,000. The ships employed are about 600; the tonnage about 180,000; and the seamen about 15,000.

To the East Indies.
The principal articles of import from the East Indies, China, and Persia, are ten, spices, raw silk, muslins, nankeens, sugar, indigo, cloths and other spicies, opium, quicksilver, drugs, gums, rice, saltpetre, &c. The principal articles of export are woollen goods, tin, hardware, lead, copper, bullion, clocks; watches, hats, millinery, coaches, cabinet and upholstery goods, &c.

From the year 1708 to 1811, there was exported to India bullion to the value of L.29,588,210; and merchandise to the value of L.55,528,886; making the total exports to India, during that period, L.65,112,096; and during the same period, there was exported to China, bullion of the value of L.18,295,092; and merchandise to the value of L.24,012,650; making the total value of the exports to China L.37,307,742; and the total value of the exports both to India and China, from 1789 to 1811, L.102,449,844. On an average of 1811, 1812, and 1813, the goods exported to India and China, amounted to L.1,000,000; and on an average of the same years, the total produce of the articles sold at the East India Company's sales amounted to about L.6,000,000.

In the year 1771, the tonnage employed in this trade was 61,000; by an act passed in the year 1772, the company was restrained from building, till their shipping was reduced to 45,000 tons: this reduction took place in 1776, when they began to rebuild. In 1792, their English built ships amounted to nearly 80,000 tons; at present the tonnage is upwards of 100,000; the burden of the ships varying from 500 to 1500 tons.

This trade has hitherto been wholly vested in the hands of the East India Company; but on the expiration of their present charter, the trade to the East Indies will be thrown open, under certain regulations: that to China will still continue the monopoly of the company.

Such is a brief, and necessarily an imperfect, abstract of the principal branches of English commerce. In consequence of the political relations in which this country has stood for the last twenty years with the continent of Europe, and for the last eight years with the United States of America, it is not possible to present a fair average statement of its regular trade, either with Europe or America. The following official statements, however, will serve to give us a clearer insight into the real value of the exports.

Real value of exports, on an average of three years ending 1807, to the continent of Europe, L.17,801,232; to Ireland, Guernsey, &c. L.6,415,425; to Asia, L.3,308,991; to Africa, L.1,278,346; to the United States of America, L.12,136,811; to other parts of America; and the West Indies L.10,599,514; making a total, on the annual average of three years ending 1807, of L.51,540,224; if from this sum we deduct L.4,000,000 as the value of the exports from Scotland, it will leave about L.47,000,000 as the value of the exports from England.

Real value of exports, on an annual average of four years, ending 1811, to the continent of Europe, L.20,963,806; to Ireland, &c. L.7,128,304; to Asia, L.3,229,375; to Africa, L.725,019; to the United States, L.6,168,059; and to the other parts of America and the West Indies, L.17,393,533; making a total of L.58,657,372; from which, deducting L.4,000,000, as the probable amount of the exports from Scotland, there will remain L.54,100,000 as the amount of the exports from England. This comparative statement of the exports of two series of years, will be sufficient to shew how much the value of our exports varied both to the continent of Europe and to the United States, particularly to the latter.

The following statement shews the real value of the imports into England alone, (exclusive of those from India and China,) and of the exports from England, distinguishing foreign from English produce exported.

In the year ending 10th October 1806, there were imported articles to the value of L.48,908,645; and exported of foreign goods, L.9,005,129; and of English goods, L.39,895,218. In the year ending the 10th of October 1807, there was imported, L.49,947,300; exported of foreign goods, L.9,679,202; and of English goods, L.39,241,554. And in the year ending
It may well be conceived, that the total amount of the tonnage, employed in the domestic and foreign trade of England, is very great. In the year 1800, there were 12,198 vessels belonging to English ports; of the burden of 1,466,602 tons; and navigated by 105,037 men and boys. In the month of September 1813, there were belonging to the English ports 16,602 vessels; of the burden of 2,029,637 tons; and navigated by 127,740 men and boys. In consequence of the fire at the Custom-house, the English and foreign ships that entered inwards, and cleared outwards, for the year 1813, cannot be calculated; but in 1812, there entered inwards, (including their repeated voyages,) of English ships, 10,756 of the burden of 1,310,150 tons, navigated by 72,269 men and boys; and of foreign ships 2536, of the burden of 469,606 tons, navigated by 23,950 seamen; and in the same year, there cleared outwards, (including their repeated voyages,) of English ships, 11,177, of the burden of 1,368,520, and navigated by 83,473 seamen; and of foreign ships 2536, of the burden of 490,206 tons, and navigated by 23,940 seamen. About one-sixth part of the whole English shipping belongs to the port of London.

The circulating medium of England consisted of the precious metals, and of bank notes, convertible at sight into the precious metals, until the year 1797, when, in consequence of a great run on the Bank of England, (the only chartered bank in the country;) an act of parliament was passed, freeing the bank from the obligation of paying coin for their notes.

The money coined in the reign of Charles II. amounted to L.7,524,105; in that of James to L.2,737,637; by William to L.10,311,963; by Anne to L.2,619,626; by George I. to L.872,529; by George II. to L.11,966,576; and by George III. down to the year 1800, to L.62,945,663. Since the year 1800, very little has been coined; and at present, the circulating medium consists almost entirely of the notes of the Bank of England, and of the provincial banks.

The amount of the value of the Bank of England notes in circulation, in the year 1718, was L.1,583,930; in the year 1761, L.3,863,299; besides post bills to the value of L.136,520; in the year 1791, they had reached the sum of L.11,099,000; but, in February 1797, they were reduced to L.8,640,000; in 1802, they were L.17,054,450; and, at present, they are upwards of L.29,000,000.

The natural and obvious consequence of the withdrawing of the metallic currency of the kingdom, was not only an increase in the amount of Bank of England notes, but also an increase in the number of provincial banks, and in the amount of the value of their notes. In the year 1797, the number of country banks, issuing notes in England, did not reach 200; in 1808, they were nearly 600; in 1811, 649; in 1812, 625; in 1813, 643; and in 1814, 699. The average circulation of each of which cannot possibly be rated at less than L.30,000, which will make the total amount of the circulation of the provincial notes upwards of L.29,000,000; but it is probably much greater.

Even this circulating medium, great as it is, would be totally inadequate of itself to carry on the immense trade of this kingdom. In London, the great seat of mercantile transactions, exchanges to a very large amount are effected, without the intervention of any circulating medium, by means of brokers, who buy and sell for different merchants, and set off the various articles against each other. As a proof how small a sum of circulating medium is employed to transact business to a very large amount in the metropolis, it may be mentioned, that in the clearing house, in Lombard Street, where the clerks of the different banking houses meet for the purpose of exchanging drafts, drafts to the amount of upwards of L.4,000,000 are frequently presented in the course of the day, while bank notes only to the amount of about L.200,000 are required to pay the balance.

The principal sources of the revenue of England are the duties of customs and excise; the stamp-duities; the land-tax, and assessed taxes; the post-office duties; and the income tax. The revenue is divided into the permanent taxes, and the war taxes; the latter, laid on during the revolutionary wars with France, consist of the income-tax, and of additional duties of customs and excise.

About the commencement of the 17th century, the produce of the customs amounted to nearly L.150,000, of which upwards of L.100,000 was collected in the ports of London. In the act of union, the customs of Scotland are reckoned at L.30,000, and those of England at L.1,341,539. In the year 1800, the gross produce of the customs of England was L.5,551,608; in the year 1804, L.10,189,238; in the year 1810, the permanent revenue of the customs was L.9,552,835; and the temporary, or war customs duties, amounted to L.3,599,251; making a total of L.13,152,085; and in the year 1813, the gross produce of the permanent duties of customs was L.9,837,542; and the war duties, L.3,523,205; making a total of L.12,830,747. The revenue of the customs is collected in England at the rate of L.5,14. 2d. on the gross amount.

The Excise, which consists of inland duties, or taxes on articles manufactured or consumed, originated in the year 1626; but was not actually established till the year 1643. In the reign of George I. the excise duties were rendered perpetual. In the year 1800, the gross produce of this branch of the revenue amounted to L.11,994,199; in the year 1804, to L.29,985,641; in the year 1810, the permanent duties of excise amounted to L.18,925,545; and the war duties to L.6,082,870; making a total of L.25,414,524. For the year 1813, the following Table exhibits the particulars of the excise duties:

* The particulars of the custom receipts for 1810, could not be made out, in consequence of the fire at the Custom-house, which destroyed all the documents.
England.

Account of the gross actual receipt in Money, and net produce of the Excise Consolidated Duties, Unconsolidated Duties, Temporary War Taxes, and Tobacco and Malts, annual, in England, for the Year ending 5th January 1814.

The expenditure of collecting the excise duties is at the rate of L.2:11:10 per cent on the gross amount. The gross produce of the stamp duties, in the year 1800, amounted to L.2,698,365; in 1804, to L.3,429,697; and, in 1810, to L.5,311,593. The following table exhibits the particulars of the Stamp Duties for 1813:

</table>

The rate at which the gross revenue of the Stamps is collected, is L.3:1:9 per cent.

**Land-tax.**

The land-tax, which at first was an annual tax, was made perpetual in the year 1799, and offered for sale to the proprietors of the land, or to any other persons who chose to purchase it. In the course of the first year after this act, upwards of L.13,000,000 was purchased; and on the 23d of February 1813, rather more than one-third was redeemed. In 1813, the gross produce of the land-tax was L.1,272,256: the net produce L.1,127,078.

The assessed taxes consist principally of the house and window taxes. In the year 1800, these together, with the land-tax, amounted to L.4,451,900; in 1804, to L.5,747,374; and in the year 1810, to L.7,210,384. In the year 1813, the assessed taxes, independently of the land-tax, amounted to L.5,903,811 net; and to L.5,903,811 net: the rate at which the gross produce of the land and assessed taxes is collected, is L.4:5:8 per cent.

**Post Office.**

The present establishment of the Post Office was traced in outline in 1642; but there was no regular Post Office till 1654. In the year 1724, the revenue from this source amounted only to the sum of L.96,382: the plan of conveying letters by the mail coaches, was begun in 1784, the revenue the year before amounting to L.159,000. In the year 1800, the gross produce of the Post Office was L.995,354; in 1804, L.1,178,408; and in 1810, L.1,574,543. In the year 1813, the gross produce of the inland post was L.1,532,980: of the foreign post, L.126,647; and of the twopenny post L.93,299; making a total of L.1,754,926: the net produce was L.1,236,148: the revenue is collected at the rate of L.25:9:4 per cent, on the gross receipts.

The income or property tax is 10 per cent. on all Property incomes, (with some exceptions and modifications); in the year 1800, when it was only 5 per cent. it amounted to L.4,677,766; in 1804, to L.5,752,556; in 1810, when it was 10 per cent. it amounted to the sum of L.12,514,369; and in 1813, the gross produce of it was L.13,016,011. Of the following Tables, the first exhibits the amount of the income of England and Wales, in the years 1806, 1808, and 1810, derived from all the different sources, except the public funds, public offices, &c. on which the income tax was levied; and the second, the amount of income in 1810, derived from trades and professions, showing the particular sums derived from every rate of income, from L.50 to L.5000 and upwards.

The following particulars, strictly speaking, relate to the finances of Great Britain; but as the revenue derived from Scotland is comparatively very trifling, and as it is impossible to ascertain what proportion of the expenditure belongs to that country, and what to England, it is thought proper to give them under the present article.

Revenue in 1813.

Total revenue of Great Britain for the year 1813, L.79,448,111: Loans paid into the Exchequer, including six millions for Ireland, L.35,050,574. Exchequer bills issued between 5th January 1813, and 5th January 1814, and not redeemed within that period, L.41,554,000: Navy, Victualling, and transport bills issued, L.3,099,740. Total income of the consolidated fund, which consists principally of the customs, excise, stamps assessed taxes, &c., as it stood 5th January 1814, L.41,527,304: Total charge upon it, L.41,555,752. Net produce of the permanent taxes of Great Britain, in the year 1813, L.37,597,835; in the year 1814, L.38,893,027.

The following statement shews the particulars of the expenditure of Great Britain for 1813, and also the state of the national debt in February 1814. For further particulars respecting the national debt, see Dext, National.

The Navy of Great Britain forms its principal bulwark and pride; and its increase and present strength are not more astonishing than the increase and present amount of the wealth of the kingdom, which we have just exhibited. At the death of Queen Elizabeth, the total number of ships belonging to the navy was 42, the largest mounting 40 guns, and the whole navigated by 8376 men. At the death of King William, the total number of ships was 256, of which 193 were of the line. At the death of George II. it had not increased much, there being only 136 ships of the line. At the commencement of the war in 1793, there were 156 sail of the line; in January 1801, 395 sail of the line; and in the month of April 1814, there were in commission 727 ships of war; of which, 187 were of the line, 34 from 50 to 44 guns, 145 frigates, 124 sloops of war, 8 bomb and fire ships, 184 armed brigs, 39 cutters, and 49 schooners; besides which, there were in ordinary, repairing, and building, a number, making the total 1022, and of the ships in the line 250. The seamen and marines employed at this time amounted to 140,000.

Till the war which has just terminated, the generals and soldiers of Great Britain certainly did not bear so high a character as her seamen, but their exploits during that war has raised them to an equality; and the exertions of this country in increasing her troops, far surpassed those she had put forth at any former period. In the year 1775, the whole regular troops amounted only to 38,190; in 1783, to 90,205; in 1793, to 38,945; and in 1801, to 149,865; all these, however, except the last, were periods of peace. At the termination of the present war, Great Britain maintained upwards of 28,000 cavalry, 7500 foot guards, 191,000 infantry, and 71,000 militia. The English militia amounted to upwards of 51,000: besides these, there were the local militia, volunteer corps, foreign troops, artillery, &c.
The population of England and Wales was long a subject of great uncertainty, till it was at last determined by the result of an act of parliament in December 1800, which directed a general enumeration of houses, families, and persons. From this enumeration it appeared, that there were in England 1,472,876 inhabited houses, occupied by 1,787,520 families; and that the total number of persons was 8,331,434: While in Wales there were 108,033 inhabited houses, occupied by 118,503 families; and that the total number of persons was 541,546. In the year 1811, a similar enumeration took place, of which the following are the results:

### Inhabited houses in England
- England: 1,678,106
- Wales: 119,398

### Number of families in England
- England: 2,012,591
- Wales: 129,756

### Houses building in England
- England: 15,188
- Wales: 1,019

### Uninhabited houses in England
- England: 47,925
- Wales: 5,095

### Families engaged in agriculture in England
- England: 697,353

### Families engaged in trade in England
- England: 923,578

### Families engaged in other occupations in England
- England: 391,450

### Families engaged in other occupations in Wales
- England: 8,016,000

From a comparison of the population of England in the years 1801 and 1811, it appears that it had increased 14.4 per cent. during that period; while the population of Wales had increased 15 per cent. The population of the manufacturing districts had increased in much the greatest proportion; in 1801, the population of Lancashire was 672,731; in 1811, it was 856,000. In 1801, the population of the west riding of Yorkshire was 509,933; in 1811, it was 675,100. There is also reason to believe, that the population of England and Wales, between 1785 and 1795, increased nearly in the same proportion as it did between 1801 and 1811. The proportion of sexes was much the same in 1811 as in 1801, that is, about 10 males to 11 females of the resident population. The following Table exhibits the increase between 1801 and 1811, in a more particular point of view:

</table>

Till the enumerations of 1801 and 1811, it was generally supposed, that there were not more than 5½ persons to a house in London, and the other great towns; but the result of these enumerations proves, that, taking the whole of England and Wales, the proportion of inhabitants to a house is about 5½, while in the towns it varies very considerably, from 4½ to 9½.

Although there are no certain data, by means of which the population of England and Wales can be accurately ascertained, previous to the enumeration of 1801, yet the following Table, constructed on the best information regarding this subject, it is presumed, exhibits nearly the state of the population, at different times, prior to 1801:

<table>
<thead>
<tr>
<th>Years</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>1700</td>
<td>5,475,000</td>

</tbody>
</table>

The average number of registered burials was stationary for 21 years, from 1780 to 1800; the average number being about 192,000 per annum. From 1800 to 1805, the average was 194,000; and from 1805 to 1810, the average number was 196,000.
In the following Table, the number of baptisms to 100 marriages, at different periods, from 1760 to 1810, is given:

</table>
In treating of the population of England, it would be improper not to notice the state of the poor, and the mode by which they are supported; and yet our limits compel us to be very brief on this subject. By the 42d of Elizabeth, chap. 2, every parish is bound to provide for its own poor; and authority was given to justices of the peace, &c. to rate every parish at such a weekly sum of money, as they should think necessary for this purpose. In 1776, a return was made to parliament of the total expenditure for one year, on account of the poor, from which it appeared, that the sum expended was L1,530,804; and that there were 1970 workhouses capable of accommodating 89,775 persons. In 1786, another return was made, from which it appeared, that the expenditure for the poor had increased to L2,004,238. In the year 1803, a very detailed return was again made, from which the following particulars appeared: The number of persons maintained in workhouses was 83,405; the expense incurred, L1,016,445; the number of persons relieved out of work-houses was 926,248, besides 194,058, who were not parishioners; the sum expended was L1,061,446. The number of persons relieved in and out of work-houses was 1,039,716, which was about 12 per cent. of the resident population. The total sum raised by the poor's rate, and other parochial rates within the year, ending Easter 1803, was L5,348,205. The average rate in the pound was, in England, 4s. 4d.; in Wales, 7s. 1d.; and the average of England and Wales, 4s. 5d. No return has been made since the year 1803; but the amount of the poor's rate at present cannot be much less than L8,000,000.

CHAP. XI.

Constitution, Government, and Laws; Civil and Religious.

The English government is distinguished from that of other nations, principally by this circumstance, that in it the right of making and that of enforcing the laws, or the legislative and executive powers, are distinct and separate. The legislative authority is vested, by the constitution of the kingdom, in the Parliament, which consists of King, Lords, and Commons. It is not accurately and satisfactorily ascertained, at what precise period the Parliament, as it is now constituted, was formed; that is, when the Commons first began to compose a distinct assembly from the Lords; but the generally received opinion is, that the Parliament was, on the whole, much the same as it now is, so long ago as the 17th year of King John, A. D. 1215.

With respect to the manner and time of the assembling of Parliament, it is usually and regularly summoned by the King's writ and letters, issued by the advice of the privy-council, at least 40 days before it begins to sit. The Parliament cannot meet of its own authority, it being a part of the royal prerogative to convene it at such time and place as the King shall deem proper. If there should be no Parliament in being at the death of the King, the last Parliament re- 
vivés, and is to sit again for six months, unless his successor shall dissolve it.

The constituent parts of Parliament, as has been already remarked, are the King and the Three Estates (as they are denominated) of the realm, the lords spiritual, the lords temporal, and the commons. The king and the lords spiritual and temporal sit in one house, which is called the House of Lords; and the representatives of the people in another, which is called the House of Commons. When Parliament assembles at the beginning of a session, the King always meets them in person, or by commissioners appointed to represent him. He also has the power to prorogue or dissolve it. Besides these royal prerogatives, as they respect Parliament, the King possesses the privilege of rejecting any bill that may have passed both Houses, and consequently preventing it from being enacted into a law.

The lords spiritual, as a constituent part of Parliament, consist of the two archbishops and 24 bishops of England, and four bishops of Ireland. The English archbishops and bishops sit in the Upper House, from their holding, or being supposed to hold, certain baronies under the King.

The lords temporal consist of all the peers of the realm, in their several degrees of duke, marquis, earl, viscount, and baron. The duke is so styled from the Latin, Princeps, a leader or prince; the title of marquis is derived from the Gothic, and signifies the commander or guardian of a march or frontier. The titles of earl and baron are also from the Latin, and signifies simply eminent men. Viscount is derived from the Latin, and signifies the lieutenant of the count or earl.

The bishops are not, strictly speaking, peers of the realm, but only lords of Parliament. The number of the lords temporal is indefinite, the King possessing the privilege of increasing them at his pleasure. Some sit in the Upper House by descent; some by creation; the Scotch and Irish peers by election.

The House of Commons consists of knights, citizens, and burgesses, respectively chosen by counties, cities, and boroughs. The number of representatives sent to Parliament, for England, Wales, and the town of Berwick, is 519. The Scotch and Irish representatives increase the number to 658 members. No person can vote for a Knight of the shire, unless he possess a freehold estate of the annual value of 50s. Neither beneficial leases for a term of years, nor copyhold estate, give the right of voting. A leasehold, however, vested in an individual for life, does. Every candidate for the representation of a county, must have a clear estate of freehold, or copyhold, of the value of L600 per annum, unless he be the eldest son of a peer, or a person qualified as a knight of the shire.

The citizens and burgesses in Parliament are the representatives of the mercantile and trading interests, as the knights of the shire are of the landed property. Many boroughs, however, with no trade, and some with very few persons entitled to vote, return members to Parliament, while some of the most populous and flourishing places in England, as Manchester and Birmingham, send no representatives. The right of voters in boroughs varies according to the charters, customs, and constitutions of the respective places. Every candidate to represent a city or borough, must possess a free estate, of freehold or copyhold, to the value of L300 per annum, unless, as in the case of candidates for counties, he be the eldest son of a peer, or of a person qualified as a knight of the shire.

As soon as the Parliament is summoned, the lord chancellor sends his warrant to the clerk of the crown in Chancery, who then issues out writs to the sheriffs of every county, for the election of all members to serve for that county, and for every city and borough in it, which possesses the privilege of returning mea-
bers to Parliament. But in case a vacancy for any place occur while Parliament is sitting, the speaker of the House of Commons issues his warrant for the election of a new member. As soon as the place and time of election are fixed, all soldiers must be removed to the distance of two miles or more, and must not return till the poll is over. No lord of Parliament, or lord-lieutenant of a county, has any right to interfere at elections. When a poll is demanded, it must commence immediately, and be continued from day to day, for at least seven hours each day, till it be finished. The sheriff, or returning officer, has the right of granting a scrutiny, if it be demanded. The persons returned are the sitting members, until the House of Commons, upon petition, shall adjudge the return to be illegal. All petitions against sitting members are referred to a select committee of 15 members of the House of Commons.

On the first day of the meeting of every new Parliament, the lord steward of his Majesty's household administers the necessary and usual oath to the members present; and then executes a commission, empowering certain members to administer the same oath to others. Every member is obliged to attend his duty in the House, unless he can shew a sufficient excuse for his non-attendance; if he do not, he is ordered into the custody of the sergeant-at-arms, which is attended with the expense to the party of about L.5 a day. No member can vacate his seat, unless he accept of an office under the crown. The offices of stewards of the chiltern hundreds (from which neither honour nor profit are derived) are generally accepted for that purpose. As soon as the seat in Parliament is thus vacated, these offices are resigned, and are then ready for any other members, who wish to vacate their seats. Commissioners for prizes, agents for regiments, officers of the excise and customs, clerks of the treasury, &c. and every person who holds any office under the crown, created since 1795, or any pension during the pleasure of the king, or for any term of years, are ineligible to sit in Parliament.

The Parliament thus constituted, consisting of King, Lords, and Commons, is invested with absolute power. Besides the power of making and repealing all laws, it can new-model the succession to the crown; alter the established religion of the land; and even change the constitution of the kingdom, and of Parliament itself. The privileges of Parliament are very large, and indeed are not strictly defined. Amongst them, that of freedom of speech is the most important and salutary. It is particularly demanded of the King in person by the Speaker of the House of Commons, at the opening of every new parliament. Another privilege consists in the protection of the persons of the members of both Houses from arrest. This privilege, however, does not extend to treason, felony, nor to the case of writing and publishing seditious libels. The franking of letters is also a privilege common to the members of both Houses of Parliament. There are some privileges peculiar to the House of Lords. As they constitute the highest law court in the kingdom, they have a right to be attended by the Judges, the Sergeants at Law, and the Masters in Chancery. Every peer, on obtaining licence from the king, can constitute another Lord of Parliament his proxy, to vote for him in his absence. The peers also enjoy the right of protest; that is, each peer may enter on the journals of the House his reasons for dissenting from any vote which passes contrary to his wishes. The privileges peculiar to the House of Commons relate principally to the raising of taxes. All grants of subsidies or parliamentary aids, by the ancient indisputable privilege and right of the House of Commons, begin in their House; nor do they ever suffer the Lords to make any change in the money bills, which are sent up to them.

On the opening of every session of parliament, the Mode of king, either in person or by his commissioners, addresses opening both Houses, in a speech from the throne. After this, the regular business of Parliament commences. In the House of Lords the Lord Chancellor generally presides as speaker, and regulates their proceedings. The House of Commons always elect their own speaker, who must, however, be presented to the king for his approbation. The speaker of the House of Commons cannot give his opinion, unless the House be resolved into a committee, where he loses, for the time, his character of speaker. The speaker of the upper House is always at liberty to take part in the debate. The Commons cannot proceed to business unless 40 members present. Two ing. peers, however, besides the speaker, are sufficient to constitute a House of Lords. All bills, except money bills, may originate in either House. A member first gives notice of his intention to move for leave to bring in a bill. When leave is given, it is read a first time; and at a convenient distance, a second time. After each reading, the speaker puts the question, whether it shall proceed any further? In the House of Commons, the speaker cannot vote unless the ayes and noes be equal, and then his casting vote decides the majority. But in the House of Lords, the speaker votes with the House; and if the contents and non-contents be equal, the latter have the effect of an absolute majority. In the House of Commons, two tellers are appointed to count the votes on each side.

After the second reading the bill is committed, that is, referred to a committee, either select, or of the whole House. In the latter case, the speaker leaves the chair, and another person is appointed chairman of the committee. In a committee, each member may speak on the question as often as he pleases; whereas, during the regular sittings of the House, no person can speak more than once on any subject unless in explanation, with the exception of the member who made the motion before the House, who has the privilege of replying, at the conclusion of the debate. The chairman of the committee reports the bill to the House; after which it is read a third time; and one of the members is directed to carry it to the Lords for their concurrence. Here it goes through the same forms as in the other House. When the bills have passed both Houses, they are always deposited in the House of Lords, to wait the royal assent, except bills of supply, which are returned to the Commons. The royal assent is given either by the king in person, or by commission. When the royal assent in either way is given to a bill, then it becomes an act of parliament, and not before. The king, as well as each House of Parliament, possesses the constitutional power of rejecting any bill; but this power has not been exercised since the year 1692, when King William III. refused to pass the bill for triennial parliaments into a law.

Strictly speaking, no strangers have a right to be present in either House during parliamentary proceedings; but in fact, admission is easily obtained. When, however, a division is about to take place, strangers are obliged to withdraw. Till within a comparatively recent period, neither House would permit their debates to be published; but at present they are regularly and fully given to the public in the newspapers.
The duration of Parliament was formerly for three
years; but in the beginning of the 18th century, the
duration was extended to seven years. It seldom
happens, however, that Parliament sits out this pe-
riod.

It is not necessary that there should be the formal
pronouncement of an act to give it the force of a law;
but copies of it are usually transmitted to the chief ma-
gistrates throughout the kingdom. When a law is once
made, it cannot be repealed, amended, or dispensed
with, but by the same authority, and by going through
the same forms, by which it was enacted.

Each House possesses the privilege of adjourning it-
self; by which nothing more is meant than the contin-
uance of the session from one day to another. A pro-
gration is the continuance of Parliament from one ses-
tion to another. This is done by the king’s authority,
expressed by the Lord Chancellor in his Majesty’s pre-
sence, by commission from the crown, and sometimes
by proclamation. When Parliament is prorogued, bills
which had been begun must be resumed de novo in the
next session, and go through all the forms again before
they can pass into law. A dissolution, which is the ci-
vil death of parliament, is effected by the king’s will.

With respect to the executive power, and the rights
of succession to the throne of England, the fundamen-
tal maxim is, that the crown is, “by common law and
constitutional custom, hereditary; but that the rights of
inheritance may from time to time be changed or limited
by act of parliament, the crown still continuing heredi-
tary under those limitations.” The right of primogen-
titure amongst the males, and of the males in prefer-
cence to the females, is a constitutional rule in the de-
scent of the crown. Upon failure of the male line, the
crown descends to the eldest of the female issue, and
the heir of her body lawfully begotten, and not jointly
to the female issue of the same degree, as in common
inheritions. By the statute 12 and 13 William III.
ch. 2, the descent is limited to such heirs only of the
Princess Sophia, grand-daughter of King James I., as
are Protestant members of the church of England, and
are married to none but Protestants.

The queen consort has many prerogatives different
from other wives. She is a public person distinct from
the king, and is able to purchase lands, to convey them,
and to make leases, without his concurrence. In short,
the law considers her, in all respects, as a single wo-
man; but she is the king’s subject, and not his equal.
It is high treason to compass or imagine her death, as
well as that of the king. It is also high treason to vi-
olete her person, and in her likewise if she be consenting.
The law regards and protects in a similar manner, the
Prince of Wales, his consort, and the Princess Royal.
The king’s brothers, uncles, grandsons, and nephews,
take precedence of all the other nobility. They, as well
as the Prince of Wales, and the younger sons of the
king, sit in the House of Lords. By statute 12 George
III. ch. 11, no descendants of George II. (except the
issue of princesses married into foreign families,) can
contract matrimony without the previous consent of the
king; unless, being of the age of 25, they give a twelve-
months notice of such intention to the privy council,
and, before the expiration of that period, no disappro-
valion is expressed by Parliament.

By the constitution of this country, various councils
are allotted to the king, to advise him respecting public
measures. Besides the Parliament, which has been al-
dready mentioned, the peers of the realm are hereditary
councillors of the sovereign, and have a right to demand
an audience of him, to lay before him such matters as
they shall consider of importance to the state. The
judges also, are the king’s counsellors in matters of law.
But the principal council of the sovereign is his privy
council, the members of which are chosen by him, and,
on changes of administration, are seldom erased, though
those in opposition seldom attend. They are styled
right honourable, and are sworn to observe secrecy.
The lowest at the board pronounces his opinion first,
and the king, if present, concludes with declaring his
judgment.

The cabinet council, as it is called, consists of those
Cabinet ministers of state, who hold the highest rank and digni-
ty. The members are generally 9 or 11; consisting of
the lord chancellor, the lord privy seal, the lord presi-
dent of the council, the three principal secretaries of
state, the first lord of the treasury, the chancellor of
the exchequer, and the first lord of the admiralty. The
first lord of the treasury is considered the premier, or
prime minister of the country. It sometimes happens,
that the officers of first lord of the treasury, and the
chancellor of the exchequer, are held by the same per-
son. No part of the executive authority of the king is
vested in his privy council, the constant style of the law
being the king in council, and not the king and coun-
cil. The constitution does not recognise the cabinet
council. The king can remove his confidential servants,
or “the administration,” as it is usually termed, at his
pleasure.

The principal officers, who have the management of Principal
the political, military, naval, and financial affairs of
the kingdom, are the lord high treasurer, or lords commis-
ioners of the treasury; the principal secretaries of
state; the secretary at war; the commander in chief; the
lord high admiral, or lords commissioners of the
admiralty.

The business of the treasury, is to determine on all
matters relative to the civil list, or the other revenues of
the nation; to give directions for the conduct of all
boards, and persons entrusted with the receipt, manage-
ment, and expenditure of those revenues; to sign all
warrants for payments out of them, and generally to
superintend every branch of the revenue belonging to
his Majesty, or the public. Formerly, there was a lord
high treasurer; but for upwards of one hundred years,
the management of the treasury has been in com-
misson; the commissioners being the first lord of the
treasury, the chancellor of the exchequer, (to whom is
entrusted, in an especial manner, the revenue and ex-
penditure of the nation, and who generally takes the
lead on the ministerial side of the House of Commons,) and
three other commissioners. Since the union with
Ireland, the chancellor of the exchequer of that part of
the united kingdom, is, ex officio, nominated one of the
lords commissioners of the treasury.

There are three principal secretaries of state; the Secretary
secretary of state for the home department, who has state
management of, and control over, the internal affairs
of the kingdom, and from whom all directions and
commands to the lord lieutenants, sheriffs, and other
magistrates, issue; the secretary of state for foreign af-
fairs, who, as the name implies, has the management of
all correspondence and transactions with foreign na-
tions; and the secretary of state for war and colonies,
who has the management of the affairs of the colonies,
and to whom also is entrusted the supreme direction of
all warlike expeditions.

The commander in chief is at the head of the army.
Secretary at war, when there is no commander in
chief, (that is, when the king retains actually, as well as
virtually, the first military command in the country,)
superintends and controls the discipline, as well as the finance of the army; but when there is a commander in chief, (as there generally is,) he superintends the finance, as distinguished from the discipline of the army; he communicates with the troops in all matters that relate to the police, or law of the country. Some matters of pure discipline, however, are still transacted under his immediate authority; for instance, all that relates to the apprehension and escort of deserters, and in many more cases; though the measure originates with the commander in chief, much of the execution rests with the war office. On the other hand, some considerable branches of finance, (such as the local allowances to troops on foreign stations, and the barrack expenditure in general,) do not come under the war office.

Admiralty.

The special superintendence of the navy is seldom now entrusted to a lord high admiral; but a board of admiralty is appointed, consisting of a first lord, (who, generally, is not a naval officer,) and six subordinate members, among whom are admirals of known skill and experience. The duty of the admiralty is to consider and determine on all matters relative to the navy; to give directions for all services that are to be performed therein, both in its civil and naval branches; and generally, to superintend the naval and marine establishment. The duties of the commissioners of the navy are under the lords of the admiralty, to attend to all affairs regarding the civil establishment of the navy; to make contracts for civil stores, and distribute them; to prepare estimates; to direct all monies for naval services into the hands of the treasurer of the navy; and to examine and certify his accounts. The transport office, which was instituted in 1794, has the charge of the transport service, of sick and wounded seamen, and of prisoners of war.

The duty of the Sovereign is expressed in his coronation oath, by which he swears to govern according to the statutes of Parliament, and the laws and customs of the kingdom; to cause law and justice, in mercy, to be executed in all his judgments; and to maintain the Protestant reformed religion.

The constitution of this country ascribes to the Sovereign the political attribute of absolute perfection. It is an ancient and fundamental maxim, that "the king can do no wrong;" by which is meant, that he cannot be made personally amenable for any wrong which he may actually commit, his minister being responsible, in all cases, for the acts of the Sovereign. By the constitution, also, the king never dies, since, immediately on the natural death of the Sovereign, the regal dignity is vested in his successor. Besides these attributes, the king is considered in law as the sole magistrate of the nation, all other magistrates deriving their power and authority from him; he has also the exclusive power of sending and receiving ambassadors, of making treaties, &c. and of declaring peace or war. By the statue of the 18 Car. II. chap. 6 he has the sole command of all fleets and armies, and of all places of strength in the kingdom.

As the king is considered the prosecutor in all criminal proceedings, he is invested, by the constitution, with the prerogative of pardoning offences. Another branch of the prerogative, is the power of issuing proclamations, by which laws already made are enforced. The other prerogatives of the king, are the power of conferring honours and dignities, either by writ and letters patent, as in the creation of peers and baronets; or by corporeal investiture, as in the creation of a knight, of creating new offices, and of regulating weights and measures, and coining money.

The maintenance of the king’s household, and the civil list, are supplied from the annual taxes. The revenues of the civil list consist at present of £500,000, granted by the 1st of George III.: £100,000 granted by the 17th of George III.; £60,000 by the 44th of George III.; £70,000 by the 52d of George III.; and £35,000 the surplus of excise fees, granted by 23d of George III., but which fluctuates with the general expenditure of the country: the total revenue of the civil list is thus about £1,065,000. There are 8 classes of expenditure from the civil list. The 1st class comprises pensions and allowances to the royal family. From the year 1804 to 1812, these amounted to about £320,000. By additions made in February 1812, in consequence of the king’s illness, they were increased to the sum of £390,000. In the second class, are comprised allowances to the lord chancellor, speaker of the House of Commons, judges of the King’s Bench and Common Pleas, barons of the Exchequer, and justices of the Court of Great Session in Wales: in all about £25,000. In the third class, are comprised salaries to foreign ministers; these of course vary according to the extent of our relations with other powers. Under the fourth class, are comprised bills in the departments of the lord chamberlain, lord steward, master of the horse, and master of the robes: about £250,000. In the fifth class, salaries in the above departments about £75,000. The sixth class, comprehends pensions and compensations to old servants, and late ministers at foreign courts: about £120,000. The seventh class comprises small fees and salaries to the amount of about £36,000. And the last class comprehends salaries to the commissioners of the Treasury, and chancellor of the exchequer: about £9000. Besides payments in all these classes, there are occasional payments, which may amount on an average to £150,000.

It has already been mentioned, that the king is the chief magistrate in the country. The principal subordinate magistrates are, the high sheriffs, coroners, justices of the peace, constables, surveyors of highways, and overseers of the poor. The high sheriffs are elected annually by the lord chancellor, the chancellor of the exchequer, the judges, and privy council. The powers and duties of the high sheriff are very great; he determines the election of knights of the shire, and, as the keeper of the king’s peace, is the first man in the county, having the power of calling out the posse comitatus, or summoning every person above fifteen years old (except peers) to attend him, on pain of fine and imprisonment for disobedience. In his judicial capacity, he may hear and determine all causes of 40s. value. In civil cases, he is to serve the writ, to arrest, and take bail; to summon the jury in all cases, and to see judgment executed. He has under him, the under sheriff, bailiffs, and gaolers.

In every county there are usually four coroners, and coroners, sometimes six. They are chosen by the freetholders. Their duty is to inquire into the manner and cause of the death of every person who is supposed to have died by violence, suddenly, or in prison. The inquiry is to be made, on view of the body of the deceased, by a jury, over whom the coroner presides. If, by the coroner’s inquest, any one is found guilty of murder or manslaughter, he is to commit the offender for further trial. The next denomination of magistrates are justices of the peace, the principal of whom is the custos rotulorum, or keeper of the records of the county.
The municipal law of England is divided into the unwritten or common law, and the written or statute law. The common law consists of general customs, the particular customs of certain parts of the kingdom, and those particular laws which are observed by custom only in certain courts and jurisdictions. The proceedings and determinations in the ordinary courts of justice are directed by general customs, or the common law, properly so called. Of these customs the judges are deemed the repositories, the judicial decisions of their predecessors being their guides. The written laws of the kingdom consist of those statutes which are made by the king's majesty, by and with the advice and consent of the lords spiritual and temporal in parliament assembled. If the common law and statute differ, the former gives place to the latter; and an old statute is superseded by a new one; but if a statute that repeals another be itself repealed, the first statute is revived without any formal words for that purpose.

Courts of justice in England, are either such as possess general jurisdiction throughout the whole realm, or special jurisdiction only in particular places. Of the former, there are the courts of common law and equity, the ecclesiastical courts, the courts military, and the courts maritime. The court of King's Bench is the supreme court of common law in the kingdom; it is so called, because the Sovereign was understood to judge in person; and its jurisdiction extends to the whole kingdom, the presiding judge being denominated Lord Chief Justice of England. Besides the chief judge, there are three puisne judges. The authority of this court extends to criminal as well as civil cases; the latter is divided into the crown side, the former the pleas side, of the court. It is a court of appeal, into which may be removed all determinations of the court of Common Pleas and of the inferior courts; but from it an appeal lies to the House of Lords, or to the Court of Exchequer. The court of Common Pleas determines all civil actions between man and man, as distinguished from "the pleas of the crown," which term comprehends all crimes and misdemeanours. In this court there is one chief and three puisne judges. The Court of Exchequer, so termed from the ancient mode of counting upon a chequered board, is a court of law and equity also. It consists of two divisions. The receipt of the exchequer, which manages the royal revenue, and in which all causes relating to it are determined; and the court, or judicial part of it, which is again subdivided into a court of equity and a court of common law. From the equity side of this court, appeals lie immediately to the House of Peers. The whole number of judges is twelve; to all of whom, intrinsic and important points of law, that may occur in any trial, are referred. They also sit in the House of Lords, in order that they may assist them with their opinion and advice, when that House acts in its judicial capacity. Formerly the judges were dependent on the crown; but his present Majesty began his reign with declaring, "that he looked upon the independence and uprightness of the judges as essential to the impartial administration of justice—as one of the best securities of the rights and liberties of the subjects—and as most conducive to the honour of the crown." Upon this an act was passed, by which the judges are to be continued in office notwithstanding the demise of the crown; nor can they be removed, but by a joint address of both Houses of Parliament to the king. The High Court of Chancery is the most important of all the king's civil courts of justice. It has its name from the judge presiding in it, who is styled Lord High Chancellor, because the highest point in his jurisdiction consists in cancelling the king's letters patent, when they are granted contrary to law. The Lord Chancellor takes precedence of every temporal lord. By his office he is speaker of the House of Lords. To him belongs the appointment of all the justices of the peace throughout the kingdom; and he is patron of all the king's livings under the yearly value of £20 in the king's books. He is also the general guardian of all infants, idiots, and lunatics. The Court of Chancery, in which the Lord High Chancellor alone sits, and determines without a jury, judges causes in equity, in order to moderate the rigour of the law, to defend the helpless from oppression, and especially to extend relief in cases of accident, fraud, and breach of trust. From this court an appeal lies immediately to the House of Peers, which is the supreme court of judicature in the kingdom. From its decision there can be no farther appeal.

The courts of assize act as auxiliaries to the courts already mentioned: They are composed of two or three commissioners, who are sent round the kingdom twice every year, except in the four northern counties of Northumberland, Durham, Cumberland, and Westmorland; in which the assizes are held only once a year. The trial by jury, handed down from our Saxon ancestors, is the most noble feature in English jurisprudence, and is justly regarded as the safeguard of the lives, liberties, and property of the nation. In civil cases there are two kinds of juries, special and common. Special juries were originally introduced, when the causes were too intricate for the discussion of ordinary freeholders. In forming a special jury, the sheriff attends with his freeholders' book, and the proper officer takes indiscriminately 48 of the freeholders, 12 of whom are struck off by each of the attorneys on both sides. A common jury is returned by the sheriff, who gives in a list containing not less than 48, nor more than 72 jurors, whose names are put into a box, and the 12 first drawn out are sworn on the jury. The jurors may be challenged by either party. Each of the 12 men composing the jury is sworn separately, well and truly to try the issue between the parties, and a true verdict to give according to the evidence. The
pleadings are then opened by the counsel for the plaintiff; after which, the evidence is gone through in support of the case; the counsel on the other side next opens the adverse case, and likewise adduces evidence in support of it; after which, the party who began is heard in reply. One credible witness is sufficient to establish a fact. No man can be a witness in his own cause. The evidence being gone through on both sides, the judge proceeds to sum up the whole to the jury, in the presence of the parties, their counsel, and all others, in open courts. He also gives his opinion to the jury in matters of law arising upon the evidence. If the jury think it necessary, they retire to consider of their verdict. They are kept without meat, drink, fire, or candle, (unless by permission of the judge,) till they are unanimously agreed. When they are agreed, they return back to the bar, and deliver their verdict; that is, they find either for the plaintiff or the defendant. The judgment of the court follows the verdict of the jury; and where the judgment is not suspended, or reversed, execution follows; but the writs of execution must be sued out within a year and a day after judgment is entered. Such are the proceedings in civil cases.

Courts of criminal jurisdiction, are either those of a public and general authority throughout the kingdom; or such as are private and special, being confined to particular parts of the realm. The highest criminal court is the high court of parliament. In it the greatest offenders, whether peers or commoners, are prosecuted and punished by trial or impeachment. An impeachment is a presentment to the House of Lords, by the Commons, in Parliament assembled. A peer may be impeached for any crime, and a commoner for a capital offence, as well as for high misdemeanours. No pardon, under the great seal, is pleadable to an impeachment by the Commons. In cases of impeachment, after evidence is gone through, and counsel heard, each peer declares, on his honour, whether the accused is guilty or not guilty of the crimes laid to his charge, and he is acquitted or condemned, according as the majority of the peers are for or against him. It has already been mentioned, that the Court of King's Bench, on the crown side, takes cognizance of all criminal cases. The High Court of Admiralty takes cognizance of all crimes and offences committed either upon the sea, or upon the coasts. The criminal courts of local jurisdiction, are the courts of oyer and terminer, or courts of assize, held by the judges on the circuit, attended by the justices of the peace of the county wherein the assizes are held; and the general quarter sessions of the peace, which must be held in every county, once in every quarter of a year. It is held before two or more justices of the peace, one of whom must be of the quorum. The jurisdiction of this court extends to all felonies and trespasses; but murders, and other capital felonies, are usually referred to the assizes.

The regular and ordinary mode of proceeding against a criminal, is, in the first place, by arrest. The usual mode of making an arrest, or of apprehending a person, is by a warrant, granted under the hand and seal of a justice, on the party requiring it making oath concerning the crime committed: but arrests may be executed by officers, without warrant, against persons whom they find in the act of committing a breach of the peace. When an offender is arrested, he is taken before a magistrate, who dismisses him if the charge appears groundless; but if otherwise, he is either committed to prison, or admitted to bail, that is, he must give sureties for his appearance to answer the charge against him. On an accusation of treason, or of murder, as well as in many other cases, no bail can be taken; where it is admissible, the law directs it not to be excessive. After the commitment or bail of an offender, follows his prosecution, or formal accusation, which is first before the grand jury: this is the only institution of the kind in Europe. The grand jury is composed of freeholders and gentlemen of the first respectability in the county. It consists of 24 good and lawful men, of whom not fewer than 12, nor more than 23, are to be sworn to discharge the duty which the law imposes on them. The difference between the duty of a grand and petty jury consists in this, that the former hears only the evidence on the part of the prosecution, whereas the latter hears the prisoner's defence and witnesses also. As soon as the grand jury is sworn, the judge delivers to them his charge, remarking on the different subjects of their inquiry, and reminding them of their duty. If after having heard the evidence in support of the accusation, contained in the bill of indictment before them, they are of opinion that the accusation is groundless, they indorse the bill with the words "not a true bill," or "not found," and the party is discharged of course; but a new indictment may be preferred to a subsequent grand jury. But if they are satisfied of the truth of the accusation, they indorse upon it, "a true bill." The indictment is then said to be found. Twelve of the grand jury, at least, must assent to the accusation of the party. There is also a method of proceeding, in criminal cases, at the suit of the king, without a previous presentment to a grand jury, which is by way of information; either partly at the suit of the king, and partly of the subject, or in the name of the king alone.

If the offender, on the bill of indictment being found, does not appear after being required to surrender himself at five county courts, he is judged to be outlawed, or is rendered incapable of taking any of the benefits of the law, either by bringing actions or otherwise. When the offender appears in court, the bill of indictment is read to him; and he is then asked whether he be guilty or not guilty; if he confesses the crime, the court awards judgment; if he is obstinately mute, he is considered as convicted: if the prisoner plead not guilty, the sheriff of the county is to return a panel of jurors, who are to be sworn as they appear, to the number of 12. In all capital cases, the prisoner is allowed to challenge a certain number of them, without assigning any cause whatever; whereas the king can challenge no juror, without assigning a reason, to be allowed by the court. In cases of high treason, petit treason, and misprision of treason, two lawful witnesses are in general necessary to convict a prisoner; but in almost every other case, one witness is sufficient. After the evidence for the prosecution is gone through, the prisoner is called upon for his defence; and when this is finished, the judge sums up the evidence, pointing out the law to the jury, and uniformly instructing them, that if any doubt of the prisoner's guilt rest upon their minds, they are bound to acquit him. The jury then retires to consider their verdict, which must be given in open court. The unanimity of all the twelve persons is the peculiar characteristic of the English jury. If the prisoner is found not guilty, he is for ever discharged of the accusation; but if he be found guilty, the judgment of the court immediately follows, and he can only be pardoned by an exercise of the royal prerogative. This pardon must be under the great seal of England; the ne-
Statutes.

Execution.

Statute of the 13th, 20th, 16th, and 23d, of the reign of Queen Anne. The ministers of the established church are denominated the clergy, a term which comprehends all persons either in holy orders, or in ecclesiastical offices. The different orders of the clergy of the church of England, essential to the constitution of episcopal government, are those of bishops, priests, and deacons; but there are other officers, which, though not essentially necessary, have been gradually introduced, as archbishops, deans, prebendaries, minor canons, archdeacons, churchwardens, parish clerks, and the like. The episcopacy of England consists of the twenty archbishops of Canterbury and York, and 24 bishops, who, upon confirmation, may sit in Parliament; there is also the Bishop of Dover and Man, who has no seat in the House of Lords. The archbishop is the chief of the rest of the bishops, and all the inferior clergy in his province; he has the right to present to all vacant livings in the disposal of his bishops, if they are not filled in six months. The Archbishop of Canterbury enjoys some privileges above the Archbishop of York; to him belongs the privilege of crowning the kings and queens of England; and of granting special licences to marry at any time or place, to hold two livings, &c. He is styled the primate of all England, and precedes all persons except the royal family.

The province of Canterbury comprehends 1st, The bishopric of London, containing Essex, Middlesex, and part of Hertfordshire; 2d, The bishopric of Winchester, containing Surrey, Hampshire, Jersey, Guernsey, and Alderney; 3d, The bishopric of Litchfield and Coventry, containing Stafford, Derby, and part of Warwick and Shropshire; 4th, The bishopric of Lincoln, containing Lincoln, Leicester, Huntingdon, Bedford, Buckingham, and part of Hertford; 5th, Ely, containing Cambridgeshire: 6th, Salisbury, containing Wilts and Berkshire: 7th, Exeter, containing Cornwall and Devon: 8th, Llandaff and Wells, containing Somersetshire: 9th, Chichester, containing Sussex: 10th, Norwich, containing Norfolk, Suffolk, and a small part of Cambridgeshire: 11th, Worcester, containing Worcester and a part of Warwick: 12th, Hereford, containing Hereford and a part of Shropshire: 13th, Rochester, containing Kent: 14th, Oxford, containing Oxfordshire: 15th, Peterborough, containing Northampton and Rutland: 16th, Gloucester, containing Gloucestershire: 17th, Bristol, containing the city of Bristol, part of Gloucestershire, and Dorsetshire: 18th, Lincoln, containing Lindsey, Monmouth, Malmesbury, Brecon, and Radnor: 19th, St David’s, containing Pembroke, Cardigan, and Caernarvon: 20th, St Asaph, containing the greatest part of Flint, Denbigh, Montgomery, and part of Shropshire: and, 21st, Bangor, containing Anglesey, Caernarvon, Merioneth, and part of Denbigh and Montgomery.

In the province of the Archbishop of York, (who is termed the Primate of England), there is, 1st, The bishopric of Durham, which contains Durham and Northumberland: 2d, Carlisle, which contains great part of Cumberland and Westmorland: 3d, Chester,
The most numerous, as well as most laborious order of the clergy, are the deacons, curates, vicars, and rectors: formerly, the office of the deacon was to superintend, for the poor, the ancient donations to the church being assigned in three divisions, one to the poor, another for repairs, and the third for the clergy; at present, the office of the deacon is restricted to baptism, to reading in the church, and assisting the priest at the communion, by handing the cup, only a person cannot be ordained a deacon under the age of 23 years; a priest must be 24, and a bishop 30. A parish is one who has full possession of all the rights of a parish church: during his life, he has the freehold of the parsonage house, glebe, tithes, &c.; and for the most part, he has the right to all the ecclesiastical dues in the parish. If the prided, or great tithes, (such as those of corn, hay, &c.), be improperly, or converted into secular hands, the priest is termed a vicar, a name implying that they are the vicarii, or deputies of the rector; but if the tithes be entire, the priest is styled rector. A curate signifies one who is not instituted to the cure of souls, but exercises the spiritual office in a parish under the rector or vicar. The churchwardens superintend the repairs and decorations of the church, and the requisites for divine service, as well as collect the alms of the parishioners: they are annually elected at Easter. The sacristan, or sexton, originally had the care of the furniture and plate of the church; but the appellation is now applied to the grave-digger.

The annual income of the clergy of the church of England of all ranks, is supposed to be about £3,000,000; but the average annual income of the parochial clergy, or rectors, vicars, and curates, does not exceed £100. This income is derived principally from tithes; but it is a mistaken idea to suppose that all the tithes are in the hands of the clergy,—a great proportion of them belong to laymen.

The following Table exhibits the annual value of land in all the counties of England and Wales that is tithe-free, titheable, tithe-free in part, and tithe-free on payment of a modus, which is a very small and inadequate compensation.

The total figures are: £7,905,378 17s. 4d., £20,217,466 17s. 7d., £856,183 12s. 2d., £498,823 3s. 4d.
According to the last diocesan return, the total number of benefices in England and Wales (including 133 parishes), was 10,582; the number of non-resident parochial clergy was 5037, of which, however, 986 did not reside; and the number of residents 5897; the number of curates on livings where the incumbents were not resident, was 3926. The following Table exhibits the respective number of curates who had salaries from £10 per annum to above £70.

The convocation, the highest of the ecclesiastical courts, has already been mentioned; the next in dignity is the court of delegates, then the court of arches; there are also courts of audience, of prerogative, and of peculiar.

**Doctrines.**

The special tenets of the church of England are given in the 39 articles; but some of the most learned and conscientious of her divines have doubted whether they are Calvinistic or Lutheran.

**Dissenters.**

The law considers all persons as dissenters, who do not conform to the church of England in the established mode of religious worship, agreeably to the statutes of Elizabeth, chap. i.; and 15 Charles II. chap. 4. called the Acts of Uniformity. Latterly, however, and especially during the present reign, toleration has been greatly extended to dissenters from the church of England. The principal classes of dissenters are the Presbyterians, Independents, Papists, Methodists, Quakers, Swedenborgians and Unitarians. The Presbyterians and Independents are scattered throughout all England and Wales. The Papists, or Roman Catholics, are, for the most part, confined to Lancashire, Yorkshire, Staffordshire, Warwickshire, and Northumberland. The counties in which they are most numerous after these, are Durham, Cheshire, Norfolk, Suffolk, Kent, and Worcester. The total number in all these counties is supposed to be 200,000; in London, Surrey, and Middlesex, it is supposed there are 50,000; and in Bristol, Bath, Perth, York, Plymouth, Southamptont, Exeter, Gloucester, and in a few other places, 50,000 more; making in all 300,000. There are 900 Roman Catholic churche, of which 100 are in Lancashire.

The Methodists sprung up in England about 70 years ago; there are two grand divisions of them—the followers of Whitfield, who are Calvinists; these are not numerous, nor are they increasing; and the followers of Wesley, whose creed is Arminian. These have increased, and are increasing rapidly; their number in England, and Wales being nearly 150,000.

The society of Quakers, or Friends as they style themselves, also originated in England; but they are not numerous, and are probably not increasing, not being anxious to make converts. The greatest number of them is in London, and in the northern counties, particularly Lancashire, Yorkshire, and Westmoreland. The followers of Swedenborg are far from numerous. The modern Unitarians, of whom Dr Priestley may be considered the founder, are also far from numerous, being principally found in the North and West of England, and in the metropolis.

The civil and religious freedom which Englishmen enjoy, and by which they are proudly and happily distinguished from all the other nations of the earth, ought not, however, to be attributed solely to the constitution and laws under which they live. The same constitution and laws would fail to produce or ensure the same blessings in any other country; they would be a dead letter even here, if those who govern, as well as those who are governed, were not so enlightened, as to be firmly and deeply convinced; the latter, that if their civil or religious liberties were infringed, both their individual and national security and happiness would be endangered; and the former, that any attempt to infringe them would be in vain; and that, in fact, they as rulers, as well as the people over whom they rule, are much more secure and happy, while civil and religious liberty is entire, than if it were to be broken in upon.
CHAP. XII.

Language, Literature, Arts and Sciences, Education, Manners and Customs, Antiquities.

Language.

The language of England is radically Gothic, there being scarcely any words in it that can be traced to the Celtic, though there is no doubt that the original population of the country was Celtic. From the European languages of Latin origin and etymology, the French, Italian, and Spanish, but most particularly the French, the English language has derived a vast number of words, some of which are synonymous, or nearly so, with those of Gothic origin, and others have been incorporated, in order to supply the necessary terms for those new objects and ideas which civilization and science introduce. Of the Gothic dialects, the Belgic, Saxon, and Danish, the first has supplied more words than either of the others to the English tongue.

The Anglo-Saxon is the oldest dialect of the English language; in this dialect numerous manuscripts exist: one of the most classic authors is Alfred, whose translations of Bede and Boethius from the Latin into the Anglo-Saxon, have been published. At the time of the Norman Conquest, Norman French was introduced; but though it was the prevalent language among the nobility and warriors, it does not seem to have added many terms to the Anglo-Saxon, or to have changed the idiom or grammatical construction of the latter till a considerable time after that period. The constant intercourse, however, between England and France, and especially the conquests of Edward III., effected, in the 14th century, a change in vain attempted by the Norman Conqueror. Chaucer in poetry, and Sir John Mandeville in prose, are supposed to exhibit the first specimens of what may be termed the English language.

The advances of the language towards regular construction, during the fifteenth century, were very great; but from the reign of Edward VI. to the reign of Henry VIII., it underwent very little change or improvement. In the reign of Queen Elizabeth, as the English character then rose to a high degree of energy, vigour, and independence, in respect both to mental and moral qualities; so the language itself advanced to a degree of copiousness, dignity, force, and melody, which certainly has not been surpassed. That it did not lose any of those noble characteristics in the subsequent reign, is abundantly and unequivocally proved, by the common translation of the Bible, which was executed at that period.

Dignity and force continued in an especial manner to distinguish the language, till the restoration, when elegance and smoothness, in some degree, began to occupy their place. The style of Addison and his contemporary wits, has been justly celebrated for its neatness and simplicity; but it is undoubtedly deficient in energy, and by no means remarkable for grammatical correctness. Since that time, neither the English language nor style have undergone any improvements.

It is absolutely impossible, in this article, even to give a rapid and very brief sketch of English literature. It is distinguished from the literature of most of the continental nations, by unambitious good sense, solidity of judgment, and its application, in a more direct and certain manner, to the regulation of domestic and social life. Another grand feature of the English literature is, original genius, which shines forth so conspicuously in the writings of Shakespeare, Milton, Newton, and Locke. As contradistinguished from Scotch literature, the literature of England may be characterised as more learned, but less metaphysical.

Since the days of Newton, England has not been eminently distinguished for mathematical science; but towards the wonderful discoveries which the present age has witnessed in chemistry and the physical sciences, she has contributed an ample portion. The sciences connected with the healing art, have made great advances in England. Perhaps our surgeons are not superior to those of France, but our physicians are decidedly superior to the physicians of the continent, in their education, manners, professional knowledge, general respectability, rank and wealth.

Till the 16th century, this country had scarcely any native painters of merit; and it may be added, that it has been only during the reign of George III. that this art has met with such encouragement, or displayed much improvement. Even yet, in painting, engraving, and architecture, England has not made great advances. In music she is still more deficient; for while almost every nation on the continent, and her sister nations of Ireland and Scotland, have their respective national music, England is without it.

The higher and middle ranks of English give their children an expensive, and, in some respects, an excellent education; but till the institution of Sunday and Lancasterian schools, the education of the great bulk of the people was miserably and lamentably deficient. The most distinguished and extensive of the public schools are those of Eton, Westminster, St. Paul's, Harrow, Rugby, and Winchester. There are only two universities, at Oxford and Cambridge; at the former, classical learning is the favourite pursuit; at the latter, mathematical learning.

The distinguishing features of the English character, English are independence of mind and conduct; a reserve, timorous with austerity and pride; great fondness for domestic life; a disregard of, and contempt for, show and theatrical effect in what they say and do; and a decided preference for comfort to extravagance. In their diet, they are distinguished from most other nations, by the very large proportion of animal food which they consume; their favourite liquors are ale, porter, and port wine; for lighter wines, even the highest ranks have little relish. Tea, which is rarely met with on the continent, is drunk here in immense quantities by all ranks and classes of people. Their cookery and dress are particularly simple: with respect to the latter, it is impossible, by their dress, to distinguish the sons of the king from the plainest tradesman. The houses in England, as well as the persons of the people, bear unequivocal testimony to their minute and scrupulous regard to cleanliness. The prevalent disorders are, consumption, fevers, apoplexy, palsy, and inflamed; towards some of these, the uncertainty of the climate evidently contributes; towards others, the quantity of animal food and of strong liquors which are consumed. The cleanliness of persons, houses, and streets, however, which are everywhere met with, as well as the improvements in draining land, which have taken place during the last century, have rendered England a much more healthy country than it formerly was.

The English nobility and gentry spend a large portion of their time on their estates in the country; and many of them instruct and amuse themselves, as well
as benefit their fellow-subjects, by their attention to agriculture. Some of their country-seats are magnificent specimens of architecture; but, in general, they are rather commodious and elegant, than noble and extensive. The grounds around them, however, are almost in every instance laid out with great taste and effect.

The antiquities of England are generally arranged under six classes: 1. Celtic; 2. Belgic; 3. Roman; 4. Saxon; 5. Danish; and, 6. Norman. It is extremely doubtful, however, whether there are any antiquities really Celtic. Stonehenge is probably Belgic. The Roman antiquities are very numerous, and some of them in good preservation. A great many Roman inscriptions, altars, &c. have been found along the frontier-wall from the Western Sea to the Tyne; and traces of Roman roads are visible, from Richmond in Kent, through London, to Chester; from London to Lincoln; and from Norwich into Dorsetshire. The Saxon antiquities are chiefly sacred or secular edifices; the Danish are camps, and some castles, to the north of the Humber; and the Norman are castles and cathedrals, of which latter, those of Durham and Winchester may be particularly noticed.

In drawing up the preceding article, a great variety of books have been consulted for particular points, the titles of which it is not necessary to give here, since, unless on these points, they afford little or no information respecting the statistics of England.

The works principally consulted were, the agricultural reports of the different counties; the various travels in England; the Monthly Magazine, the early volumes of which contain many valuable papers on the manufactures, &c. of different towns and districts.

Much valuable information was also derived respecting the principal manufactures, from persons resident in the respective districts where they are carried on, and well acquainted with their present state. (w.s.)

ENGRAVING.

Engraving is the art of executing by incision on plates of metal, blocks of wood, &c. the representation of visible objects, with a view to the working off impressions from them. These impressions are called prints.

Although the art of engraving, considered in its application to the taking off impressions, be entirely a modern invention, the art itself was practised by the ancients from the earliest times, in various ways, such as in the decorations of articles of household furniture, and in the ornamens of dress, such as rings, clasps, &c. and in the embellishing of shields, helmets, swords, and other warlike instruments, as well as in the cutting of signets or seals. In these respects, however, it must be considered as a modification of sculpture.

It is probable that the first essays of engraving were only rude delineations expressed by simple outlines, such as are described by Herodotus as traced upon the shields of the Carians.

The dignity and importance of this art are universally acknowledged, whether considering the great advantages which society derives from its productions, or the high qualifications requisite for its professors. By means of it, the spirit of those splendid and costly productions of the art of painting, whether the representation of some great historical fact, or the embodying and giving a ‘local habitation’ to the sublime conceptions of the poet, which, without its assistance, would be for ever confined to the palaces of the great, is transferred upon paper in a cheap and portable shape, and multiplied and disseminated over distant countries to any extent. By it, portraits of the patriot, hero, and statesman, the philosopher and the poet, and others who have rendered themselves illustrious or useful to society, are also handed down to a grateful posterity; and in its humblest, though not least useful department, it is of great assistance to the philosopher and man of science, in the illustrations it affords to his written descriptions.

The book of Genesis contains the earliest record extant of the exercise of the art. In it, Bezaleel and Aholiab are mentioned as being professedly engravers, and are designated as “filled with wisdom of heart to work all manner of work with the graver, as well as to devise cunning works; to work in gold, and in silver, and in brass, and in cutting of stones, and to set them.” These and other arts employed by the Israelites in the decorations of the tabernacle, which they must have learnt of the Egyptians, shew a considerable advancement in the luxuries of life, and sufficiently warrant the conclusion, that the art was, even at that time, not in its infancy. Mention is also often made in the sacred writings, at a time much anterior to this, of the existence of signets, rings, and bracelets, which it is reasonable to suppose, however rudely executed, were engraved or carved.

But as the words that are used in the various ancient languages are not sufficiently definite, being equally applicable to carving, engraving, or chiseling, there can be but little deduced with certainty from them. A short view, therefore, of the relics of antiquity now extant, will convey a more precise idea of ancient engraving.

The hieroglyphic figures of the Egyptians are perhaps the most ancient remains of engraving on metal; they have been frequently met with, chiefly in the coffins of mummies, where they had been deposited as a sort of talismans. There are in the British Museum several fine specimens of these figures. One of these, which bears every mark of high antiquity, has been minutely described by Mr Strutt. (See Dictionary of Engravers.) “It represents Isis, and is carved in alto-relievo; the goddess appears standing on two crocodiles, holding in each hand two serpents, a creature like a scorpion, and a four-footed animal; from the tails of the crocodiles arise two ornaments; upon the top of one is a bird, but the representation on the top of the other is so much obliterated by time, that it cannot be ascertained. The flat part of the relief, together with the bottom edges and back part of it, are ornamented with figures and symbolical representations, executed entirely with the graver, without any other assistance; the backs of the crocodiles, and the heads of the four-footed animals, are also finished with the same instrument, in a very careful manner. It is four inches high, and three inches four-tenths at the bottom, from which it gradually decreases to the breadth of three inches at the top.”

Among the Etruscan antiquities at the British Museum, collected by Sir William Hamilton, are two specimens of the art of engraving at a very remote period; a representation of which forms the frontispiece to one of the volumes of Strutt’s Dictionary. “One of them,” as he describes it, “is a sheath to a parazonium or dagger. It is more than three inches and three-quarters wide at the top, and decreases gradually to an inch and a quarter at the bottom; its present length is eight inches and a half: the story engraved upon it appears to be taken from Homer. The trophy at the bottom is symbolical of war; above the trophy, two warriors are delineated, with a woman, who seems to accompany them with great reluctance, which I conceive may represent Paris and his accomplish conducting Helen to the ship, in order to make her escape to Troy; and at the top, the messenger, the servant of Menelaus, is relating to his lord the ungrateful behaviour of his Trojan guest. The figures are exceedingly rude, and seem to indicate the very infancy of the art of engraving, for they are executed with the graver only, upon a flat surface, and need only to be filled with ink, and run through the press, provided the plate could endure the operation, to produce a fair and perfect impression.”

He likewise gives the representation of another valuable specimen of ancient engraving, greatly superior in workmanship to the former. It is a patera, or instrument used by the priests in their sacrifices; and it is supposed, with great reason, to have belonged to an altar dedicated to Hercules, who is represented combating, as it appears to me, Hippolithe, the Queen of the Amazons, whose girdle he was enjoined by Erysichthon to unloose and take from her.”

But M. D’Anckerville, who has drawn up a descriptive catalogue of the antiquities collected by Sir William Hamilton, conceives it to represent Minerva lean-
Engraving

ing upon the head of that hero, and pressing him forward in the arduous path of glory; his bow and quiver are behind him. It is precisely seven inches in diameter, and about half an inch thick, apparently made of brass, but the ornaments and border are inlaid with silver. The figures and ornaments are carved in bas-relief, but the hair of the woman, and the smaller folds and ornaments of the drapery, are executed solely with the graver. The letters which compose the inscription must be read from right to left,—another strong proof of its great antiquity.

Another application of the art of the engraver, which seems to have been practised from the most remote antiquity, was the making of seals or signets, which were used as instruments of ratification. Mention of them is made in the sacred books as far back as the times of the patriarchs, as well as in the other early writings of the ancients. It is probable they were engraved on metal, and the impressions taken from them on wax, or some such soft ductile substance. In Hindostan, the art of engraving must have been known at a very remote period, as it appeals, as the specimens, which we have in this country, of the state of the art with them, described by M. Lanseer. As the date of one of them is ascertained, and as the execution displays considerable advancement, it shows that it must have been practised long before. "They are both deeds of transfer of land, engraved on tablets of copper, with seals appended to them of the same metal, which seem to have been struck like coins from an intaglio matrix. They are both in the Sanscrit language. One of them, which is now in the possession of the Earl of Mansfield, has been copied in fac-simile, and inserted, with an English translation, by Mr. Wilkins, into the first volume of the Asiatic Researches. It is dated 20 years before Christ; and it is further remarkable, that the date is expressed in Hindoo numerals, very much resembling the numerals now in use. The other, which is likewise engraved in the same manner, has the appendant seal impressed on a ponderous lump of copper, and attached to the deed itself by a massive ring of the same metal. The matrix must have been an engraving of no mean workmanship, and it exhibits a style of art similar, and not inferior, to the best of the present productions of the art of Hindostan; it is in all respects, and being bedded in the metal, is in high preservation. Its subject is mythological; its form a circle of about ten inches in circumference; and the weight of the metal on which it is stamped not less than four or five pounds. It was presented to Mr. Neave by Mirza Hazy, grandson of Shah Alum, the present Emperor of Hindostan, and was found in digging a foundation within the site of the ancient fort of Benares, on the Banks of the Ganges."

Die-sinking

by no means of so early a date as the engraving of seals, was practised at a very early period. It is uncertain whether the coining of money was invented by the Greeks or Lydians, though some suppose that the art was brought from Hindostan. The first Greek money is supposed to have been struck by Phidon, King of the Argives, whose reign is fixed by the Arundelian marbles at about eight centuries before the Christian era, or soon after the age of Homer. Many of the early Greek and Sicilian coins are beautiful, and in high relief; to this, however, the coins of Athens form a remarkable exception, being in a very inferior style of execution. The art seems to have been communicated to the Romans in the reign of Servius Tullius, about 460 years before the commencement of our era, by the Lydian colony settled in Etruria. The best of the Roman medals are the work of Greek artists, executed during the reign of Adrian.

The ancients, it has thus been shown, possessed as much knowledge in the art of engraving, as would have enabled them, had they known the method of working off impressions, to have carried it to any extent. And the same may be said with regard to printing, when we consider the stamps for pottery or packages, and other purposes, preserved in the Hamiltonian collection, having even gone so far as to form three lines under each other. Several of these have been described and copied by Strutt in his dictionary, and by Mr Lanseer in his Lectures on Engraving. They are in general a composition like brass, and some of them in stone. In some the letters are raised, the ground being hollowed out between them to the depth of the eighth of an inch, and cut in reverse like printing types, in order that in the impression they may appear in the right way. Others are cut in intaglio. One of these, copied by Strutt, supposed to be an amulet or charm, to secure the wearer from certain diseases or danger, has the following words, forming three lines, FELICIS AMVLLI GEMELI: another has the word HANNIAE: another cut in form of a heart, with the inscription, BASILEI SEXIS TEIT. Some have inscriptions at full length, others only monograms. There are others in the collection of Mr Douce; one in intaglio, engraved on stone, with which a Roman oralist marked his medicines; and another of metal, in cameo, containing the name of the Roman tradesman who used it, TITUS VALAGINI MAVRI. Many more specimens will be found in the antiquities of Father Montfacon, Franciscus Gori, and others, who have treated on this subject.

With regard to the state of the art amongst our British and Saxon ancestors, little is known. Like other savage nations, they possessed the art of making rude incisions on their warlike instruments, as the remains found in their ancient tumuli sufficiently testify; and their coins are evidently impressions from engravings cut on iron or steel. Under Alfred the Great, the art seems to have met with great encouragement; and, accordingly, it attained to very considerable perfection in the making shrines, and marking the tombs of saints and other pious uses, which are said to have been wrought in gold, silver, and other metals, adorned with engravings and precious stones, and to have been the admiration of all that saw them. There is still preserved in the museum at Oxford a valuable jewel, richly adorned with a kind of work resembling filigree, in the middle of which is seen the half-figure of a man, supposed to be St Cuthbert. The back of this curious remnant of antiquity is ornamented with foliage, very skilfully engraved.

Dunstan, Archbishop of Canterbury, is said to have practised both designing and engraving, as well as the working of images and other things, in gold, silver, and brass. However, from the specimen that remains of his skill in drawing, preserved in an ancient manuscript in the Bodleian Library at Oxford, we must be allowed to doubt of the great talent in this way ascribed to him by his monkish biographers.

Some time after the conquest, a new species of engraving was introduced into England, in every respect different from the work of the chaser or carver, namely,
in engraving brass plates on the tomb-stones in churches. They were executed entirely with the graver, the outlines being first made out, and the shadows produced by strokes crossing each other, and cut deeper according to the strength of shadow intended, precisely in the way that copperplate engraving is executed at this time. Being usually laid flat on the stones to which they belonged, they formed part of the pavement of the church; and so being exposed to the feet of the congregation passing over them, they were necessarily executed in a coarse manner, and the strokes very deeply cut into the metal. There are some of these that often display very considerable talent in the artist.

The art of engraving seals on precious stones or gems, which was practised by the ancients, and carried by them to the greatest perfection, was probably the invention of the Egyptians; but of the means that were used to carve such hard substances, from the stupendous hieroglyphics which are seen at the temple of Tentyra, and other places, down to the numerous minute gems which formed personal ornaments, rings, signets, &c., we dare hardly hazard a conjecture. It is supposed that the cornuith stone, or adamanthine spar, was the substance employed for the purpose by the Egyptians Lapidaries, and Pliny informs us, that the Romans used to import sand from Ethiopia and India for this purpose, which it is probable was no other than the grit or powder of the cornuith stone. The earliest gem engravings of the Egyptians are in intaglio, consisting most commonly of a grasshopper, a scabbee, or an ibis, and in all probability executed before the invention of letters.

The earliest Greek engravings are likewise scarabees, and, in point of drawing, little superior to the Egyptian hieroglyphics, and strongly attest their origin: they are only distinguished from them by the addition of the names on the several gems, inscribed in the early Greek character. The art of gem engraving kept pace with Greece with the progress of sculpture; and by the time of Alexander the Great, it had arrived at the greatest perfection. While it declined under the successors of Alexander, it migrated to Sicily and Etruria, and there shone in undiminished splendour; but at Rome it never attained to any excellence, except in the hands of Greek artists. During the middle ages it was lost with the other arts, and was afterwards revived in the fifteenth century by John of Florence, and after him kept up by Dominic of Milan; but it has never in modern times regained its ancient perfection.

We have thus given a slight sketch of the art of engraving in the various ways in which it was practised by the ancients: it now remains to consider its origin and progress among the moderns, in its more important application of delivering impressions upon paper, from plates of metal and blocks of wood, by means of the printing or rolling press.

The honour of this invention is equally claimed by the Germans, Italians, and Dutch; but as the pretensions of the latter are by no means supported by any satisfactory evidence, they are not entitled to our consideration.

The art seems to have originated in Germany, in the brieft malers, or makers of playing cards, who cut their figures on blocks of wood, stamped them on paper, and at first coloured or illuminated them with the hand; but afterwards performed the operation in a much more expeditious manner, by blocks cut for the purpose, each colour requiring a separate stamp. The carvers of the blocks were called formschneider, i.e., cutters of forms.

As the mania for the adoration of images of the saints was, at this time, (the beginning of the 15th century,) carried to a most extravagant height, it occurred to the brief malers, that the public superstition might be made a source of considerable emolument to themselves. This led them to the cutting of images, and the representations of pious subjects, which were cut and illuminated like the cards, and illustrated with a title of the subject, or appropriate passages from legends, executed on the same block, in the Gothic characters then in use; these were vended for the edification and amusement of the unlettered, and those to whom written books were not accessible.

Baron Heineken discovered, "in the Carthusian monastery, at Buxheim, near Memmingen, a print of St. Christopher carrying the infant Jesus over the sea; opposite him is a hermit lighting him with his lantern; and behind him is a peasant, with a sack on his back, climbing to the top of a hill." This piece is of folio size, engraved on wood, and illuminated in the same way as playing cards, accompanied with an inscription at the bottom: Ecce vir eth, vir ecce trium felicis. Facillima sunt锥et ordine, "This curious print was found pasted on the inside of the cover of an old book; and there being no reason to doubt its authenticity, it proves that this method of engraving and printing was practised as early as the year 1423. This print was purchased by Earl Spencer some years ago, and is now in his possession. M. Heineken likewise informs us that, in the convents in Franconia, Swabia, Bavaria, and the Austrian countries, he found many early specimens of works of the same sort, which had been intended for the laity, and had been preserved by the monks, by attaching them to the inside of books.

These detached plates were soon followed by whole series, consisting of many plates, mostly in folio, printed under the name of legends, in which the figures of the saints differ little from each other, or from their prototypes, the figures on the cards. They are illuminated in like manner, and leave no doubt by whom they were executed, and are sometimes accompanied with passages of considerable length.

Amidst the books of images without text, there are Poor Man's Bibles. These were preserved in the libraries of the curious, several copies of the Historia vetere in Novi Testamenti, called also the Poor Man's Bible. Each plate contains appropriate sentences, or the names of the persons, sometimes at the top, sometimes at the bottom, or in scrolls in the middle, all in Latin. At the top and bottom are the busts of two saints, or prophets, with their names under them. In the middle are three historical subjects, that in the centre a principal one, and on each side one typical of it. We shall describe the first plate of this series, which will afford a fair specimen of the whole: it has the announcement in the centre; the inscription above is Ecce Virgo concebiet et pariet filium; on the one side are Eve and the serpent; and below, vix iram perdit, sine vi pariete puella; and farther down, on a scroll, porta hac clausa est, et non aperietur. In like manner, on the other side, is Gideon with his fleece; above, on a scroll, descendet dominus, sicut pluvia in vellum; below, rore madet Vellus, pluviam sitit arida tellus; lower down, creavit dominus; and, at the bottom, the indication of the principal subject, Virgo Salutator, innupta manens gravidatur. This work contains about 50 plates. There
is likewise an edition of this work, with plates somewhat different, with the inscriptions translated into the German language. There still exist copies of other similar works, such as Historia seu providentia Virginis Mariae ex Cantico Canticorum, and Historia Beatae Mariae Virginis, ex evangelistia et Patribus excrepta et per figuram illustrata. These led to books of text, illustrated with images, and engraved on one block, and in all probability the work of the brief maler, but printed only on one side of the paper; but in some examples the leaves are pasted together two and two, to look as if printed on both sides.

In these works of the brief malers, we see the origin both of prints and books. But though they practised this art for a long time, the important uses to which their invention might be extended did not occur to them, till, about the year 1442, Guttenberg of Strasburg, a man of a bold and speculative disposition, seeing these works, imagined, that, by cutting each letter separately, he would be able to print whatever he chose; in this, however, he was not successful, till, after incredible labour and expence, in conjunction with Faust, he found means to form them of metal, with punches and matrices, and produced, about the year 1450, an art edition of the Bible, the first book ever printed with moveable types, which, for beauty of execution, even at the present advanced state of the art, excites the wonder and astonishment of all who have seen it.

The art of engraving on wood began by degrees to assume a higher character. William Playdenwurf and Michael Wolgemuth are the first engravers on wood, whose names are preserved. They executed conjunctly, the plates of the Nuremburg Chronicle, which was published in folio in the year 1493. They consist of figures of various sorts, views of towns, &c. ; they are cut with much boldness and spirit; and the characters of the heads are often well delineated. They are, however, marked with all the stiffness and inaccuracy of drawing, which characterise the works of the German artists of that time.

In the works of the brief malers we see nothing but rude outlines, in the lowest style of art, (if it be at all entitled to the appellation,) without any attempt at correctness of drawing, expression, or effect. The artists who followed, who seem to have been numerous, attempting to give their works a little more finish, by introducing shadow, and paying some attention to drawing, brought the art nearer to perfection than it had yet been; and the completion of it was ultimately effected by the genius of Albert Durer, who, as far as regards the executive part of it, brought it to a perfection which has hardly been equalled by any succeeding artist.

It does not appear that Playdenwurf ever engraved on copper; but as at this time, with the exception of him, it was the practice of the engravers to exercise both arts, we defer the few criticisms we mean to offer on their works, till we come to the history of copper-plate engraving; and accordingly, in bringing it down to our own times, we shall take occasional notice of those who have distinguished themselves in engraving on wood. In concluding this part of the subject, we may remark, that it has been practised at different periods, both by painters and engravers, in every country where the fine arts have been cultivated since their revival, principally in those imitations of drawings called chiar oscuro, (of which we shall presently take notice,) as well as in the engraving vignettes, decorations for books, and mathematical diagrams; for these purposes it is well calculated, as the block can be inserted along with the text, and printed at the same time. This application of the art has been brought to the greatest perfection by Mr Bewick of Newcastle, who, in his two works, the history of birds and of quadrupeds, at the head of each article, has given a representation of the animal of which it treats, in a style which, for tastefulness of design, beauty, and delicacy of execution, have never been equalled, and their value is still further enhanced by their truth of representation.

Engraving in chiar oscuro is a method ofimitating slight drawings, by means of different blocks of wood.

The Italians ascribe the invention of this branch of the art to Ugo da Carpi, a painter and engraver, born at Rome about the year 1480; but as we have many specimens of chiar oscuro by the German masters, of a date much anterior to the time assigned by the Italians of its invention by Ugo da Carpi, particularly by Mann, dated 1490, and one by Lucas Cranach, 1500, we cannot admit that he was the inventor. In justice, however, to the claims of Ugo, it must be allowed, that the methods employed by the German artists differed materially from his. The former made out the outline and deep shadows by engraving them on copper, and then laid a middle tint over the whole by impression from a block of wood, cutting out the places where the clear light was intended to be left; while that of Ugo was performed entirely by different blocks of wood, one for the outline and dark shadows, another for the lighter shadows, and a third for the middle tint. Although the number of blocks was generally three, yet, in some instances, four and even five were used. Papillon (Histoire de la Gravure en Bois) gives a specimen of the process, consisting of four blocks, an impression of each of which is given separately, as well as one of them all in conjunction. It will be found at the 154th page of the second volume, to which we refer the curious reader.

The art of engraving on plates of metal, for taking impressions on paper, seems first to have been practised by the German goldsmiths, whose profession was at that time intimately connected with the arts of painting and sculpture. The finest specimens of which we have with dates, are those mentioned by Professor Christ, (Dictionnaire des Monogrammes,) one 1466, others 1466, and 1167. These are all without names, and the works of the several artists being only distinguished from each other by monograms, and logographies or enigmatical symbols, (which has occasioned much obscurity and confusion,) their names are totally unknown to us; but there are many other prints without either date or monogram, which, both from their design and execution, prove the existence of the art at a much earlier period.

The first artist whose name we are acquainted with, is Martin Schoen, a painter, engraver, and goldsmith. He was born at Culumbach in the year 1420, and died at Colmar 1486. His plates were executed between the years 1460 and 1485. They are very numerous, and, making the necessary allowance for the age and country in which he lived, and the disadvantages he laboured under, he must be allowed to be a man of strong mind and fertile imagination; though his figures have all the meagre taste and bad drawing of that time, his heads are well conceived, and the whole is executed with much mechanical skill. The taste of his design shows the influence of that branch of the art, yet the beauty of his execution displays a more advanced state in the mechanical part of the art of engraving. He is said to have been a pupil of Stoltzbeh, (an artist of whom we have no well authenticated work,) according to others, of Francis Stoss, to whose style that of Schoen bears a great re-
In engraving, semblance, though it must be allowed it is greatly improved.

If we admit that Schoen's preceptor, whoever he was, practised the art ten years before him, it places its origin as far back as the year 1460, ten years before the time fixed by Vasari for its Italian origin.

On the authority of Vasari, the Italians ascribe the invention to Maso, or Thomasso Finiguerra, about the year 1460; and this may be correct with regard to Italy: for it is very possible, that the art of engraving might have been practised long in Germany without the Italians being acquainted with it, as, except between Venice and Antwerp, there was at that time little intercourse between the two countries. It is, however, remarkable, that no sufficiently authenticated print of Finiguerra has ever been produced, although Mariette of Paris, and others, have made diligent inquiry on the subject. It is, however, probable, that amongst the old anonymous scraps of foliation and grotesque ornaments, undoubtedly the work of Italian goldsmiths, there may be some productions of this artist. There likewise remain two small pieces of this sort marked with a monogram, consisting of the letters M. F. somewhat similar to one of those used by Marc Antonio Raimondi, but the execution of the plate is in a very different style. This has been by some presumed to signify Maso Finiguerra; but it must be considered only as conjecture.

Sweynheym and Bucckink.

It is remarkable, that the first book printed at Rome, which also contained the first engravings executed there, (which were only maps,) was begun by Sweynheym, and on his death finished by Bucckink, both Germans, as the dedication to Pope Sixtus IV. indicates: "Magister Conradus Sweynheym, Germanus, a quo formandum Romanum librum ars primitiva precepta est, ... mathematicis adhibitis viris, quemadmodum talibus densis imprime- rentur edocuit," and that on his death, "Arnoldus Bucckink, Germanus, ad perfec- tum opus suum succedit." This work is dated 1478, but it appears that it had been begun as early as 1472. The plates are executed with great labour, and the letters are struck with punches by the blows of a hammer. From this it appears, that if Finiguerra did invent the art of engraving in 1460, it was kept a profound secret for eighteen years afterwards.

Baccio Baldini.

The next book that appeared in Italy with plates, was a copy of Dante's Inferno, published at Florence by Niccolo Lorenzo della Magna, in 1481, embellished with thirteen engravings by Baccio Baldini, from the designs of Alessandro Boccielle. Fac similes of two of these will be found in M. Heincken's work; and although the design of the figures is more pure and simple than that of their German contemporaries, and the engravings are executed with tolerable care, yet the style of execution is puerile and awkward, without any of the delicate finishing which characterises the works of the Germans even of that early period, and is another strong presumption of the justice of the claims of the latter to the invention of the art.

In tracing the history of the art, we cannot withhold from the Germans the precedence to which they seem justly entitled. We shall accordingly begin with the masters of that school.

Of Martin Schoen, and his predecessors, we have already made mention. The works of his brother Bartholomew, bear a strong resemblance to those of Martin, but without his neatness or expression. After them came Israel van Mechem, Phuydenwerp, Wolgemuth, and Mair, the inventor of chiar oscuro engraving.

But Albert Durer was the first that attempted to re-form the taste of his country, from the rude and barbarous style that was then practised. He displays a fertile imagination, and a preciseness of design, but without grace; and, with regard to his execution, if we do not discover in his plates the boldness and freedom which are desirable in large historical works, they at least display every thing requisite for subjects more minute and finished. Although the art of engraving has since had the advantage of the experience of three centuries, it would be difficult to find a more perfect specimen of executive excellence than his print of St. Jerome, engraved in the year 1514. He is supposed to have been the inventor of the art of etching: his works executed in that way are the earliest extant; they are not equal to his engravings, but his wood cuts are free and masterly. Although he was acquainted with the anatomy of the human figure, and designed it occasionally with correctness, his contours are neither graceful nor pleasing; and his figures and drapery are never entirely divested of the formal Gothic taste prevalent at that time. His plates are numerous, and much esteemed.

What we have said of the style of Albert Durer, applies in general to his pupil Aldegrever, Hans Sebald Beham, and his brother Bartholomew, Altdorfer, Binck, Goerting, George Penz, and Virgilius Solis, who, from the small size of the greater number of their plates, are generally distinguished by the name of the "little masters," although they have likewise executed large ones. Hans Holbin, a native of Augsburg, or, according to some, of Basle, an eminent painter, executed several engravings on wood. The most remarkable, are those called "the Dance of Death," consisting of fifty-three small prints, the first publication of which took place about the year 1530.

The German school long continued to produce engravings both on copper and wood, principally illustrations of books; but as from this period, it does not seem to have possessed any artists, whose works deserve particular consideration, and as the characteristics which distinguished it begin to disappear, from the artists going to Rome for the sake of improvement, we shall not prosecute the subject further, but proceed to the Italian school, from whence every thing that is great and excellent in modern art has emanated. Generally speaking, they drew correctly, but they seem to have been more anxious for ornament than fame, if we may judge from the prodigious number of Bible cuts, and religious subjects, executed by them, which have all the appearance of having been done with great rapidity.

After Boticelli and Baldini, already mentioned, Andrea Mantegna, and Antonio Pollajuolo, practised the school. Mantegna, by his superior knowledge of design, contributed more to its perfection than all his contemporaries in the style of his engraving. He has a great resemblance to Pollajuolo; but in the drawing of his figures he greatly surpasses him, particularly in the naked. Their plates are generally executed with single strokes, in a diagonal direction, without hatching or cross lines; in the manner of drawings done with a pen. Giovanni Maria di Brescia, and others, followed the manner of Mantegna, without however making any improvement in the art. But Beccabumi, without much neatness in handling, produced several works, both etched, and with the graver only, which display the talents of a great master. We have likewise by him, as well as by Andrea Andreani, many prints in chiar oscuro, a branch of the art which they carried to greater perfection than it had reached before them. The drawing is correct, and the execution neat and spirited.
The appearance of Marc Antonio forms the most brilliant epoch in the history of Italian art. He was born at Bologna about the year 1486, and there commenced his studies as a painter under the tuition of Raibolini, an artist of considerable celebrity at that time. In these he appears to have made great progress. It is not known with whom he learnt the art of engraving, but it is probable that it was from some one of the goldsmiths of that day. His first engravings are the four heroes, and his Pyramus and Thisbe, dated 1502, taken from the designs of Raibolini.

Being desirous of improving himself by travelling, he went to Venice, where he first saw the works of the German engravers, particularly a set of woodcuts by Albert Durer, representing the life and passion of Christ. These he copied with such accuracy on copper, that they were often sold for the originals; which coming to the knowledge of Albert, he came to Venice, and instituted a prosecution against him for the piracy before the senate.

The excellence of Roman design, which, by the genius of Michael Angelo and Raffaele, aided by the disinterment of the chef d'oeuvres of ancient art, and the magnificence of the Medici, had now reached its acme, attracted Marc Antonio to Rome, where his merit soon recommended him to the notice and friendship of Raffaele, who employed him to engrave from his designs under his own eye, and is said (though without sufficient evidence,) to have assisted him in correcting the outlines on his plates. The first plate which he executed from the design of Raffaele, was Lucretia stabbing herself; and in it he seems to have exerted all his abilities to make it neat and delicate: and soon after, the plate of the judgment of Paris; a work possessed of much more spirit and freedom. His engravings after Raffaele are very numerous, and are all marked with that correctness of scientific delineation, and beauty of character in his heads, which distinguish his works, and which place him, in this respect, in the highest rank of engravers of any age or nation.

The style of Marc Antonio, however, possesses none of the blanimishments of smooth delicate execution, to which his German contemporaries had attained in so eminent a degree. His manner is dry and unattractive, without any attempt at the representation of local colour, or the charms of chiar' oscuro, or reflected light.

Among the many young Italian artists whom the reputation of Marc Antonio had attracted to Rome, for the sake of his instruction, the following may be named; Agostino de' Musiis, Marc da Ravenna, Giuglio Bonasoni, Nicolo Beatrichi, and Enea Vico. His school was likewise frequented by several artists from Germany, such as Bartholomew Beham, George Peuz, James Binck, and many others.

Marc Antonio, during the lifetime of Raffaele, devoted himself almost exclusively to engraving the works of that master; but on his death, which happened in 1520, he executed several plates from the works of Giuglio Romano, and amongst others a set of lew subjects, accompanied with verses from the pen of the poet Aretino. This so highly offended Pope Clement VII. that he was cast into prison, from whence he was with great difficulty released at the intercession of Cardinal Giuglio de Medici and Baccio Bandinelli, the sculptor. In gratitude to the latter of these, he engraved, from a picture of his, the famous print of the martyrdom of St Lawrence; in which, the drawing of the naked (which he corrected) is excellent, the drapery is ample, and the character of the heads well expressed; qualities much greater than can be looked for from the reputation of Baccio Bandinelli. The last dated print we have of him is the battle of the Lapitha, 1539.

After Marc Antonio, the credit of Roman art was well maintained by his pupils, whom we have already mentioned, as well as by Georgio Ghisi, better known under the name of Mantuanus, his sister Diana, and their relations, Giovanni Battista and Adam Ghisi; though in none of the higher excellencies of the art has he ever been equalled by any of his successors. Agostino de' Musi introduced, in a few of his engravings, the method which has since been called Stippling. It had been occasionally practised as far back as Martin Schoen and Albert Durer; the latter of whom employed it imitating the texture of beaver hats, &c. Agostino perceiving that it was peculiarly expressive of softness and delicacy, executed flesh with it. A specimen of his method will be found among his works, in a small plate of an old man seated on a bench, with a cottage in the back ground; in this, the face of the figure is entirely stippled, or graver; but this occurs in his works only in one or two instances.

The art of engraving had been hitherto confined to small plates; but Cornelius Cort opened the way to a more important walk in the art. He was born at Hoorn, in Holland, in 1536. It is probable he was first instructed by Jerome Cocke; but after having engraved a considerable number of plates from the Dutch and Flemish painters, he went to Italy. He first settled at Venice, where he resided in the house of Titian, and engraved some of the finest works of that great painter. He afterwards established a school at Rome, where he executed those admirable works after Raffaele, and others of the Roman school, which are much sought after by the judicious collector. The plates of C. Cort are wrought entirely with the graver, in a bold, open, and masterly manner, and display more freedom of execution than had been attempted before. The drawing is correct and tasteful; and his back grounds, particularly his landscapes, are managed with great skill and address.

This style was imitated by Henry Golzius, who introduced it into the Low Countries, and laid the foundation of that great excellence which we admire so much in the works of Bolswert, Pontius, and Vos- terman. The beauty and characteristic beauties of the Roman and Florentine schools of painting were thus so successfully diffused by the talents of Marc Antonio, and his immediate successors, that the true era of the perfection of Italian engraving; for soon after this time, the capabilities of the art began to develop themselves, for displaying the charms of chiar' oscuro, the delicate trace of human flesh, and, to a certain extent, the beauties of local colour. Its professors gradually relaxed their efforts in the rugged and difficult paths of design, to follow the more flowery and attractive pursuits, which depend on freedom and dexterity of execution; but the higher excellencies of the art have never been entirely lost sight of by the Italian school, and they have shone forth with great splendour in our own times, united with all the beauties which the experience of so many centuries has so fully perfected, as the works of Cuneo and Volpato abundantly testify, and still more, those of Raffaele Morghen, and some of his pupils.

The art of engraving and etching was likewise cultivated with much success by most of the Italian painters. Titian etched many landscapes in a slight and spi-
The etchings of Stefano Della Bella, a pupil of Cantagallina, born at Florence 1610, are marked with the character of excellent taste. No artist has ever surpassed him in the delicacy and spirit with which he has handled the point; and his plates have a clear and brilliant effect. They are often slight, which is not surprising, when we consider that there are only about two or three hundred of them. His works are generally of a small size, and consist of every variety of subject—portraits, history, landscapes, and animals. Della Bella, who was also a pupil of Cantagallina, though born at Nancy in Lorraine, must be considered an artist of the Italian school. The fertility of invention, and the vast variety which are found in the works of this excellent artist, is truly astonishing. The talent he possessed of combining an amazing number of figures, and of varying their attitudes, without forced contrast, so that all, whether single figures or groups, may be distinguished from each other even in the shadows, was truly admirable, particularly when we consider the extreme minuteness of many of them. He generally (especially in his large prints) raised the point of sight to a considerable height, in order to afford more ample room for his figures, and greater scope to his invention. In that charming print called The Punishments, the number of figures he has introduced is astonishing; all of them disposed in different groups with the greatest judgment; and the actions of even the smallest of them, in the distance, are conspicuous, though the largest figure on the foreground scarcely exceeds three-fourths of an inch. The same may be said of his Fair, and many others. The subjects which Callot and Della Bella chose for their works, are nearly similar; but the excellence of the former consists in the clearness and perspicuity of his designs, the arrangement of his groups, and the firmness of his outline, while that of the latter consists in the freedom of his point, and the lightness and elegance of his figures.

The etchings of Spagnoletto (born 1580) are bold and free; his lights are broad and clear, and have a powerful and pleasing effect. He drew correctly, and the extremities of his figures are marked in a masterly manner. The characters of his heads are admirably expressed, particularly of his old men, which he was fond of introducing into his compositions. Guercino, (born 1590,) as an engraver, has left only two memorials behind him of his talents, a St John and a St Antony of Padua. They are executed with much spirit and freedom, in a style resembling his admirable drawings with a pen, which have been imitated so poorly by Pascualanges, and in our own time by Bartolozzi in a very superior style, from drawings in the collection of his present Majesty. Salvador Rosa has left many etchings, both history and landscape. In these we must not look for the grace and interesting delicacy of Correggio or Guido, nor the scientific design of the schools of Rome and Florence. His figures in general represent banditti; and his landscape, the wild and savage grandeur of Alpine scenery. His style is slight but masterly; his heads are admirable, but the limbs and other parts of the naked are incorrectly drawn. His draperies are stiff, and ill cast, and the whole destitute of elegance; however, the masses of light are finely preserved; and his landscape is sublime.

In the department of landscape, Claude Lorraine first claims our notice. He has left about 20 landscapes, though in general in rather a slovenly style of execution. They display great intelligence of the chiaroscuro, and have, to the eye of the judicious critic, an admirable effect. One of the most characteristic excellencies of his pictures, is the beauty, grace, and fine diversity of character in his trees; and these qualities he has transferred into his etchings with unparalleled success. One of these landscapes, in particular, may be mentioned, on the right side of which, in the middle ground, is a group of trees, and seen through the opening the ruins of an ancient temple, in which the richness and diversity of character, and the truth of nature, we hesitate not to say, have never been equalled. His subjects are the same as he represented on his canvass, landscapes with ancient ruins, rivers, and sea views, embellished with shipping, figures, and cattle. The etchings of his pupil Swanseveldt, which are very numerous, are executed with much spirit and effect. They are in general not at all composed, but though they possess much of the truth of nature, and great neatness of finish, they bear no comparison with those of Claude.

There are many beautiful etchings of the Italian landscape painters, as well as by French and other foreigners, who, studying in Italy, or forming their style on the Italian models, must be considered as belonging to that school, such as Gaspar Poussin, Milé, Glau-ber, Both, Rousseau, Sebastian Bourdon, Meyering, &c. But as the peculiarities of each will be better understood by an inspection of their works, than by any verbal description, we shall not enter on any further details on the subject.
ENGRAVING.

The first French engraver that we have on record, is Noël Garnier, who lived about the middle of the 16th century. His manner is very Gothic, and appears like the work of a goldsmith. He executed a great number of initial letters for books, ornamented with figures and foliage. After him flourished Stephen de Launne; his works are very numerous. They are in general small. He copied many of the prints of Marc Antonio with much success; but his engravings are mostly from his own designs. They are executed with the graver only, and have great merit. Claude Mellan introduced a new method. He expressed all the varieties of shadow by parallel lines without crossings, the greatest depth being given by only strengthening the lines, and consequently bringing them closer to each other; and the effect he produced is clear, soft, and agreeable. The number of his plates is very considerable, among which there are many admirable portraits. The most singular of all his productions is a print called the Holy Handkerchief, or Sudarium of St Veronica, executed with one spiral line, running in concentric circles from the point of the nose to the extremity of the work, with the motto, "formatur unicus una," representing, as large as life, the head of Christ, crowned with thorns, on a piece of linen. This print is not remarkable for any excellence of character or design; we adduce it solely as a specimen of his dexterity in the use of the graver, and the whimsical use to which he has here made of it. He died at Paris in 1688. But the most brilliant epoch of French engraving was the time of Louis XIV, when the magnificence of the monarch, aided by the taste of his minister Colbert, produced such a constellation of artists as had never before appeared at one time. The most distinguished of all these were Gerard Audelinck, and Gerard Audran. Thoughtformer was born at Antwerp, he must be considered as belonging to the French school, as the splendid works on which his fame rested were all executed at Paris, where he settled. This extraordinary artist wrought entirely with the graver; and his execution, which is both spirited and finished, discloses neither labour nor littleness, negligence nor mediocrity; and his heads are distinguished by the most lively expression. He was an accomplished master of what is called colour in engraving. He excelled both in history and portrait; many of his plates are of a large size, and very numerous, evincing a most surprising facility. Of the family of the Audrans there were six eminent engravers; but the most conspicuous is Gerard, born at Lyons in 1640. He carried the art to the highest pitch of perfection, particularly in his large plates of historical subjects. The immense plates of the battles of Alexander, after Le Brun, and his works after N. Poussin, and other Italian masters, are a lasting monument of his talents. The other artists of his family were all men of talents; and though none of them equalled Gerard, the numerous works they have left are an honour to their country.

Nanteuil, who applied himself exclusively to the engraving of portraits, certainly of all his contemporaries is entitled to the highest rank; and his works are considered as the first productions of that department of the art. His style, in clearness and beauty of effect, have never been surpassed. Although he died at the age of 49, the number of his plates is very great; all of them in a most finished style. In this department, the Drovers likewise hold a distinguished situation. There were three of this name. Peter Drevet the younger, is the most eminent of the family. His works are executed with the graver; though they have been surpassed in boldness and freedom, they have rarely been equalled in the beauty of his finishing, and the clearness of his stroke. His celebrated portraits of Bossuet and Samuel Bernard, are considered the finest specimens of that style of engraving. The style of Leclerc is different from all the preceding. The versatility of his talents is only equalled by the industry and success with which he exerted them. Besides his historical subjects and portraits of a large size, he executed an incredible number of small pieces of temporary interest, such as processions, triumphs, as well as architecture, landscapes, perspectives, and medals. In his best prints, the forms of his figures are elegant and correct; their draperies simple and well adapted to them, and the expression of his heads noble and characteristic; and the landscapes, buildings, and other accessories, are executed with great taste. He generally advanced his plates with the point, to a state which left the graver only to give them more harmony and depth of effect; and if his execution is inferior to Della Bella in the playful charm of the point, it possesses a judicious firmness, suited to the higher subjects he has engraved. The number of his plates amounts to nearly 5000.

There were many other artists of eminence at this time, such as Chereau, Cochin, Simonneau, Beuvain, Dupuis, &c., but of these our limits do not permit us to give any particular details.

Balechou, born 1715, carried the handling the graver, as far as relates to the clearness of the strokes and brilliancy of colour, to a greater perfection, than any preceding artist of his country; but notwithstanding the beauty of his execution, his flesh is like marble, and his drawing is lame and incorrect. These defects appear most conspicuous in his historical subjects and portraits; but his three landscapes, after Vernet, are amongst the finest productions of the graver.

Wille, a native of Germany, but who resided mostly at Paris, and flourished about 1760, carried the excellencies, which we have ascribed to Balechou, still further. No engraver, since his time, has ever equalled him in the clearness of his cutting, and the beauty and smoothness of his effect; and his style was admirably adapted to the subjects he chose, which were in general the conversations, and other familiar subjects of the Dutch and Flemish painters. He imitated satin with astonishing success. His print of the death of Cleopatra, after Netscher, affords a wonderful example of this. She is habited in white satin, and though we must condemn the taste which dictated such a costume in such a subject, very one must admire the talents which its execution displays. The flesh in this, as well
as most of his other works, is hard, and like marble, from the excessive clearness of his lines.

The landscapes, cattle pieces, and drolls of the Flemish and Dutch schools, have been rendered with much fidelity and spirit by Le Bas. He availed himself much of the freedom and facility of etching, which he harmonized in an admirable manner with the dry point and the graver. He executed upwards of an hundred plates after Teniers, besides numerous engravings from Ostade, Wouvermans, du Jardin, Berghem, and others of that school.

From the brilliant era of the age of Louis XIV. to the present time, the French school has distinguished itself for all the mechanical excellencies of the graver; but it is to be regretted that these qualities, after the time of Edelinck and the Audrants till within these few years, have seldom been displayed on subjects of legitimate historical composition, but have in general been confined to the representation of the most absurd and ridiculous frivolities. The genius of David, and a concurrence of other circumstances, have revived the study of the antique, and effected a total revolution in the national taste; but in leaving the one extreme of folly and affectation, they have gone to the other, that of cold insipidity. Their historical subjects now, in aiming at the chaste and rigid style of the antique, present nothing but groups of statues, without life, energy, or action, to those of Albert Durer. He is allowed to have surpassed Albert in composition, though inferior to him in design. His drawing of the figure is stiffly taken from the model, without grace or elegance in the style, which was at that time prevalent in his country. His execution is neat and clear; but as his stroke is equally fine in the fore-grounds as in the distances, and as there is a want of connection in the masses, his plates, though extremely neat, are inferior in firmness, harmony, and effect, to those of Albert Durer. He engraved on wood as well as copper, but his cuts are not numerous. They are spirited and masterly.

After the death of Lucas Van Leyden, the art seemed to have made little progress for many years, as the engravers seem to have been principally employed, as in Germany, in decorations for books. The Weirinxes, who flourished about 1580, and who imitated the style of Albert Durer, with the exception of correct drawing, and much attention to the marking out the extremities of their figures, did little towards its advancement.

The family of the Sadelers, at Brussels, made at this time a conspicuous figure. They drew correctly. Their earlier works have much of the German taste; but this they in a great measure laid aside when they visited Italy; we speak here more particularly of John and the elder Raphael Sadeler, as the younger branches, Giles or Regidius, Justus, and the younger Raphael, had the benefit of the instructions of their uncles. Their works are multifarious, consisting of history, landscape, and portraits; the latter of which are in general very fine, and much esteemed. There were in the Low Countries at this time many other artists, whose works display great talent; the elder and younger Peter de Jode, Philip, Theodore, and Cornelius Galle the elder, who all drew correctly; but as with them engraving was more an article of commerce than an art which was to be cultivated and improved for its own sake, it received little advantage from their exertions. Cornelius Bloemaert introduced a new style, which was the source from which the great engravers of the French school derived the principles of giving so much colour and harmony to their works. He tinted the lights on his distances, and other parts of his plates, with great care, which, till his time, had been uniformly left entirely untouched. By this improvement, he laid the foundation of those principles of colour and chiar' osuro, which form so essential a requisite to breadth and unity of effect, and have in later times been practised with so much success. The art received another important improvement from Henry Goltzius, who, on his return from studying at Rome, despising the neat and stiff manner of the little masters, introduced the bold, free, and clear style of cutting, which distinguish his works. He possessed a most profound knowledge of the figure, and drew correctly; but, in avoiding the formal style of his countrymen, and endeavouring to imitate the nobility of Michael Angelo, he, as well as Spranger, fell into the opposite extreme of bombastic absurdity and extravagance. However, he has never been surpassed, and hardly ever equalled in the freedom and dexterity of handling the graver. He engraved small portraits with much taste, neatness, and good drawing. He also cut, from his own designs, many blocks in chiar' osuro, in which he was very successful. The outlines are executed with all the freedom and dexterity for which he is so remarkable; and the works which he has produced in this way are truly excellent. He was followed by his disciples John Muller and Lucas Killian, who carried his style to a greater pitch of extravagance than his preceptor had done. But it was imitated with more judgment by Mathen and Sacredam, whose works display more delicacy and correctness.

The brilliancy and splendour of Rubens afforded a new object for the imitation of the engraver, for which the improvements of Corn. Bloemaert and Goltzius had prepared the way. About the beginning of the seventeenth century, flourished the two Bolswerts, whose first exercises were in the style of Goltzius; but under the instruction of Rubens, they improved their style. Of this school, Paul Pontius, Vosterman, the younger Peter de Jode, and others, make a distinguished figure, principally in their engravings after Rubens and Van Dyke. They all drew correctly, and have been very successful in rendering the harmony and beauty of the originals. But after the death of Rubens, the art of engraving gradually declined, and ceased to produce, in the higher department of the art, any specimens worthy of our attention. But in the departments of landscape and animals, and such subjects, in which the Dutch and Flemish schools excelled, there are many beautiful etchings, executed principally by the painters. In considering this part of our subject, we cannot withhold from Rembrandt the pre-eminence to which his Rembrandt works so justly entitle him; they consist of history, landscape, and portraits. His drawing of the human figure is very bad; his heads are all of a low and vul-
ENGRAVING.

The family of the Visschers displayed great excellence in the art. They all drew with great taste; and, both in their compositions and engravings from other masters, showed genius and science in an eminent degree. Cornelius Visscher stands unrivalled for the fidelity and spirit wherewith he has rendered the character and effect of the pictures he worked from; and is justly considered an excellent model of imitation for all young engravers. His etchings are free and spirited; but his works with the graver are admirable. His mode of execution with that instrument was as singular as the effect he produced was scientific and beautiful; his strokes on the draperies and backgrounds, are laid, as it would appear, without attention or study; in what direction they should lie, but just as the plate happened to lie before him, and these he crossed and recrossed till he had produced the necessary depth of shadow or colour; but on the flesh he bestowed particular care, and his heads are finished in an excellent style, and display both the character and expression of the original, and his dexterity in handling the graver. He has left many works of considerable size, both from his own designs, and the pictures of the Italian and Flemish masters, history, portrait, conversations, and landscapes, &c. which are much esteemed. His brother, John Visscher, was likewise an excellent artist. His works are principally etchings from Berghem, Du Jardin, Ostade, and Brouwer. His effect is beautiful and harmonious; his drawing excellent, and his execution free and spirited. His principal works are after Berghem; in them he has rendered the spirit of the originals with much truth, and the animals are drawn with great beauty and spirit. Nicholas John Visscher, another of the same family, has left many etchings in a free, spirited, and masterly style. Though but slightly finished, his drawing is correct; but he paid little attention to colour or general effect, and left many parts of his plates untinted. His works, which are numerous, are principally landscapes, with small figures and cattle, from Berghem and Du Jardin.

The painters of the Dutch school have likewise produced many beautiful etchings of landscapes, conversations, cattle, &c. The landscapes of Waterloo are esteemed most. The subjects he chose were wood and rural scenery. They are executed with much freedom and great truth. They exhibit none of the taste, grace, or refined elegance of Claude Lorrain; but are evidently studies of individual nature, without much imagination, sentiment, or selection.

With the etchings of Waterloo, we may contrast the works, in this way, which have been left us by Jakob Ruysdael. Without the finishing of Waterloo, they possess infinitely more spirit and freedom. They are little more than outlines. His trees have much character and variety; and in decayed trunks, and similar objects on the foreground, in boldness and powerful execution, he is surpassed only by Rembrandt. The etchings of Ostade represent merry meetings, and similar subjects, conceived with great humour, and executed with much spirit; and the figures and still life admirably grouped. They are all from his own designs, of various sizes, and very numerous, and of different degrees of merit.

Of all the painters who have etched animals, for scientific drawing and profound anatomical knowledge, there is none to be compared to Paul Potter. He has left many etchings, wherein he has exerted his great talent in this way with much success. His figures are grouped with great taste, and their extremities are...
marked with great precision. His etchings are not very numerous, and sell at very high prices. Adrian Van de Veldt, and Karl du Jardin, have likewise executed many etchings of cattle, which, for tastefulness, correctness of design and anatomical knowledge, are next to those of Paul Potter; while those of Berghem, which are executed with the greatest spirit and taste, and are also well drawn, are, on a comparison with the works of those we have just mentioned, very deficient in the truth and beauty of anatomical detail. There are many etchings by Cuyp, Stoop, Bamboccio, and others, possessing in a greater or lesser degree the excellencies which we have mentioned; but on a consideration of these, our limits do not permit us to enter. We cannot, however, conclude this account of the Dutch school, without making respectfully mention of an amateur whose works display so much genius, and would do honour to any artist,—the person we allude to is Count Goudt of Utrecht. This extraordinary personage practised the art solely for his amusement; he flourished about the year 1610. The plates which he has left are seven in number, all from the pictures of Adam Elsheimer, with whom he had contracted an intimacy at Rome. His drawing is correct and tasteful; his heads are finely marked; the extremities are judiciously managed; the effect is strong, deep, and powerful; and the execution neat. The plates are all remarkable for some peculiar effect, of fire or moonlight, of the stillness of the morning, or the deep solemnity of twilight; and in them we know not which most to admire, the correctness of his design, the beauty of his effect, the fine sentiment he has so happily infused into his works, or the neatness and appropriate style of his execution. He wrought entirely with the graver, and produced his effect not in the usual manner, by strengthening the strokes, but by crossing five or six times in the deep shadows, with other strokes equally neat. His print called the Scenery, is certainly hard and harmonious, from the sudden transition of the strong lights into the deep shadows; but in the fine impressions, where the delicate tinting on the lights has not been worn away, this is not so conspicuous.

Till about the middle of the last century, the fine arts had been but little cultivated in England; and the works of any consequence that were executed, were in general the productions of foreigners, invited from the continent by the occasional munificence of the monarch, or the taste of a few of the nobility. Among the artists who have at different times visited England, there have been several eminent engravers, principally in the departments of history and portrait. The most distinguished of these are Simon and Crispin de Passe, Wallerant Vaillant, Judocus and Henry Hondius, Lucas Vosterman, Hollar, Blooteling, Vanderbank, Dorigny; but till the time of the elder Faithorne, who flourished in 1670, the native engravers limited themselves to maps, cuts, and small portraits for books, all of which are greatly below mediocrity.

John Payne, a scholar of Simon de Passe, is the first English engraver who merits our attention. He possessed great talents, as his works sufficiently testify; they are not numerous, as he led an irregular life, and died early. His chief works are frontispieces, and other book cuts and portraits; he also executed a variety of other subjects, landscapes, animals, flowers, fruit, birds, &c.; but several of his portraits are very fine, and by far the best of his works: these he executed entirely with the graver, in a free open style, and they have a pleasing effect. He likewise engraved a large print of a ship, called the Royal Sovereign, on two plates, which, when joined, were three feet long, by two feet two inches high. He died about the year 1648.

Faithorne is the next English engraver who merits our attention. He was a man of great genius, and being obliged to leave England during the civil war, he went to Paris, where he derived great advantage from the instructions of Nanteuil. And on his return to his native country, he executed a great number of portraits, and neutral historical subjects in an excellent manner: he worked almost entirely with the graver. In the early part of his life, he imitated the Dutch and Flemish manner of engraving; but on his return from France, he greatly improved it. His best portraits are admirable, and are finished in a free delicate style, with much force of colour; his drawing of the human figure is by no means correct nor in a good taste, but as he dedicated so much of his time to portrait, the few historical works he has left are not fair specimens of his talents. His portraits are numerous, and not of equal merit, his best ones are very valuable. His son William Faithorne engraved many portraits in mezzotinto, which are greatly inferior to the works of his father. The invention of this method of engraving, which a little before this was brought into England, and has been since cultivated with so much success, is generally attributed to Prince Rupert, who, it is said, one morning seeing a soldier cleaning his musket, which had been rusted by the night dew, and observing something of the appearance of a figure corroded on the barrel, he conceived the idea that, by covering the plate with such a grained ground, and scraping away the parts where the lights were required, he might produce the effect of a drawing; and that, having communicated his ideas on the subject to Wallerant Vaillant, with his assistance he invented an instrument, which, in some sort, answered this purpose. The Prince engraved in this way a print of an executioner, holding in one hand a sword, and in the other a head, after Spagmoldtto, dated 1648. He afterwards engraved, on a reduced scale, the head of the executioner, for Mr Evelyn's Sculptures, who therein assures us, that it was given to him as a specimen of the new invented art by Prince Rupert himself. But, on the other hand, it is positively asserted by Baron Heinken, whom we have so often quoted, that it was invented by Lieutenant Colonel Siegen, an officer in the service of the Landgrave of Hesse, and that the print which he produced was the portrait of Prince Amelia Elizabeth of Hesse, engraved as early as the year 1645, and that Prince Rupert learned the secret from him, and brought it to England, when he came over the second time with King Charles II.

Robert White, the scholar of Loggan, born 1645, be- sides many portraits in black lead on vellum, in which he was very successful, has left many engravings of portraits, frontispieces, and book decorations. His engravings, though respectable, are not equal to his drawings. He likewise engraved a few portraits in mezzotinto, which are much inferior to his other engravings.

His son George White, learned the principles of drawing and engraving from his father. His engravings are neatly executed, but his principal works are in mezzotinto, in which he was very successful. He frequently etched the outlines of his portrait before he laid on the mezzotinto ground, which gives him firmness and precision to his effect. The last portrait we have of him was Bishop Weston, 1731.
George Vertue, born 1684, a scholar of Michael Vandergucht, was one of the most industrious artists that this country has ever produced. He has left a numerous collection of portraits, many of them very respectable, many book cuts, Oxford almanacks, and antiquities of all kinds; and he made many drawings in water colours, with the view of engraving them. We are likewise greatly indebted to him for his Lives of the English Artists, a work for which he was indefatigable in collecting information, as well as in procuring portraits of the artists. The manuscript work came into the hands of the Hon. Horace Walpole, who revised and published it. It abounds in much curious and interesting information, and is well known. He died 1756.

We have several works executed with great spirit and taste, in a very artist-like manner, the productions of Arthur Pond and George Knapton; among others, a set of plates, in imitation of chalk, and washed drawings, from the designs of the great Italian masters: some of these are in chiar' oscuro, with etched outlines. They flourished about the year 1740.

The first artist of any school, who has been completely successful in rendering with the truth, spirit, and character of the originals, the landscapes of the great Italian masters, (not even excepting Edelinck and Audran, in their beautiful works in this way,) is Francis Vivares: he was a native of France. It appears that he did not apply himself to the arts till he was considerably advanced in life. He learned the principles of the art from Chatelin in London; but being a man of great genius, he improved on the style of his preceptor, and acquired such freedom in etching as had never been possessed before by any engraver: the foliage of his trees is delicately and lightly expressed; and his effect is deep, broad, and clear. His finest works are from the pictures of Claude Lorrain, and possess infinitely more of the character of the originals than those of any other engraver.

He must be considered as the founder of the English school of landscape engraving, and although (except by Woollett) he has never been equalled, the light which he gave to succeeding artists has been the means of keeping up that decided superiority in this department which this school possesses above every other. He brought his plates to a state of considerable finish and effect with the point, and put the last touches on them with the graver.

The landscapes of Woollett stand unrivalled for beauty of execution, and may be considered the most perfect models of style for landscape. Like Vivares, he carried his plates a considerable way with the point, and gave them the necessary depth with the graver, touching them up in the more delicate parts with the dry point. His works have all the delicacy and clearness of the French masters, and with all the spirit and taste of Vivares. He likewise executed several historical plates and portraits with great success. His chief works are the large landscapes, which he has engraved from R. Wilson, and others; the Death of General Wolfe, after West; and a small portrait of Rubens, after himself. In tracing the progress of this branch of the art, we cannot withhold our admiration from these two great men, who, from the state of total insignificance and neglect in which they found it, raised it at once to such dignity and perfection. The earliest landscapes we have of any importance from the works of the great painters, are the engravings of Bolswert, after the pictures of Rubens. They are executed with his usual ability, in the large broad style which distinguishes his historical works; but, being entirely with the graver, give a very inadequate idea of the character of the foliage, the quality of surface of the several objects, or the brilliancy and splendour of Rubens. The large set of landscapes by Audran, after Nicolo Poussin, exhibits a nearer approximation to the true style of landscape, than those of Bolswert, being executed in a style of much greater delicacy; but, from the unmanageable nature of the graver for such subjects, with which they are entirely executed, they are still very defective in character and spirit. The landscapes of Balechou, which are unrivelled for clean cutting and dexterity of handling the graver, display a most erroneous conception of the true object of art, and afford, notwithstanding their astonishing mechanical excellencies, very imperfect representations of the aerial nature of clouds, the liquidity of water, or the richness and variety of nature in the foliage of trees. The discrimination of Vivares and Woollett pointed out the defects of their predecessors; and, more particularly in the works of the latter, we find all the truth of nature united to all the beauties of mechanical skill.

John Browne is another eminent engraver of landscape of this time. He has executed several large works after S. Ross, Both, and other great masters, in an excellent style. He likewise etched many of the plates which were afterwards finished by Woollett with the graver.

From this period, the English school is prolific in artists in every department. In history, the first name that we ought to mention is that of Sir Robert Strange. He is admirable for the breadth of his effect, and the beauty of his execution; but his great excellency is the delicacy and softness of his female flesh. In this last, notwithstanding the perfection that modern art has arrived at, in all those great qualities which result from mechanical skill, he has never been equalled by any master, as his engravings from the works of Titian, Guido, Corregio, and the other painters of the Italian schools, sufficiently show; but it is deep to be regretted that, with so many excellencies, his drawing should be so incorrect, particularly in the extremities. Of the other artists who have excelled in history, we have only room to mention a few names: Legat, Basire, Hall, Ryland, Bartolozzi, Heath, Holloway, and many others of our cotemporaries, who maintain, with distinguished success, the respectability of English art.

In the engraving of portrait, the English school, for a century back, has produced little in the line manner, which in this way has been almost entirely superseded by mezzotinto; and, more particularly in small portraits, by stippling. The method of mezzotinto is admirably adapted for portraits, especially in the imitating of the bold, broad manner, of the English style, which originated in Sir Joshua Reynolds, and has ever since been the distinguishing characteristic of this school. We have many good portraits by the earlier artists, such as Faber, M‘Ardell, Smith, Williams, and others; but, in the portraits of Earlom, Watson, V. Green, &c. after Reynolds, we see the art carried to the utmost perfection. In stippling, or the chalk manner, the artists and their productions are innumerable, and of very different degrees of merit; principally of a small size for books. We have, however, many beautifully executed in the black manner, by Bartolozzi, Hall, Collyer, and others; but there is perhaps none superior to those of Caroline Watson, who has produced, among many others, that head of Sir J. Reynolds which forms the frontispiece to
his works, and which, for spirit and effect, is hardly surpassed by the works of any artist.

In landscape, besides Vivares, Woollett, and Brown, whom we have already mentioned, we have many fine works, principally from the pictures of the old masters, by Byrne, Mason, Wood, Elliott, Lowry, Wilson, Major, Earlm, and others; but, of late years, the taste for embellishing books with subjects of topography and antiquities, having been carried to a most extravagant height, has diverted the current of British genius from the more dignified province of heroic landscape, and absorbed all the talent of the English school; which, (without depreciating the true value and interest of such works), would have been more worthily employed in translating the works of Claude Lorraine, Poussin, R. Wilson, and some of the eminent artists of the English school.

Engraving in aquatinta, which was invented by Sti-Nou, and communicated to Le Prince of Paris about the middle of last century, was brought to England, and greatly improved by Sandby. It has been carried to great perfection by our contemporaries, in imitating Indian drawings; and the process, being simple and expeditious, and of course well adapted to commercial purposes, has been much practised. The English painters have produced few etchings that merit our attention; and what they have executed, are chiefly on the soft ground, or on stone, the separate processes of which will be found detailed at the end of this article.

Mezzotinto has been likewise employed with the greatest success in imitating the effect of drawings, as is exemplified in the excellent work by Earlem, called the Liber Veritatis, being a collection of 200 plates from the drawings of Claude Lorraine, in the collection of the Duke of Devonshire. The brilliancy of the effect has been rendered in an admirable style with the mezzotinto, and the outline added with much truth and spirit, with etching.

In the department of drolls and conversations, till the appearance of Wilkie, the English school never produced any thing; but, in the engravings of the Village Politicians by Raimbach, and the Blind Fiddler by our countryman Burnet, from the pictures of that master, we see specimens of British talent which rival the beautiful works of Le Bas after the pictures of Teniers.

The works of Hogarth exhibit a walk of art unprecedented before him. The Dutch and Flemish schools had carried the representation of local manners to great perfection; but Hogarth added to this a dramatic and didactic character, strong and poignant satire, and epigrammatic point. "I consider that great and original genius," says Lord Orford, "rather as a writer of comedy with a pencil, than a painter. If catching the manners and follies of an age, 'living as they rise,' if general satires on vices, familiarized by strokes of nature, and heightened by wit, and the whole maintained by proper and just expressions of the passions, be comedy, Hogarth composed comedy as much as Molieres. In his Marriage à la Mode, there is even an intrigue carried on through the whole piece. He is more true to character than Congreve; each personage is distinct from the rest, acts in his sphere, and cannot be confounded with any other of the dramatis personae. The alderman's footboy, in the last print of the set I have mentioned, is an ignorant rustic; and if wit is struck out of the characters in which it is not expected, it is from their acting conformably to their situation, and from the mode of their passions, not from their having the wit of fine gentlemen. Sometimes he rose to tragedy, not however in the catastrophe of kings and heroes, but in marking how vice conducts insensibly and incidentally to misery and shame. He warns against encouraging cruelty and idleness in young minds, and discerns how the different vices of the great and of the vulgar, lead, by different paths, to the same unhappy end. The fine lady in Marriage à la Mode, and Tom Nero in the Four Stages of Cruelty, terminate their story in blood; she occasions the murder of her husband; he assassinates his mistress. It is seldom that his figures do not express the character he intended to give them. When they wanted an illustration which colours could not bestow, collateral circumstances, full of wit, supply notes. The nobleman in Marriage à la Mode has a great air, and the coronet on his crutches, and his pedigree issuing from the bowels of William the Conqueror, add to his character. In the Breakfast Scene, the old steward reflects for the spectator. Sometimes a short label is an epigram, and is never introduced without improving the subject. His plates are numerous, and have all the expression and character of his pictures, and are executed with great boldness and spirit. His drawing, though not correct, is almost sufficient for the subjects which he excelled in. It is to be regretted, that his ambition prompted him, in an evil hour, to aspire to the rank of a historical painter—a walk of art in which, from his previous pursuits, and the peculiar nature of his talents, (great as they were), he was no more qualified to excel. He painted several pictures in this way, which display the greatest ignorance of the requisites essential to this branch of the art; and are completely destitute of good taste, correctness of design, colouring, in short of every quality which is considered indispensable in such subjects. He has likewise engraved them, and in a style which, though happily suited for those subjects on which his fame rests, have turned his history into caricature.

There are various kinds of engraving, as has already been seen; but that which is performed with the graver is the oldest, and to it, in common language, the term engraving is often exclusively applied, in contradistinction to etching, mezzotinto, or any other method.

The improvements of modern art have given a degree of importance to the etching-needle, which the older masters did not acknowledge: and, accordingly, works of every description, from the largest historical plates to the smallest vignettes, are, with it, brought up to considerable effect, and finished to the necessary depth with the graver; the lights on the more delicate parts being tinted with the dry point.

The principal instruments used in stroke engraving are, the graver or burin, of which there are various sorts; a scraper, a burnisher; and a cushion for supporting the instrument.

The graver is an instrument made of steel, of the form of a quadrangular prism, about one tenth of an inch thick, increasing a little in thickness as it approaches the handle, which is made of wood. In marking the incision, it is pushed forward by the hand in the direction of the line required, and held at an angle very slightly inclined to the plane of the copper. It is obvious, that it must be performed with only one (the lower) angle of the tool, and the point is formed by bevelling off the end of the instrument.
The burnisher is about three inches long, is used to soften any of the lines which are cut too deep, as well as in the preparation of the copper.

The scraper is an instrument of steel also, about six inches long, tapering to a point, having three sharp edges. It is used to scrape off the barb that is formed by the action of the graver. In order to show the appearance of the work as it goes on, and to polish off more completely the barb, a roll of felt or woollen cloth, called a rubber, is used for rubbing the part of the plate with a little olive oil.

A cushion, being a leather bag of sand, of about nine inches diameter, was formerly used to lay the plate upon, to allow it to be turned in any direction; but this is now never used, except by the engravers of writing.

For engraving a series of parallel lines, which are all either equidistant, or approximating towards each other in regular gradation, from a great to the most minute distance, such as in the blue part of a sky, water, or in plates of machinery, &c. where a smooth flat tint is required, an apparatus called the ruling-machine was some years ago invented by Mr Wilson Lowry of London. The accuracy of its operation is perfect, and the beauty of the execution is unequalled by any thing that has ever been performed in any other way. It is performed on the etching ground by a point or knife connected with the apparatus, so as to move with unravelling certainty, and bit up in the usual way with the aquafortis. This instrument will be elsewhere found minutely described: (See Ruling Machine). There are numberless specimens throughout this work of the productions of this machine, and we may mention at random, Plates CC and CCC, to which we refer the reader.

In wood engraving, the block is commonly made of pear-tree or box, and differs in thickness according to its size. The surface for the engraving is on the transverse section of the wood: the subject is drawn upon it with a pen and Indian ink, with all the finishing that it is required to have in the impression. The spaces between the lines are cut away, with knives, chisels, and gouges, leaving the lines that have been drawn with the ink.

It will be seen, from this, that the taking impressions from blocks of wood differs from that of copper-plate in this, that in the latter they are delivered from the incision, while in the wooden block they are delivered from the raised part.

In looking at the works of the old German artists, from the time of Albert Durer down to Christopher Jegher, we are surprised at the frequent occurrence and freedom of execution of the dark cross hatchings—an operation which, by the common process of cutting away the interstices, could not be done but with the greatest labour, and certainly without the freedom which those artists have displayed.

As many of the impressions exhibit unequivocal evidence of being worm-eaten, every doubt is removed of the nature of the material on which they have been wrought. We are therefore irresistibly led to the conclusion, that those parts, instead of being cut with the tool, have been executed by some chemical process, in some degree analogous to etching on copper, by corroding the interstices instead of the lines; and it has been suggested to us by an eminent artist of this city, Mr W. Lizar, that this might have been accomplished by sketching in the work with any bituminous substance capable of resisting the action of acid, such as the common etching-ground, (see Etching), rendered fluid by solution in oil of turpentine, put on with a pen or hair pencil, and the rest afterwards corroded.

We have likewise seen several works in this way, portraits and sketches of all sorts, executed by Mr D. Somerville, wherein he has introduced these crossings with the utmost freedom and delicacy. His method he does not choose at present to divulge, as he intends making it the subject of a publication.

The method of chiaroscuro engraving, the history of which we have already given, is performed with three blocks. The outline is cut in one, the deep shadows in a second, and the third gives a tint over the whole, except where the lights are cut away. See Paillon, Histoire de la Gravure en Bois.

Etching is performed by covering the plate entirely with a ground capable of resisting the action of aquafortis. The design is made with a black-lead pencil on a piece of paper of the same size, which being moistened for some time in water, and laid on the plate with its face next the etching-ground, and run through the rolling-press, leaves a distinct impression on it, which is partially transferred from the paper. The operation of the needle then takes place, which is performed by scratching with the point the lines in the different directions, and crossing them according to the effect required. The thickness of the lines, which is regulated by the quality and distance of the object, will be varied by the size of the point of the etching-needle, being greater or less according to the purpose for which it is intended. The corrosion with the nitric acid is performed by making a wall round the plate of what is called bordering wax, in order to contain the aquafortis, which is then poured over it, and allowed to remain on it according to the depth that the work may require. It may be then touched up with the dry point, or deepened, if necessary, with the graver, having previously cleaned off the ground with turpentine.

The etching with the dry point is performed on the plate, without any ground, solely by the point of the needle; and the barb which is raised by the operation is taken out by the scraper.

Etching with the soft ground is a method of making imitations of black-lead or chalk drawings. The ground is mixed with a proportion of tallow or hog's-lard, according to the state of the weather. A piece of thin paper is put over the plate, and attached to it by wax, or a pitch. The design is then made out on the paper, and shaded to the necessary degree of effect with the black-lead pencil, and the action of the pencil on the paper takes off the ground from the copper at the same time; and when finished, it is bit to the requisite depth in the usual way. The details of the various processes will be found more minutely detailed in the article Etching.

Stippling, or the chalk manner, is performed likewise on the etching ground, by dots instead of lines made with the etching needle; which are made closer and thicker, according to the depth of the shadow. A small wheel, consisting of many points diverging from its centre, and revolving on its centre, and fixed on a piece of steel wire inserted into a wooden handle, is sometimes used; by moving this backwards and forwards, the points mark the copper, and give an excellent imitation of the freedom of chalk-drawing. The work is then bit with the aquafortis in the usual way.

Another method of etching has just been discovered by Mr H. W. Williams, and Mr R. Stein of Edinburgh: it is performed by instruments totally different from the etching needle; the beauty and richness of its effect is only equalled by the rapidity with which it is executed. Although the inventors have not as yet proc-
Engraving.

Cut their discovery as far as it is obviously susceptible, yet what they have produced shows that it is capable of much variety of application. The specimens consist mostly of landscape and sea views; the skies, which are executed with minute parallel lines, have all the delicacy and smoothness of aquatinta; the water is perfectly liquid and transparent, and the rugged character of the rocks, and other objects in the foreground, is admirably expressed. The process they do not mean at present to communicate, but a volume of the specimens they will shortly publish.

Engraving on steel is principally employed for cutting signets, punches, matrices, and dies proper for striking coins and medals. The engraving of the device of the punches is performed in relief, according to a model in wax; and when finished, it receives a high temper, in order to stand the blows of the hammer in striking the matrix. The steel of the matrix is made hot to soften it, that it may more easily take the impression of the punch; and when struck, is touched up where there are any deficiencies, by means of graving tools, chisels, &c. The mouldings of the border, engraved ring, letters, &c. are then struck with small steel punches, well tempered, and very sharp.

Etching on steel is performed by drawing the design with Brunswick black, laid on with a hair pencil. It is then bedded in glazier's putty, or the bordering wax used for etching, and the aquafortis poured over it, and suffered to remain till it be bit to the requisite depth. It may then be poured off, and the black cleaned away with a little turpentine.

The method of mezzotinto engraving is by first laying a ground on the copper, by roughening the whole surface with a serrated or toothed instrument, and moved in various directions, till it be brought to such a state as to be capable, if an impression were taken from it in this stage of the process, of giving a flat black tint to the whole. The outline is then traced with an etching needle. The lightest parts are then scraped to the greatest smoothness; and the middle tints are also produced in the same manner, by scraping them, so as to leave a greater or less portion of the ground, according to the depth required.

Engraving on stone, is a method of imitating pen and ink drawings, for which the inventor some years ago obtained a patent. It is performed on a slab of marble, or some close-grained stone. The design and effect is made out, with a pen dipped in a solution of lac, in the ley of pure soda, with a little soap, and coloured with lamp black.

When the drawing has been on the stone for three or four days, or when the ink is perfectly dry, it is soaked in water. In this state it is daubed with printer's ink from the balls, and the ink will adhere to the design and not to the stone. The impression will be taken from it in the same way as letter-press printing, by putting a sheet of damp paper over it, and subjecting it to the action of the printing-press.

Another method of engraving or printing on stone was invented by Alois Senefelder, a native of Prague in Bohemia, who obtained an exclusive privilege for it from the Elector of Bavaria, in 1801; and, in 1803, a like privilege from the Emperor of Austria. He accordingly established stone printing-houses at Munich and Vienna; and, under his direction, similar establishments were formed in France and Italy; but it is at Munich that the art has been brought to the greatest perfection. It has been found well adapted for imitation of wood-cuts, drawings, music, all kinds of writing, and geographical maps.

The method is to take a calcareous stone or slab of marble, with a good polish, of from two to three inches thick, and of a size proportioned to that of the work to be executed on it. The design, notes, or letters, are marked out with a solution of gum lac and potash, coloured with lamp black. When they are dry, the stone is covered with aquafortis; and the acid attacking all parts of the stone except those which have been impregnated with the resinous ink, the drawing remains untouched, and appears like the block of a woodcut. When the acid has corroded to a sufficient depth, the slab is washed with clean water, and, while wet, printing ink is applied to it with balls in the usual way, and put through the rolling press. At each proof, the block must be washed with water. This method, for expedition, cheapness, and durability, has greatly the advantage over the usual processes, particularly for music; and it is said, that, at the stone printing office at Vienna, thirty thousand impressions were taken off the same slab, and the last impressions were nearly as good as the first.

Etching on glass is performed by laying on a ground consisting of a thin coat of bees-wax, and making out the design with an etching needle. It is then covered with sulphuric acid, and sprinkled over with pounded Derbyshire spar (fluor spar). It must be taken off after four or five hours; and when cleaned with oil of turpentine, the etching will appear, leaving what had been covered with the wax untouched. By this method, glass vessels are graduated, or ornamented.

This process is sometimes reversed, by putting on the design or ornament with a solution of bees-wax in turpentine, and exposing the ground to the action of the acid, which, when sufficiently corroded, will leave the ornament untouched, and the ground deprived of part of its polish and transparency. It is to be observed, that the sulphuric acid does not immediately act on the glass, but only by expelling one of the constituent parts of the spar, (the fluoric acid,) so that the effect of the corrosion will be according to the quantity of the fluoric acid evolved, acting on the glass; and as it possesses much greater activity in the gaseous state than when combined with water, the operation will be performed more expeditiously by exposing the plate to the action of the gas as it evolves, properly secured to prevent its escape; and in this way, several plates may be at once.

Seal-engraving, which is performed both in cameo and intaglio, was an art much practised by the ancients. It was performed on all sorts of precious stones, but onyx was the most commonly used for this purpose. The operation is performed by inserting the tools into the axis of a small iron wheel, which is attached to an apparatus like a turner's lathe, and kept in motion by the foot. The tools are tightened by a screw, and the stone to be engraved is applied by the hand to the tool as it revolves, and is shifted and conducted as required. The tools are generally of iron, and sometimes of brass; their forms are various, generally resembling chisels and gouges; some have small round heads like buttons, others flat, &c.; and when the stone has been engraved, it is polished on wheels of hair brushes and tripoli.

ENHARMONIC.

ENHARMONIC Change, in music, is the occasional substitution, during performance, of one interval for another, differing therefrom, in a slight degree, in order to avoid that departure from the original pitch, which is called DIVERGENCY of Tune, (see that article.) The Rev. Henry Liston, in his valuable work, entitled An Essay on perfect Intonation, p. 72, after giving an extract from Huygen's Cosmologie, remarks, that the pitch, in singing, or on his organ, &c. cannot be preserved by slightly tendering every interval, but must be effect by substituting other notes, in particular situations; and, at page 120, he shows also, how, when the musician, by a series of dominants, has wandered away from his principal key, may recover his lost ground, while he seems to the hearer to be persevering in the same course, by only substituting a particular note, either higher or lower, by a schisma, by a major, or by a minor comma, than the one that is written, in the ordinary notation of music, and in which enharmonic changes are all marked in his improved mode of writing music for the performer, on perfect instruments.

ENHARMONIC Degree of Aristoxenus, or Diesis quadrattrinalis, is an interval, equal \(\frac{3}{4}\)th of a major tone, or \(\frac{1}{4}\)\( T \):=25.9271353\( \Sigma +f+2m\), or 262 +\( \frac{[f+2]}{2} \)m. Some authors have called this the quarter tone major, and Mr. Boyle denominates it the enharmonical diesis.

ENHARMONIC Degree of Euclid, is an interval three-thirtieths of the minor fourth, or \(\frac{3}{30} \times 4\)th, =25.38274 \( \Sigma +f+2m\), and its common log. is =.9875601,2634.

ENHARMONIC Diesis, (greater \(\varepsilon\), or diesis greater of the mean-tone system, (see Vol. VII. p. 789,) is an interval whose ratio is \(\frac{13}{12}\), or \(\frac{51}{49}\), =21 \( \Sigma +2m \) in Farey's notation, =.9897000,4336 in common logs. =.0102999,5664 in inrecip. logs. =.0342123 in Euler's logs., =.19991591 in major comma logs., =21.0157248 in schisma logs.

In tunable intervals it is VIII—3 III., =2 VIII—3-6ths, \(\varepsilon\) 4-th =2 III +3, by either of which methods of ascending and descending, or vice versa, in the tuning process, on an enharmonical organ of Liston's, this interval may be tuned above or below any given note; already it will be found tuned thereon, above \(\%D\), \(\%E\), \(\%G\), and \(\%B\), respectively.

In the symbols explained in Plate XXX. Vol. II., the following equations will be found to express the exact relation of this interval to all the other intervals therein, viz.

\[\varepsilon = c + \Sigma \]
\[\varepsilon = 2c + 2\mu \]
\[\varepsilon = R + \pi + \theta \]
\[\varepsilon = R + \pi + \theta + \mu + 2m \]
\[\varepsilon = S - \phi + \pi \]
\[\varepsilon = S - \phi + \pi + \mu + 2m \]
\[\varepsilon = T + \pi + 2m \]
\[\varepsilon = f + \phi - \Sigma \]

In that almost endless diversity of nomenclature, in which theoretical writers on music have indulged, this interval, besides the above, has received the denomination of apotome by some writers; apotome major by Salomon, Boethius, &c.; baechius by Rameau; comma by Chladni; (see Comma, Vol. VII. p. 19,) comma greater by some writers; diesis by Euler, Liston, &c.; diesis minor by Holder; diesis major by Rameau; diminished second by Liston; harmonia by Hanfli; quarter note by Boyce, Holder, &c.; quarter tone by several; fierce wolf by Earl Stanhope, &c. It is the error \(\varepsilon\) of the trumpet, and French horn minor sixth.

ENHARMONIC Diesis of Aristoxenus, is one quarter of the major tone, \(\varepsilon T\), or his ENHARMONIC Degree, which see.

ENHARMONIC Diesis of Euclid, one-tenth of the minor fourth, or \(\frac{1}{40} \times 4\)th, or his ENHARMONIC Degree, which see.

ENHARMONIC Ditone of Aristoxenus is an interval less than a minor fourth by half a major tone, \(\frac{3}{4}\)th =4th—4\( T\) =202 \( \Sigma +f+2m\), =202.0039312 \(\Sigma +f+2m\); its common log. =.9906375.2462.

ENHARMONIC Ditone of Euclid, is an interval 24-30ths of the minor fourth, or \(\frac{3}{40} \times 4\)th, =203.20471 \(\Sigma +f+2m\), whose common logarithm is =.990690,1071.

ENHARMONIC Genus of the Greek music. See Genera.

ENHARMONIC Interval of Good and Gregory, is the Major Comma \(\frac{1}{12}\), which see.

ENHARMONIC quarter of a Tone of Rameau, is the ENHARMONIC Diesis \(\frac{1}{12}\), which see. (\(\varepsilon\)
ENTOMOLOGY.

Entomology, from ἐντόμος, an insect, and λέγειν, a discourse; the science which treats of insects, a class of animals, which were formerly arranged, along with Crustacea and Arachnides, under the general denomination of insects (Insecta), which, as we have already shown under this article Crustacology, are now universally allowed to be distinct. The word ἐντόμος is derived from ἐν, into, and τόμος, to cut; and insectum has a similar root, from in, into, and secare, to cut, because insects are divided into numerous segments, or from their being generally almost divided into two parts, which are merely attached to each other by a slender thread. The former term was made use of by Aristotle, who lived about 500 years before the Christian era, and seems to have been known much earlier than his time. It is defined by him to signify an animal which, by incisions, is severed into two or more parts. The latter word, insectum, is adopted by Pliny, and was in use among the Latins long before his time, and we find it applied in the same sense as the ἐντόμος of Aristotle.

As the animals of this class constitute the most considerable portion of animated beings, it becomes one of the most interesting and important sciences which can engage the mind of the philosopher. The extreme difficulty of discriminating the characters and particular affinities of these beings, arising from their number and variety of form, in addition to their minuteness, more strongly claims his consideration. He who neglects the study of insects, or thinks it beneath his notice, cannot deserve our respect, as a general observer of nature, nor be considered a scientific naturalist. The views of such a man will be partial, and his inquiries circumscribed; he regards only an inconsiderable portion of animated nature; and he confines his remarks to such as, from their size and distinctness of character, present the least obstacle to investigation. In the study of entomology, the man of science will find abundant scope for the exercise of his zeal. The amazing number of species; their curious forms, so infinitely varied, and yet so nearly and gradually approximating through an endless series of transitions from one species to another; the diversity of structure observable in those parts which afford generic characters, added to the wonderful changes in form which they undergo, with their surprising economy, are circumstances which contribute to render them objects of most curious speculation to the philosopher. And although the study of every class of animals is most indisputably attended with peculiar advantages, yet we shall venture to affirm, that it is from a knowledge of the characters, metamorphoses, and various modes of life, these little animals are destined to pursue, that he will obtain a more intimate acquaintance with the great laws of nature, and veneration for the Great Creator of all, than can be derived from the contemplation of any other class in nature. Many other attractions accompany the study of this department of science. The beauty of insects in general, renders them engaging to many who have neither time nor inclination for studying their more complicated structure; and the gaiety of their colours, often combined with the most graceful forms, displays a beauty, splendour, and vivacity, greater than that bestowed by the hand of Nature on any of her other works. One defect in appearance must indeed be conceded; and this may be regarded, in point of beauty, a material defect; they are not always so considerable in magnitude as to become, even with these embellishments, so strikingly attractive. Were they equal in size to the smallest birds, their elegance would render them more inviting in the eyes of mankind in general; but, even amongst the minor species, when examined with a microscope, we find their beauty and elegance far superior to that of any other class in nature. "After a minute and attentive examination," says Swammerdam, "of the nature and structure of the smaller as well as the larger animals, I cannot but allow an equal, if not superior, degree of dignity to the former. If, whilst we dissect with care the larger animals, we are filled with wonder at the elegant disposition of parts, to what a height is our astonishment raised, when we discover these parts arranged in the least in the same regular manner!"

Insects may be divided into two kinds; those which are immediately or remotely beneficial or injurious to mankind. Many insects certainly seem not to affect us in any manner; others, and by far the greater number, most assuredly fall under one or the other denomination, and surely on this account demand our most serious attention; but, lest our allusion to the utility of some insects should seem hypothetical to the superficial observer, whilst the noxious effects of others are too obvious to admit of doubt, we shall be more explicit in this observation. The depredations of insects upon vegetable bodies, are often detrimental; but it must be remembered, that in these ravages they often repay the injury they commit. The locust, the most destructive of all insects, whose numbers spread desolation through the vegetable world, are not (except on some occasions when their multiplication exceeds all bounds) unproductive of advantage. Although they deprive mankind of a certain portion of their vegetable food, yet, in return, their bodies afford nutriment of a wholesome and palatable kind, and in much greater abundance. The various species of locusts are the common food on which the inhabitants of many parts of the world subsist at particular seasons. The honey of bees, in many warm climates, constitutes another primary article of food. The caterpillars of several moths furnish materials for the silken raiment so universally worn by all ranks in the eastern parts of the world; and hence, in these countries, the silky produce of these industrious little animals is of so much use as the fleecy coat of the sheep is to us. As an object of traffic, silk is one of the utmost importance in China and Tartary; and, in those parts, paper is manufactured from the refuse of the same material. The extensive use of wax in all ages, is well known; but it is less generally understood that all wax is not produced by the bee alone; the wax-insect of China is a very distinct animal: (See Cicada, Index; and Donovan's Insects of China). Some insects are used with success in medicine; and many others (the cochineal, for instance) are rendered useful in the arts: and greater numbers might perhaps also be employed for the same purposes. These few, out of a vast many more instances, are sufficient to prove the absurdity of an opinion very prevalent, "that insects are too insignificant to deserve the attention of
the philosopher." But allowing these benefits to be unknown, and that the study of entomology is not productive of any substantial advantages, how absurd would it still be to treat with an extensive portion of the creature with neglect! The objection, that they are in no wise conducive to our interests (even if founded in truth), would be no evidence of the frivolity of the science, unless we are to conclude, that the only inquiries which merit our rational attention are those which tend to the gratification of selfishness. If this be admitted as an objection, how many objects of philosophical investigation must be rejected as frivolous! From the earliest period in which the light of natural knowledge dawned, this class of animals has obtained considerable attention; and although the study has not at all times been cultivated with equal ardour, yet we shall hereafter be enabled to prove that it has not been utterly neglected, but has engaged the study of men endowed with talents as splendid, and judgment as refined, as the most exalted of those who affect to treat it with contempt.

HISTORY.

From the earliest period of which any authentic records remain, this science has obtained a very considerable portion of attention; but the total destruction of the great public libraries, has deprived us of the means of ascertaining to what state this branch of science had attained, till within about 2000 years of the present time. We shall now endeavour to lay before the reader an account of these works; and, as we deem the subject of importance, shall, as far as our limits will allow, mention every work, however slight, which has been productive of any material information; at the same time, we wish it to be understood, that we do not consider it necessary, or within our province, to enter at large upon a critical analysis of the multitude of writings before us, but only such as we have had an opportunity of consulting with attention, describing the leading intention of their authors respectively, which we shall enumerate as nearly as possible in chronological order.

Some books appear to have been written prior to the date of those which have descended to us, as we infer from various hints recorded in the earliest of those works now extant.

The oldest records on this subject are to be found in the sacred writings, where mention is made of locusts, flies, and caterpillars; and it is probable Moses had acquired a slight knowledge of this science from the Egyptian sages, as his works abound with passages relating to insects; and amongst the obsolete works of Solomon, he is said to have treated of "creeping things."

Hippocrates, who lived about 500 years before Christ (as we are told by Pliny), wrote on insects. The writings of the earlier Greek and Latin philosophers, quoted by Pliny, afford extracts of his labours.

Aristotle flourished in the succeeding age. He wrote, amongst many other works, a History of Animals, an elementary book, giving a general and comprehensive view of the animal creation; but he rarely descends to the description of species. It is a work of the greatest merit, which no one can impartially peruse without confessing the intimate knowledge its writer must have possessed of nature. The insect class is treated of in several parts of his work. In the seventh chapter of his first book, we find the term insecta is that of a family, which constitutes one of his four orders of animals with colourless blood. The animals he terms exsanguinosi; and, in his definitions, he points out, with great accuracy, in what they differ from the divisions of this class, viz. Mollusca, Crustacea, and Testacea. In the first chapter of the fourth book, we find the essential characters more clearly given, namely, the incisions on the back or belly, or both, by which their bodies appear to be divided into two or more parts. In another part of his book, more particularly devoted to insects, he describes them as having three parts, the head, trunk, and abdomen: the second part is denominated an intermediate portion, corresponding with the back and breast of other animals. He also adds, they have feet. In subsequent passages, he describes insects which fly, and those that walk. Amongst the former, he notices those with naked wings, and those covered with a sheath; and he observes, that some of these have the sheaths divided, and others immovably connected. The naked winged insects are of two kinds, some with four, and others with two wings. Some of those with four naked wings are furnished with stings at the extremities of their bodies, whilst those with two are destitute of this apparatus. He describes, with attention, the horns (antennae) of the butterflies and locusts. When noticing the legs, he remarks the leaping feet of the locusts, which he compares to those of springing animals. The accuracy with which this learned philosopher has described the various parts of these animals, cannot but astonish the learned entomologist; he will be surprised at their consistence. Their accordance with the entomological definitions of the modern systematists, will excite further comparison; and the natural result will be, that, with the acquired knowledge of 2000 years, so far as he does proceed, we, until lately, have been unable to amend his observations. A cursory perusal of the whole work will show, that whatever might be the merits of this great man, his writings evince too much acquaintance with the science of nature to be the produce of any individual genius, shining with unborrowed light; for, when we reflect on the slow manner in which all human knowledge is developed, we are readily convinced that the science of nature must have made some considerable advancements before his time; and that he has derived considerable assistance from the works of more ancient naturalists.

Elian, in his work on animals, Dei Cons, appropriates several chapters to insects, without entering into the system at large, confining himself to particular kinds; and those noticed are described with attention, as crickets, the generation of wasps, of cantharides, &c.

Amongst the Greek writers who immediately, or within a few centuries, followed Aristotle, were Democritus, Neopolemus, Philigius, Nicander, Herodius, with many others of less note. These writers were probably concomitants with Pliny; and, during the same period, several Latin writers seem to have been induced to pursue this science, through the influence of the Greeks, who were insensibly led to it from attending to the culture of bees, which at that time was attended to with the most enthusiastic ardour. Aristarchus of Soli is said to have written on the subject, from the result of fifty years experience; and Philiscus to have employed his whole life in forests and deserts attending to their history.

Pliny, in the eleventh book of his Naturalis Historia, treats of insects. His observations are chiefly copied from the work of Aristotle. In his day, the culture of silk-
worn was an object of attention. He says that garments of silk were much admired in his days by the fair sex, as it shewed their form to advantage from the delicacy of its texture.

From the time of Pliny till the overthrow of the Roman empire, the study seems not, to have been totally disregarded; but we are ignorant what steps were advanced during that period. Amongst the writers were Titus, Aesopus, Alexander, Orisbiuss, Trajan and Ptolemy Augusta, who lived between the fourth and seventh century. Between the ninth and twelfth century, some of the Arabian botanists distinguished themselves as entomologists. The principal were Rhazes, Avicenna, Avenzoar, and Avemroes. From this period till the fifteenth century, a few obscure writers, scarcely worthy of notice, appeared, viz. Myrcus, Platerus, &c.

Albertus Magnus. Albertus Magnus wrote a geological work, entitled, De Animalibus, part of which treats of insects. He died 1280, but his work did not appear until the year 1519, being printed at Venice.

Agricola. In 1540, Agricola published his work, De Animalibus Subterraneis, which contains a systematic arrangement of insects. He reduces all insects to three principal classes, viz. 1. Those that walk; 2. Those that fly; and 3. Those furnished with swimming feet; and describes a number of species.

Wotton. In 1552, Edward Wotton published a work, entitled, De Differentiis Animalium, in which he treats largely on insects. The book is in folio, and appeared three years before the author's death.

Rondeletius. In 1555, Rondeletius of Montpellier gave his valuable work, "Universa aqultilium Historia para altera," to the world, in which he treats of insects, which he accompanies with wooden cuts.

In 1599, in folio, was published at Naples, "Ferrante Imperato dell' Historia Naturale libri 28." In 1602, a very voluminous work was published, entitled, De Animalibus Insectis, by the "indefatigable compiler" Aldrovandus. Donovan is inclined to give him considerable credit. He has certainly acquitted himself in collecting together the undigested observations of the ancients; but from his entire ignorance of the subject, he has necessarily fallen into all the errors of his predecessors: we must, however, allow, that he has acted with candour, having rarely omitted to mention his authorities. He was professor of medicine at Bologna, and employed much of his time in the study of insects, and expended large sums of money in acquiring specimens, and employing artists to figure them. He is stated to have paid two hundred florins annually to an artist, who was occupied solely in the delineation of insects. He divides insects into two great orders, 1. Terrestrial; 2. Aquatic; which he terms Insecta forica, and Non forica: these he divides into sub-orders, from the number and situation of their wings and feet. His figures are but rudely expressed, which is excusable. At this time a taste for more expensive embellishments began to prevail, but as the art of engraving on copper had scarcely emerged from its infancy, these works were exclusively produced by artists themselves.

In 1612, the Historia Animalium Sacra, by Wolfgang Frenzini, dividing insects into three classes, 1. Aerina, 2. Aquatica, 3. Terrena, and containing several new observations, appeared: and three years afterwards, in the year 1616, at Rome, a pamphlet of about one hundred pages, in Latin, entitled, De Formis, by Jeremiah Wilde.

In 1622, a work but remotely relating to insects, in 4to, appeared in Edinburgh; bearing the following title, "Hieroglyphica Animalium Terrestrium, &c. quae in Scripturis Sacris inventur et plurium aliorum, cum corum interpretationibus;" which, being the first work relating to insects published in Britain, is not unworthy of notice as a curiosity.

In 1630, a thin quarto, by Hoefnagle, was published under the title of Diversa Insectorum volatilium Icones ad viuem depictae, per D. J. Hoefnagle, typique vandale a Nicolao Johanni Vischer, containing 326 figures, some of which are very indifferent. He has not adopted any particular mode of arrangement, but contented himself with delineating them in the states presented by chance, not always following them throughout their progressive changes.

In 1634, Thomas Moult published his Insectorum sive miniorum Animalium Theatrum, which appears to be the second work on entomology published in our country. This work, as its title indicates, is written in the Latin language; it appeared in London in one volume folio, and contains numerous wooden cuts, rudely executed, accompanied by long, tedious, and often ridiculous and fanciful descriptions of the species. The first seven chapters (capitula) are occupied with heavy details concerning the common hive bee (Apis Mellifera). The eighth is entitled, De Vespis. The ninth, De Crebrone et Tenredine, which includes the humble bee (Bombus). The tenth, eleventh, and twelfth, De Muscae, which includes, with several diptera (two-winged insects) many hymenoptera, as well as neuroptera insects. The thirteenth, De Culicibus. The fourteenth, De Papilionibus, which occupies two hundred pages, the margins being embellished with 112 wooden figures, executed in the rudest style, yet in most instances tolerably intelligible to the skilful entomologist. The fifteenth De Cicindela, including the glow-worm (Lampyas) and several others. The sixteenth, De Locustis. The seventeenth, De Cicindis et Gryllis. The eighteenth, De Blattis. The nineteenth, De Buprestis et Cerambe. The twentieth, De Cantharide. The twenty-first, De Scarabaeis, which includes many of the larger beetles, (Coleoptera). The twenty-second, De Scarabaei Minora. The twenty-third, De Proscarabaeo et Scarabaeo Aquatico. The twenty-fourth, De Gryllotalpa. The twenty-fifth, De Phylargyra. The twenty-sixth, De Tipula. The twenty-seventh, De Forficula stellitica auricularia. The twenty-eighth, De Scorpionis, Forica, et Pediculcs alatis. And, lastly, the twenty-ninth, De Cicimae Sylvestri. After these, we arrive at the second book, which treats of apterous insects, (those wanting wings), amongst which he places all sorts of Larvae (or caterpillars) of other species belonging to winged insects, and likewise many of the mites, &c. We must apologise to the reader for taking up so much of his time with dry statements of the heads of this work; but as it was one of the first produced in this country, we trust he will not consider it as entirely uninteresting; and as a specimen of his style and notions relative to insects, we may quote the following, which speaks of a species of Mantis, (probably M. religiosa or Oratoria): "Pectus habet longum, tenue, cuculo tecum, caput simplex; oculos sanguineos, satiis magnos, ar-
EN TOMOLOGY.

History.

tenias breves, pedes sex locutariam more, sex atteriores
multo crassiores longioresque cuteris, quos quin junctos
plerumque elevat (precantium ritu) a nostratibus
presque Diei dici solebat: totus corpus maculamentum est.
Tam divina censitur bestiata, ut puero interroganti de via,
dalere pede extenso rectam montalae, atque raro vel
munqnum fallat. Cauda illi bifurca, setae subdus acutae
pradita: atque ut numan elevationes vates referit, ita
etiam et mutus similitudine; neque enim ludit ut alii,
quae salta, quae gestit: sed lente obtubans mod-system
destinat retinet et maturum quamost ostendit gravita-
tem." The work is professedly an improvement on that of
Dr Wotton, begun in 1550, continued by Conrad Ges-
ner; and was afterwards enriched and published in its
present form by Moufet.

In 1646, Hollar gained considerable reputation by his
work, Musearum, Scarabeorum, Vermumque variam
figure et forme, omnes ad vitam coloribus depictae et ex
collectione armiliana, &c. which was published at Ant-
werp.

Johnston.

In 1657, the Historia Naturalis of Johnson, in folio,
was published; but as this work is a mere compilation,
it is unworthy of further notice; for "he has not added a
single remark to what was before known."

Topsal.

In 1658, an English translation of Moufet's work
was published in London by Topsal, chaplain of St Bo-
tolph.

Goedart.

Goedart, about this time, published a work in the
Dutch language, with plates. This work, considering
the time of its appearance, must be considered of con-
siderable merit. It has been translated into Latin,
French, German, and English, with copies of the plates.
"For the space of twenty years," we are told, "Goe-
dart devoted himself to the study of insects." He
followed them through their progressive changes with
great precision: this renders his book more extensively
acceptable; and his figures, which were never surpassed
by his predecessors, are sufficiently correct to be under-
stood. The first edition of this work being sold off, the
first volume of a Latin translation, by Dr Mey, min-
ister of Middleburg, was produced, under the title of
Metamorphoses et Historia Naturalis Insectorum, in 1602.
Lister allows but little credit to the translators of his
works; "Goedart," he observes, "left his writings in
Dutch; his translators were men wholly ignorant of
natural history, and their comments are mere rhapsodies
altogether."

Power.

In 1664, a quarto relating to insects as objects of mi-
icroscopical investigation, by Power, was published.

Hook.

In 1665, Hook's Micrographia appeared; and, like
the former work of Power, treats of minute insects.

In 1666, was published in quarto, Adamo Olearii Got-
torffische kunst-kamer Slensig.

Merret.

In 1667, Pinax rerum naturalium Britannicarum, con-
tinens Vegetabilia, Animalia et Fossilia, in hac insula re-
porta inchoatos, by Christopher Merrett, M.D. was pub-
lished in London. This is the first work treating exclu-
sively of the insects of Britain: it contains a brief ca-
tabogue of such as were known to Dr Merrett, each being
accompanied by a concise descriptive sentence by way of
name. In the first volume of the Transactions of the
Entomological Society of London, an account of the in-
sects given by this author, with their systematic names,
is given by A. H. Handorth, Esq.

Charleston.

In 1668, Charlton published a work in London, with
a systematic arrangement of insects, after the manner of
Aldrovandus, entitled, Onomasticon Zoicum, &c. 4to.

In 1669, was printed in Dutch, with a Latin title, Swammer-
dam's Historia Insectorum Generalis, &c. by the
illustrious Swammerdam. This work was printed in 4to.
(and has since undergone several editions, which we shall
mention in their proper order), illustrated with thirteen
copper-plates. Many years elapsed before the excellence
of this work, the admiration of later times, was in any
manner acknowledged. It was condemned as inaccurate
until the death of its learned and generous author, ac-
knowledging one of the many examples of that culpable spi-
rit which living merit so rarely fails to experience, for
labours bestowed for the benefit of an ungrateful
world. No sooner was his death announced, than his
merits were discovered, and his work was rendered
into French by an anonymous translator: this and
many other editions soon after followed. The sys-
tem of this author is interesting; we shall therefore give
a short sketch to our readers. He divides insects into
four classes, the characters being taken from their meta-
morphoses and economy. The first undergo no change,
and includes spiders, onicei, &c. (which are noticed un-
der our article Crustaceology). The second class in-
cludes those which, after leaving the egg, appear under
the form of the perfect insect, but have no wings; in
which state it eats and grows, till, having passed the chry-
salis state, it issues thence with wings, and is in a condi-
tion capable of propagating its kind. This class com-
prehends the orders of insects Orthopera, Dermopera,
Dictopera, Hemipera, and Neuropera, of this work.
In the third class, we find those insects which appear
when hatched from the egg, under the form of a cater-
pillar (Larva,) which when full grown, changes into a
chrysalis, where it remains until the parts are fit to be
developed. The insects included in this class are the
orders, 1. Coleopera, and 2. Apera, (Lamark); Sucto-
rina, (Latreille); whose larvae divest themselves of their
skin before transformation. The fourth class com-
prehends those who having attained the pupa (or chrysalis)
state, do not divest themselves of their skin. The in-
sects alluded to are the orders Diptera and Hymenoptera
of modern entomologists.

In the same year Wolf's Dissertatio de Insectis, &c. was
published at Leipsic. The author was professor of me-
dicine at Jen.

In 1671, Redi published his Experimenta circa gene- Redi,
rationem Insectorum, in which he combats the long-maintained
docrine of equivocal generation with success;
proving by experiments and close reasoning, the fallacy
of such opinions. At the end of this book he has given
figures of the lice of birds.

In 1671, Claude Perrault, one of the most learned Per-
ault, exotic entomologists of his age, author of several
ingenious papers in the Memoirs of the French Academy,
published a folio work at Paris, entitled, Memoires pour
servir à l'Histoire naturelle des Animaux.

In 1672, Ferrard published a work at Naples, of Ferrard.
which we have no account, nor have we met with it.

In 1673, Franzelio submitted his Insecta Nisivollis Franzelio.
cum nive delapsa to the world.

In the same year, at Frankfort, was published by
Mollerus, Medicina Insectis quibusdam Hungaricae Molle-
rum, prodigiosis anno proxime praterito, ex aere una cum nive
in agros delapsa, ornamented with wooden cuts.
In 1675, a tract on the natural history of the Ephemeræ horaria, by Swammerdam, appeared, entitled, Ephemeræ Fita of afbeeldingh van 's-menschhen leven, vertoont in de Historia von het uiligt ende een-daghelevent Hofst. of Oever-ans.

And in the same year, an elementary tract by George Belcher, printed at Upsal, priete verenij.

About the same time, also, by Samuel Bochart, a work entitled, Historia animalis Sanctae Scripturae.

In 1676, some additions to Claude Perrault's work were published.

In 1679, Madame Maria Sybilla Merian, vel Graffin, produced the first part of her work, "der Raupen wunderbarer verwandelung und sonderbar blumen-nahung," which relates principally to European lepidopterous insects. The author's was a native of Frankfort on the Maine, wife of John Andrew Graffin. In early life, she imbued a taste for the study of insects, from being occupied at times in painting these objects as ornaments to her flower-pieces. The task of painting insects she performed with tolerable accuracy; yet there is "a peculiar exuberance of style incompatible with any faithful resemblance of nature." Many of her original drawings are preserved in the British Museum as specimens of her style.

In 1680 was published, Johannis Jacobi Wagneri, Historia Naturalis Helvetiae curiosa. Figure.

In 1681, Grew published his Museum Regalis Societatis; being a catalogue and description of the natural and artificial rarities belonging to the Royal Society of London, preserved in Gresham college. London. Folia.

In the same year, an English translation of Swammerdam's Ephemeræ Vita was produced in London, and a French translation in Paris.

In 1682, a book entitled Johannes Godartiis of Insects, done into English, and methodised, with the addition of notes; the figures etched in copper by Mr P. Fbl, was published at York. It is supposed to have been translated by Lister; the initials M. L. are at the close of the address "to the reader." The impression, as we learn from the preface, consisted of one hundred and fifty copies, which were intended merely for the curious; and the notes are copious.

In 1682, Hoppius published a dissertation on the Gryllus migratorius.

In 1683, the second part of Merian's Der Raupen, &c. appeared.

In 1685, the first Latin edition of Swammerdam's work was printed in Lyons, under the title, Historia Generalis Insectorum, Latinam fecit H. C. Hennius.

In this year also, Lister's Latin edition of Godart, entitled, J. Godartii de Insectis in methodum redactus, cum notularum additione, opere, M. Lister, in octavo, appeared in the Latin language. The author distributes the materials into a new form of arrangement, the merits of which are too obvious not to be considered as an improvement on the original production. He divides them into ten sections, as follow.

2. Those with their wings placed horizontally, and which proceed from caterpillars, called geometra by Godart, from their gait. Moths.
3. Those with deflexed wings. Moths.
4. Libellule, or dragon flies.
5. Bees.
7. Grasshoppers.
8. Diptereus, or two-winged flies.
9. Millepedes. (Now Crustacea.)
10. Spiders. (Now Arachnid.) See the article Crustacologia.

Although we readily allow Lister the credit due for this arrangement, yet we cannot avoid expressing our regret for his remarks on the original author, to whom he allows neither credit as a naturalist nor as a writer. He highly praises his skill as a painter; but says, "Goedart, after forty years attention, seems to have made but little advancement in his skill in the nature of insects; he rather seems to have diverted himself, than to have given himself any trouble to understand them; and yet after all, you will find him everywhere just and correct, but in many places short and hardly intelligible." These opinions are delivered in a style of affected superiority over his author, highly unbecoming and not strictly true; and he gained no reputation on the continent for these illiberal remarks, which were much condemned.

Also, by the same author, Appendix ad histriam animalium Anglica. London. Octavo.

In 1687, Leeuwenhoek published his Anatomia seu in- Leeuwen-teriora rerum, cum animataram tum inanimataram, ope et beneficio exquisitissimorum microscoporum detecta.

In the same year, Geyereus wrote a treatise on the medicinal properties of Spanish flies, (cantharides,) under the title, Tractus physico-medicus de cantharidibus.

Also by J. F. Griendel, at Neuremberg, in quarto, Griendel, Micrographia Nova, in which some notice is taken of insects.

In 1688 was published an Italian edition of Redi's Experimentera circa Generationem Insectorum, entitled, Esperienze intorno alla Generazione degli Insetti.

In this year also, Stephen Blankart, of Amsterdam, published a work, Schon Berg der Raupen, Worner, Muden en vliegende Dieckens naar uit voort-komende. The author was a physician, who devoted much time to collecting insects. The plates are admirably executed; but the work in other respects bears an indifferent character. Frisch and Lyonet consider it but a superficial production. It treats of the larvae of various insects, and a few perfect insects are also noticed. Another edition was published at Leipsie in 1690.

John Cyprien also published at Frankfort, Historia Cypri-Animalium, in the same year, in which insects are noticed.

About this period, two papers on insects appeared, one by John de Muralto, the other by C. Montezuliuus.

In 1690, Bilberg published at Upsal a dissertation entitled, Locuste.

And in the same year, König's Regnum Animal. In this year also, Stephanus Blankard published in octavo, at Leipsie, Schön-burg der Raupen, Worner, Muden. In 1691, Historia Vernium, by Jungius, was printed Jungius at Hamburgh.

In 1692, in the Memoirs of the French Academy, we Sedileau, entitled, Observations.
In 1693, an augmented edition of Swammerdam's *Historia Generalis Insectorum Latinam seu H. C. Hen- nius,* was printed at Utrecht.

In this year, the prodigious ravages occasioned by immense swarms of locusts, which, in the month of August, over-run Germany, and extended partially through the rest of Europe, even to the northern borders, could not fail to engage the observations of many writers, among whom we find the following naturalists, *De Locustis immenso agmine aëreum nostrum impludentibus, et quid porten- dere putentur,* by Hcnestrecht; also *Disertatio de Locustis,* anno præterito immensa copia in Germania visis, cum diatriba, qua sententia autors de *Hyli defenditur,* by Ludolphus. The former of these works is printed in sixty-five pages, with one plate, from which we learn the species treated of to be *Grillius migratorius.* The work of Ludolphus is in folio, and consists of eighty-eight pages, embellished with figures. The following authors also published tracts on this subject, namely Cretillus, Kirkmajor, Woellenhaupt, and Treunera, but we are ignorant of the titles of these little dissertations.

In 1694, Albino published a small tract on the Spanish flies, *Cantharides.*

In 1695, the *Arcana Naturae Detecta* by Leeuwen- hoek, appeared.

And in the same year, a small octavo, Jacob Petiver

*Museum.*

In 1699, Hombergh published a paper in the Memoirs of the French Academy, on *Agrion virgo.*

In 1700, was published, in three volumes duodecimo, *Histoire Naturelle des Insectes selon leurs différentes metamorphoses, observées par Jean Godart.* Amsterdam.

Petiver. In 1702, James Petiver produced the first decade of his *Gazophylacium natura et artis,* which was carried on progressively till about ten years afterwards. It consists of ten decades, which treat of insects, as well as larger animals, fossils, and plants.

Rumphius. In this year also, the entomological part of the work of Rumphius appeared.

In 1707, appeared in London, *A Voyage to the Islands of Madeira, Barbadoes, Jamaica, with the Natural His- tory,* &c. by Hans Sloane. Folio.

In 1710, Russell published his *Theatrum universale omnium animalium,* which treats of insects.

And the illustrous Ray's *Historia Insectorum,* under the care of Dr Derham, after the author's death, appeared. In this work, he divides insects into two principal classes, such as undergo transformation, and those that do not; and these he subdivides into several orders. He includes amongst these some vermes, which have again been removed by Linnaeus, as we shall have occasion to mention hereafter.

In 1717, Wedelio published a tract on the utility of *Cantharides* in the materia medica, in Jena.

And in the same year, J. Petiver, an entomological writer, published a work, *Papilionum Britannicorum Icones, &c.* in folio, London, which in its time was certainly a valuable publication to the student of entomology, and even now, as a work of reference, is in high repute.

In 1720, Fabric published his *Beschreibung von Insecten in Deutschland:* the whole work consists of thirteen parts, each being illustrated by three plates.

In this year, Eleazar Albin published in London, *A Natural History of English Insects,* with one hundred copperplates, in one volume quarto.

In 1722, *Opera Omnia,* containing all the works of Leeuwenhoek.

In 1725, Sir Hans Sloane published in London, the Sloane second volume of his *Natural History of Jamaica,* the second book of which treats of the insects of that island, accompanied by several uncoloured plates.

In 1726, Merian published at the Hague, in large folio, *Merian's De generatione et Metamorphosis Insectorum Surinam- ensium,* the materials of which were collected by himself, or under his directions, in Surinam, where he spent two years, for the sole purpose of forming a collection, and in taking drawings for this work; which is not, however, entirely devoted to entomology, for besides insects, we find depicted plants, and various reptiles, as toads, lizards, serpents, &c.

In 1730, Valisnieri, in *Esperienze et Observationi Valisniere intorno agli insetti,* distributes all insects into four classes, from their habitats. The first comprehends those which live on plants; the second, such as live in water; the third, those that live on earth, or amongst stones; and the fourth, those which subsist on other animals.

In 1731, was published in one volume quarto in Lon- don, *Insectorum Anglicarum Historia illustrata Leoni- nus in centum tabulis aversa eleganter ad vivum expressis,* &c. by Eleazar Albin, and was esteemed an elegant work; but, we must confess, it is more remarkable for gaudiness than fidelity.

In 1734, the first volume of Reaumur's *Memoires pour servir à l'Histoire des Insectes,* was published in Paris. The five succeeding volumes appeared between that time and 1742.

In 1734, Alberti Sebba, *Lecupin轰炸 rum natura- lium Thesauri accurata descripitione, et iconibus artificiali- simis expressio Latinâ et Gallice,* tom. iv. folio. The first volume appeared in the above year, the other three before 1675.

In 1735, the illustrious Swedish naturalist Linnaeus published the first edition of *Hs Systema Nature,* sive *Regna tria Natura Systematicâ disposita per classes, or- dines, genera et species,* in which he distributes insects into four orders, according to the number and form of their wings, under the names, 1. Coleoptera; 2. Anthophota; 3. Hemiptera; 4. Aptera. In the first, are contained those whose wings are covered; the second, those with naked or uncovered wings, as butterflies, dragon flies, ephemera; &c.; the third, locusts, bugs, &c.; the fourth, those without wings, as lobsters, spiders, lice, &c. Besides these, several animals, which, in later editions of the work, Linnaeus considered as vermes, were included. These were the earth-worm (*Lumbricidae*) the leech (*Hirudo*), all land and sea shells, and staf- fish (*Asterias*) sea-egg (*Echinus,* &c.); and in this arrangement, lie hy no means derived from the received opinions of his time. In the subsequent editions of his.
In 1736, all the works of Swammerdam were put to press, entitled *Biblia Natura*, sive *Histori Insectorum Belgicarum, cum versione Latina*, H. D. Gauth. et vita autelis, per H. Boerhaave. The first volume appeared in 1737, and the second in the year following.

In 1738, *Lapland*; *octavo*, is it? It is a work by H. Boerhaave.

In 1739, Linnaeus published a work, entitled, *F. C. Lessner Insecto-Theologia, oder Vernunft-und Scheffsumziger Versuch, wie ein mensch durch unfererwisse Betrachtung der sonst wenig beachteten Insecten, &c. Frankfort and Leipzig, in octavo. This work has never come under our inspection. We have, however, noticed a French translation, which appeared in 1742, at some length.

In 1740, the folio work of *L'Admiral*, entitled, *Naarmeeuwer Waarnemingen van Gestaltverwisselende gekeerwene Dierfjes*, was published at Amsterdam. It contains a series of highly finished etchings, which are distinctly copied by Harris in his *Aurelian*. This work is confined to the insects of Europe, and contains figures of about fifty of the larger species, principally of lepidoptera, which are represented in various attitudes, with large branches of the plants on which they feed, generally accompanied with their larva and pupa. It began in numbers, and was intended to contain one hundred plates, and four hundred pages of letter-press, but the work was discontinued. Most copies of the work contain twenty-five plates, and five pages of print; but Mr Donovan's copy, which is the most complete that we have seen, contains thirty-two plates, and twenty pages.

In 1741, *Naarmeeuwer Waarnemingen van Gestaltverwisselende gekeerwene Dierfjes* was published at Amsterdam. It contains a series of highly finished etchings, which are distinctly copied by Harris in his *Aurelian*. This work is confined to the insects of Europe, and contains figures of about fifty of the larger species, principally of lepidoptera, which are represented in various attitudes, with large branches of the plants on which they feed, generally accompanied with their larva and pupa. It began in numbers, and was intended to contain one hundred plates, and four hundred pages of letter-press, but the work was discontinued. Most copies of the work contain twenty-five plates, and five pages of print; but Mr Donovan's copy, which is the most complete that we have seen, contains thirty-two plates, and twenty pages.

In 1742, a French work, being a translation of *Lesser's Insecto-Theologia*, with remarks by Lyonnaix, entitled, *Theologie des Insectes, ou Demonstration des Perfeotions de Dieu dans tout ce qui concerne les Insectes. Traduit de L'Allemand de Mr Lesser, avec des remarques de Mr Lyonnaix a la Haye, octavo*, appeared. The original work we have never seen; it appeared in 1738. The views of the author are to promote the glory of God; nor did he in any degree attempt to establish any new facts relative to entomology, but directed his attention to the collection of such anecdotes relative to the natural history of insects, as could be rendered a convenient medium for the theological remarks with which his pages abound. To the entomologist, the work is of no use; for his knowledge was but limited, and his remarks often erroneous. As a theological production, however, it may have an useful tendency, as it is calculated to expose the glaring errors of others, who, with a fanatical spirit, had entered on the same subject. One of the best chapters relates to the abuse of insects in theology. He says, the Jews are accused of stating many wonderful things relative to insects, which can only be considered as fables. Amongst many instances, after repeating the text, Kings i. 6, 7, concerning the erection of the temple, "And the house, when it was in building, was built of stone, made ready before it was brought thither: so that there was neither hammer nor ax, nor any tool of iron heard in the house, whilst it was building," he states, that the Jews explain this passage in the following manner: The workmen (they say) employed a worm to shape the stones; which insect, named *Schamir*, cut and broke them to pieces in places where applied. They add, that it was "figured like unto a grain of barley," and was kept in a leaden box, "because it had reached rocks, it would have left them, so as to unfit them for use." This fable, with many others equally absurd, invented by the rabbis, is particularly mentioned. Amongst the legends of Catholic superstition, too, he selects several anecdotes equally fraught with folly, which, if really believed in the time of Lesser, will excite him (he being a divine) for applying his time to the exposure of such gross absurdities. Two of these anecdotes we shall take the liberty of inserting. Balduin relates, that a number of bees accidentally passing over holy ground, paid it homage, and carried a portion respectfully to their hive; and it is stated that St Francis, when walking in his garden, saw a grasshopper, which immediately pitched on his hand, and, at his command, sung psalms and praises to God.

Detharding also, this year, published *A Disquisitio physica Verniun in Norvania qui neea vasi, in quarto*. It is a small treatise, relating to the larvae of *Phalana*, or mollusks.

In 1748, George Edwards published the first volume of *his Natural History of uncommon Birds*, and of some rare and undescribed animals, *London, quarto*. Three other volumes appeared before 1752, in which several insects are given.

In 1744, at Stockholm, was published by Degeer, a Deger's little work in octavo, on the utility of studying insects, entitled *Tal om nyttan, som Insecte ochdcras skapade, tillknytta oss*, pointing out the advantages of cultivating the natural history of those animals, and, as far as we know, is the oldest work on this subject.

In 1745, *Ejudden Olof och* *Gottlind's Rcsa fdr reallid 3r, 1741, Stockholm och Upsala*, 1745, one small volume octavo, by Linne.

In 1745, *Der monatlich-herausgegebenen Insecten* was published.
ENTOMOLOGY.

History.

lustyung, by Rösel of Nuremberg: a man of genius, by profession a miniature painter. The work is in quarto. Two other volumes appeared in 1749 and 1755. To these a fourth volume was added by a relation (Kleemannir) after his death in 1761; and, since that period, Kleemanirh has published three other parts.

In 1747, a tract, explaining the advantages arising from the study of insects, entitled, Disseratio de Usu Cognitions Insectorum, was published by C. F. Menander. In the same year, William Gould published in London An Account of English Ants.

In 1748, was published in London, by J. Dutfield, six numbers of a natural history of English moths and butterflies.

Also Dutfield, in this year, T. C. Hoppe published two small entomological tracts, as Antworts-Schreiben auf Herr Schreibers zweiten und Eichen-Weiden-und Dorrosen. The first at Gera; the second at Leipzic.

In the same year, or perhaps earlier, the splendid work of Benjamin Wilks, under the title of The English Moths and Butterflies, together with the Plants on which they feed, and are usually found. The plates, which appeared first, bear no date. In the third volume of Rösel's work, Insecten Bestüting, we find comments on this work, not to the credit of English entomologists in general, when the science ought, from the labours of former writers, to have stood on very high ground in this country, and the public judgment to have been so far matured as to discover impropriety. Rösel, in the plainest terms, accuses our author of piracy; and, when we reflect on the celebrity this work has heretofore enjoyed as an original production, it certainly attaches some little reproach to our naturalists, that facts, so publickly asserted on the continent, should have remained unknown to us. As the remarks are curious and interesting, we shall copy this part translated by a friend. "In the supplement, or third part of my amusements of insects, I have mentioned a certain work which Mr Wilks in London continues monthly, and promised that I should take some opportunity of giving a more circumstantial account. Since then the plates amount to ninety, all of which I have examined with great attention. They are as yet destitute of any description, which is, however, promised at some future period. In the notice to these plates, he professes to have drawn them from life; but, by those acquainted with other works, it will readily be discovered that several are taken from Albin's work, from Mcrian's book, and many from my own. How far he has succeeded, I leave to the judgment of others. An ape mimics every thing, but does not always succeed. I may appear to many too severe; but let them consider that he counterpart the works of others, and gives them for his own. I venture to assert, that in the future description of his work, he will be careful not to mention the authors whose works he has so unjustly robbed; for he already strives to counterfeit Mr Wilks's plates with what he has copied from others, by reversing the figures, or by giving them a different position." Vol. iii. p. 192. 1749. The substance of these remarks we are sorry to be under the necessity of allowing to be true; for the eye of the artist will perceive, comparing the two publications, that Wilks has taken an unlimited range through the first volume of Rösel. We have repeated the remarks of Rösel at length, because we wish to impress on the public mind the value and importance of any general work, in preference to productions of this nature. Wilks was also publisher of Twelve new designs of Butterflies, in which the insects are disposed in stars, festoons, circles, or other whimsical groups, forming what are usually denominated "butterfly pictures." The nature of the first work above mentioned, is rather incorrectly stated in the title-page; for the plants on which the insects are grouped, are not those which furnish their natural food; they consist of gay flowers, auriculas, roses, monstrous varieties of cultivated plants, fruits, &c. the introduction of which, in preference to their natural food, has incurred considerable censure.

In 1752, Dr Hill, in his History of Animals, published in London in the year 1753, divides insects into three classes: the first Apertia, includes all insects without wings; the second Pieraria, is devoted to the winged insects; the third Gymusotria, comprehends those with soft and naked bodies.

De Geer also in this year, published the first volume of his invaluable work, Memoires pour servir à l'Histoire des Insectes, at Stockholm, which was received with every demonstration of praise to which its merits are entitled. From the testimony of the author's merit afforded by this volume, the continuation was expected with impatience; but nine years elapsed before the second volume appeared, and it was altogether twenty-six years from its commencement to its termination. It was completed in 1778, in which year the labours of its author closed with his life. He was author of several papers in various Transactions, which we shall notice in their proper place.

In this year also, Linné published two dissertations at Upsal, Miracula Insectorum, and Naxa Insectorum. The latter of these is very valuable, from the object in the contemplation of the author; and the first is not destitute of merit.

Scopoli, in the year 1755, published his Entomologia Carniolica, in which he distributes all the insects of which he treats, into orders, genera, species, and varieties, nearly after the manner of Linné. As a systematic work, this publication is of little importance; in other respects it is valuable.

In the year 1754, Kalm, a learned botanist, published a paper on a species of Cicada, in the Swedish language; but we are unacquainted with its title.

In 1756, in folio, Brown's Civil and Natural History of Jamaica.

In 1757, F. Hasselquist Iter Palatinum, eller Resa
In this year, Den Danske Atlas ved Eric Pontoppidan, Kiobenhavn, appeared in quarto. Other parts appeared in the years 1764 and 1767, forming altogether three volumes in quarto.

In 1764, Dr. M. Geoffroy published in two volumes quarto, Histoire abrégée des Insectes, dans laquelle ces Animaux sont rangés suivant un ordre méthodique, Paris.

Linné in this year, again appeared before the public, and produced his excellent Ephasis Museum Lodovici Ulrico Regine. Holmiæ, in octavo.

Also Otho Fr. Müller Fauna Insectorum Fridrichiana siue methodica descriptio Insectorum agri Fridrichsdalensis, &c. Hafniæ et Leipsie, in octavo.

Also J. C. Scheffer's Abhandlungen von Insecten. 3 Banden. Regensbg, quarto.

In this year, J. G. Gleditsch published at Halle, in 8vo, the first volume of Vermiculie Physicall Botan. Economiche Abhandlungen; two other volumes appeared in the two succeeding years.

Also at Copenhagen and Hamburg, Eric Pontoppidan's Kurioerfaste Nachrichten, die Naturhistorie in Danmark betreffend. Also Det Kiobenhavnske Selskabs Skrifter, at Kiobench.

In 1766, Schaeffer published at Regensburg Elementa Entomologica, containing 128 plates, illustrating the principles of his system, and an additional section with two plates, describing the manner of catching insects, and the manner of feeding them, with microscopes, &c. for examining them. He was author of another work on this subject, in the German language, entitled, Zweifel und Schwierigkeiten, welches in der Insektenlehre annoch vornemlich, published at Regensburg in 4to, but we are ignorant of the date.

In this year, also, a second edition of Frisch's work appeared.

In 1767, Pallas published at Berlin, in 4to, the first Pallas' fasciculus of his Specialega Zoologica quibus nova informis et obscura animalium species Iconibus, descriptionibus atque commentariis illustratus, a very valuable work. Several other numbers or fasciculi were published before the year 1780, when the last made its appearance.

And in the same year, the twelfth edition of the Systema Naturae of Linne was produced. As this was the last work of that illustrious naturalist, we shall lay before our readers his entomological arrangement. He divided insects into seven orders, deducing his characters from their wings, as follow:

Order I. Coleoptera, (from κολεόπτερος, a sheath, and πτερος, a wing), including those insects having crustaceous shells or elytra, which shut together and form a longitudinal suture down the back of the insect. In many the whole body (abdomen) is covered by these elytra, in others partially. The coleopterous insects comprehend those commonly termed beetles.

Order II. Hemiptera, (from ἥμι, half, and πτερος, a wing.) These animals have their upper wings half crustaceous and half membranaceous, or of a matter intermediate between leather and membrane. Examples, the bug, the locust, &c.

Order III. Lepidoptera, (from λεπίς, a scale, and...
ENTOMOLOGY.

Insects having four wings imbricated with scales. Examples, butterflies and moths.

Order IV. NEUROPTERA, (from πεταλία, a petal, and πεταλία, a wing.) Insects having four transparent naked wings, reticulated with veins or nerves. Examples, libelleulæ, or dragon-flies, &c.

Order V. HYMENOPTERA, (from χνα, a membrane, and πεταλία, a wing.) Insects with four naked and membraneous wings. Examples, bee, wasp, &c.

Order VI. DIPTERA, (from δί, two, and πεταλία, a wing.) Insects with two wings, as gnats, flies, gadflies, &c.

Order VII. APICER, (from α, without, and πεταλία, a wing.) Includes all insects without wings, as spiders, crabs, lie, &c.

The great perspicuity of Linnaeus's System of Entomology, arose from its author having made choice of the most obvious characters which insects afford for the leading distinctions of his orders. In the construction of his genera, he has taken his characters from the parts of the head alone, paying particular attention to the form, situation, and structure, of the antennæ or horns; these parts being conspicuous in most insects, and so infinitely varied in their appearance, as to constitute, with few exceptions, a permanent distinction. That there are other characters which, in the opinion of later entomologists, are better adapted to the purpose of classification, the reader must be aware; but these, although really preferable, are perhaps too minute to become always useful to the student; yet to the man of science, who is really willing to learn and study entomology as a science, there can be no doubt as to the superiority of the modern systems, although we are really to allow that the characters from the mouth are not so well calculated to further the views of the superficial observer, as those proposed by Linne; the simplicity of his arrangement, the celebrity of his name, and the princely patronage under which he wrote, conspired, with other favourable circumstances, to render the science more universally cultivated, admired, and respected, about his time, than it appears to have been at any former period. No system is undoubtedly due to this great man for his entomological labours; but as we have stated before, when speaking of Aristotle, he is not alone entitled to our commendation for the arrangement he has proposed; we must acknowledge the merits of his predecessors, who wrote under less favourable circumstances, but nevertheless excelled in this department of science; men to whom Linne stands in a very high degree indebted, and without the aid of which it is impossible to imagine the system which now commands our respect. In the works of Aristotle and Pliny, in those of Aldrovandus, Swammerdam, Ray, Willoughby, Lister, and various others, (whose works we have noticed,) we perceive, with some variations, the grand outline on which he has formed his system. It was from these valuable sources that he gained the materials, from which he selected, with profound judgment, and the greatest success, the valuable matter, carefully and industriously separating the dross. The characters of his orders and genera also are to be found in several earlier publications, as are descriptions of several of the species. But he has concentrated these scattered rays of science with so much skill and industry, that we must admit that to him alone the science is indebted for that firm foundation on which it now rests. His style throughout is concise and expressive, but in many instances it is so laconic, that it is impossible even to guess at the animals described.

In 1768, was published in Paris, Boscare Dictionnaire raisonné d'Histoire Naturelle, 4to.

And in the same year, at Leipsic, was published in Seepol, octavo, J. A. Scopoli Anim Historico Naturalis. Also Dr John Berkenhout, M. D. published the Berkenhout, first edition of his Outlines of the Natural History of Great Britain. That portion containing insects is very limited, treating of no more than six hundred species, which are arranged after the Linnean system. Notwithstanding the small number of species enumerated, this little work has tended materially to advance the study of entomology in Great Britain. Since the publication of the above, three or four other editions have appeared.

In 1770, J. R. Forster published, at Warrington, in octavo, A Catalogue of British Insects, a mere list of Latin names, amounting to about 1000 species, the greatest number hitherto enumerated. This was intended as a Prodromus to a general work on the insects of Britain, as we learn from the preface, in which the author offers duplicates in exchange for any not in his collection.

In this year also, D. Drury published a very beautiful work in one volume, containing comprehensive descriptions in English and French, with an index of Linnean names, illustrated by coloured copperplates, entitled, Illustrations of Natural History, wherein are exhibited Figures of exotic Insects, &c. The plates form a miscellaneous assemblage of the more beautiful extra European insects, which the extensive collection of its author afforded. Three years after the publication of the first volume, a second appeared; and the third, which concludes the work as far as it proceeded, appeared in 1782. Besides those figured and described in the three volumes published, the extensive cabinet of Mr Drury contained many choice specimens, reserved as materials for a fourth volume, amongst which were a vast number of curious species, collected in the interior of Africa, and other parts of the world, rarely visited by Europeans, the introduction of which would have rendered this volume, (which was never published,) of much greater interest to entomologists in general, than either of the preceding. We may observe, that Mr Drury's cabinet was one of the most extensive ever made, and is said to have contained, in species and varieties, no less than 11,000 insects, (in his time the largest collection,) which he obtained by transmitting printed directions and instructions, in various languages, for gathering and preserving insects, offering sixpence an insect for all insects, "from the size of a honey-bee upwards." His museum of entomology was disposed of, in London, by public auction, and produced about six hundred pounds. One insect, viz. Scarabaeus Goliathus, (Goliathus magna,) was purchased by Mr Donovan, for twelve guineas and a half, who obtained also all the British insects, (which were very numerous,) collected by Mr Drury, and now enrich his splendid museum.

And in this year also, G. A. Harter's Beschreibung derjenigen Insekten welche Herr D. J. Christoph. Schmeller in ceiexx ausserhalb kampferthafens herausgegeben hat. Regensburg, octavo.

In 1771, John Reinhold Forster published Neuer Forster.

* The crabs and spiders are now considered as constituting two distinct classes. See our article CRUSTACEOLOGY.
EN TOMOLOGY.

History.

Species Insectorum centuria, 1; the avowed purpose of which, as the reader is informed in the preface, was to give descriptions of one hundred insects, not mentioned in the latest work of the illustrious Linne. The insects included are partly indigenous; some are from China, and others from South America. The greater number of these are coleopterous insects, and are arranged after the manner of Linne, except the genera anthribus and cistela, which are taken from Geoffry. We may observe many of the insects seem to have been unknown to Linne, and some few were previously made known to the world, by the works of Scheffer and Drury. This the author was aware of; but as they had escaped the observation of Linne, whose work he was solicitous to improve, it was considered right to introduce them. He was one of those eminent naturalists who accompanied the celebrated Captain Cook in his voyage round the world, and his labours as an entomologist in those times entitled him to respect.

The Manitsiara Plantarum altera generum editionis vi, et Specierum editionis ii. Holmiae, of Linne, in which several insects, not noticed in other parts of his works, are described, octavo, appeared in this year.

Curtis.

In 1772, Curtis published in London a translation of the Fundamenta Entomologiae of Linne, which considerably advanced the study in this country.

Lettsome.

And in the same year, Dr John Coakley Lettsome, published in octavo, The Naturalists and Travellers Companion, giving directions how to collect and preserve all sorts of natural productions. It has since undergone several editions, and may be considered as a very useful book to students of entomology.

Brunnichi.

Also M. Th. Brunnichii Zoolégiae Fundamenta prelectionibus academiae accommodata, Hafnie et Lipsiae, octavo.

Kahn.

In 1773, Kahn published a tract relative to the mode of preserving and catching insects, entitled Kurze anleitung Insetten zu sammeln.

Yeats.

Thomas Pattinson Yeats published Institutions of Entomology; an useful work, being a translation of the Linnean orders and genera, collated with three other systems, namely, those of Geoffry, Scopoli, and Schaffer, together with many ingenious observations, by its translator.

It is particularly defective, however, in the comparison drawn between the systems of Linne and Scopoli, from an event which could not be anticipated. When Scopoli published his Entomologia Carniolica, he coincided very nearly with Linne, in his arrangement; but in a work of his, (soon to be noticed,) he abandoned that method, and adopted another. For an account of the system alluded to, see the year 1777.

Pallas.

In this year, the account of a tour made by the celebrated Russian naturalist Pallas, appeared, entitled, P. S. Pallas Reise durch Verschiedene Provinzen des Russichen Reichs. St Petersburg, which has been rendered into Latin and English.

Hill.

In this year, also, Dr John Hill published a Decade of curious Insects; some of them not described before, shown in their natural size, and as they appeared before the Lucernial Microscope, in which the Apparatus was artificially illuminated; with their History, &c.; illustrated with ten quarto plates, in which the figures are sometimes immensely magnified, and far from correct. The scientific accounts are given in English, accompanied with various interesting observations as to their natural history and economy.

Wilks.

In the Transactions of the Entomological Society of London, vol. i. part 1. the work of Benjamin Wilks is stated to have been published in this year, but is noticed by us as having been published in the year 1749, or earlier: but, from the comments made on that work by Rosel, it must have been published, as we have stated, in or before 1749.

In 1774 was published at Amsterdam, in folio, by L'Admiral Jacob L'Admiral, Veranderingen van Veele Insecten.

Also, at Halle, in 8vo. Der Naturforscher, but the author's name not known to us.

And, in this year, Iwan Lepechius Tagebuch der Tagebuch.

Reise durch verschiedene Provinzen der Russischen Reichs; Altenburg. One volume appeared first, and two others before 1783.

In 1775, an interesting little work, describing the insects of Switzerland, under the title Verzeichniss der ihm Bekannten Schweizerischen Insecten, was printed at Zurich, in quarto, by Joh. Gaspar Faeslin.

In this year, J. C. Fabricius, a pupil of Linne, published a new system of entomology, under the title Systema Entomologie, in which the principles of a new mode of classification is for the first time developed. He has taken the essential characters of the classes (orders, Linne would have termed them) from the parts of the mouth (Insecta cibaria), which has given this the title of Cibarian System. He, in this work, divides insects into eight classes, viz. Eleutheria, Ulonata, Synistata, Agonata, Uognata, Glossata, Rhyngota, and Antliata. In this part of his system he has been followed by very few; but his mode of distinguishing the genera is still retained, and opens the way to the knowledge of natural genera, which, by his method, are generally to be distinguished without examination of any other parts.

As he has since that time written several other works, and added considerably to this system, we shall defer noticing it further for the present. We may, however, observe, that he gained such reputation from this work, that he was induced to prosecute his entomological studies with increased ardour, and during his lifetime always held the highest rank as an entomologist.

Also, Descriptiones Animalium, Arvin, Amphihilorum, Forskal. Pictured Insectorum, &c. quae in Hinere Orientali observavint, Petrus Forskal, Prof. Harn. Post mortem Auctoris, edito Carsten Niebuhr; Havnæ, quarto.

Moses Harris also published a little pamphlet, entitled The English Lepidoptera, or Aurelian's Pocket Companion, &c. London; an alphabetical catalogue of the larger lepidoptera collected by its author in England. This little tract, although apparently insignificant, has materially contributed to the practical study of entomology. The Linnean names, as far as they were known to him, with the time and place of the appearance of the insects, in both states, are concisely given in columns. A frontispiece is added, explaining the terms used in the description of animals of this order.

In 1776, Peter Brown figured a number of insects in Brown's New Illustrations of Zoology.

In this year, Sulzer published, in quarto, Abge-Sulzer, kürzeste Geschichte der Insecten, Winterthur.

The Genera Insectorum of Fabricius appeared in this Fabricius year.

In this year, also, J. H. Sulzer's Abgekörnter Geschichte der Insecten, 2 Theile, quarto.

In this year, O. F. Müller Zoologie Danzics Prodromus, &c. Hafnia, appeared in octavo, and must ever be considered a most valuable and useful work.
In this year was published at Halle, in octavo, the first part of a work, entitled, Joh. Schröter Abhandlungen über verschiedene Gegenstände der Naturgeschichte; a succeeding part appeared in 1777.

In 1777, Seopoli published the systematic work before alluded to, under the title, Introductio ad Historiam Naturalum. In this work (which does not relate exclusively to the science of entomology), he divides insects into five tribes, under the singular appellations of Swammerdami-haufen, Geoffroy-gymnoptera, Röselli-lepidoptera, Remurrii-prosoidae, and Frischii-coleoptera. In this manner he identifies each tribe with the name of that author who has, in his opinion, been most successful in the explanation of that to which his name is attached. The order Lusifaga includes two genera, 1. Crustacea, 2. Pedicularia. Gymnoptera comprehends his Halterata, Acalata, and Caudata. Lepidoptera, the genera Spinix, Phaenix, and Papilio. Proboidea, he divides into terrestrial and aquatic. And the Coloptera he divides likewise into those inhabiting water, and those the land.

In this fertile year, J. A. E. Goeze began to publish an extensive systematic work called Entomologische beiträge zu des Ritters Linnei zörflichen Ausgabe des Natur- systems, &c. which was continued progressively in parts till 1783, in octavo.

Esper also produced in Germany the first part of his valuable work on lepidopterous insects, entitled, Die Schmetterling in Abbildung nach der Natur mit Beschreibungen, accompanied by many plates, of which a second part was published in 1779. Between that time and 1786, two other parts appeared likewise, and which, altogether, form a very extensive publication.

In 1779, at Berlin, was published in quarto, by Peter Simon Pallas, Naturgeschichte Merkwürdigen Thiere, in welcher Vornehmlich neue und unbekannte Thierarten durch künstliche, Beschreibungen und Erklärungen erläutert werden.

And Paul Czempinsky published, in octavo, Totius Regni Animalia Genera.

Also, Magazin für die Liebhaber der Entomologie Herausgegeben, von Jos. Caspar Fuesly, Zurich and Winterthur.

And, in this year, at Leipsic, in octavo, was published, Versuch einer Naturgeschichte vom Liedland, entworfen von J. L. Fischer.

Moses Harris also published his Aurelian, or Natural History of English Insects, namely, Moths and Butterflies, London, in quarto.

Lastly, J. C. Fabricii Philosophia Entomologica, &c. a work to be studied by every scientific entomologist.

In 1779, Pieter Cramer published, De vit Landisc Hence capellen, Voorkomende in de drie Wercrub deelen Asia, Africa, en America, or extra European insects, which, with the continuation published in the year 1782, consists of four volumes in quarto, with many plates, confined entirely to lepidopterous insects.

And, in the same year, another very expensive work, in the French language, named Papillons d'Europe, points d'après Nature, which, as its title shews, is devoted entirely to the lepidopterous insects.

In 1779, was published, in octavo, Anfangs-gründen der Naturgeschichte, von Nath. Gottl. Leske. Leipsic.

In 1780, in Berlin, was published, in octavo, Schriften der Berlinischen Gesellschaft Naturforschenden Freunde.

Also, Otho Fabricii Fauna Geographica, &c. Haf., oboine et Lipsia; a valuable little work, in one volume Fabricius, octavo.

In 1781, was published, in London, by James Barbat, but, an elementary work, The General Insectorum of Linnaeus, exemplified by various Specimens of English Insects. As an illustration of the Linnean system, this work may be not uninteresting to the English reader, but his views are too limited to admit of even more general utility. Its author does not seem to have been aware that most improvements in the science had undergone in the Continent, in the interval between the publication of the General Insectorum of Linne, and the time in which he wrote; and has therefore drawn no comparisons between them, which, without innovation, must have placed the science in a more lucid point of view. It is to the silence of English writers in this respect, arising either from want of information, from sentiments of illiberality, from jealousy, or negligence, that we must ascribe the very low state of entomological knowledge in Britain, even to the present period.

In the same year, Franciscus Paula Schrank distinguished himself by his enumeration of the insects of Austria, called Enumeratio Insectorum Austriaca Indigenerorum, which has since been rendered into German by Fuesly.

Johann Nepomuk von Laicharting, in this year, published, at Zurich, the first part of his catalogue of the insects of the Tyrol, Verzeichniss und Beschreibung der Tyroder Insecten; a second part appeared in 1784. He adopts a system distinct from that of Linne. Insects by him are divided into ten classes or orders, characterised from various parts of the body. These orders are named, Sisaraboides, Gryllidés, Cimicoides, Papilionoides, Libelluloides, Vespoides, Muscidés, Cancrioides, Araneoides, and Ondisidés.

In this year, the Icones Insectorum præsentis Ross, Siberia, peculiarium, que Collegii et Descriptionibus illustravit, Petrus Simon Pallas, M. D. Erlanger, appeared in one volume quarto.

In this year, Niclaus Joseph Jacquin published, in quarto, Miscellanea Austriaca, oder Botanicae, Chemiae et Historiae Naturalis.

Also, the Genera Insectorum of Linneus, &c. by James Barbat; London, quarto, another edition.

And Thunberg published at Upsal, Ejusdem Museum Naturalium Academia Upsalensis, &c. Pars 1; to which twenty other parts, and an appendix, were added before the year 1800.

Also, Beitrage zur Insectentheoriegeschichte von August, &c. Knoch, Wilhelm-Knoch; Lipsig, octavo.

And J. C. Fabricii Species Insectorum, appeared in the same year.

In 1782, Moses Harris published his Exposition of English Insects, &c. illustrated by fifty-one copper-plates, in quarto, in which he has given figures of about 500 species. The text is in French and English, and the specific names are given in Latin, but many such as can never be adopted; such as, for example, (Apis) Audra, &c.

And in quarto, Eric Pontoppidan Det første Forsog pa Norges Naturlige Historie, Kjöbenhavn.

In the Transactions of the Paris Academy, for this year.
year, we find a paper by Morand, entitled, *Memoire sur les Vers de Truffes, et sur les Mouches qui en proviennent.*

J. S. Semler also published, in the German language, under the title *Versuch eines Diarium über die Ökonomische Mancher Insecten im Winter.*

Semler.

Fuesly.

A Part of the Encyclopädie Methodique, comprehending *Historie Naturelle des Animaux,* was published in Paris this year.

Retzius.

In 1783, Retzius produced his *Genera et Species Insectorum,* in which the method of De Geer is simplified, and the terminology of Linne is partly adapted to that performance. He divides insects into fourteen classes, under the titles, Lepidoptera, Aliningia, Neuroptera, Hymenoptera, Siphoniata, Dermaptera, Hemiptera, Coleoptera, Halerata, Prosoidea, Suctoria, Ancipata, Atrechelia, and Crustacea.

In this year, a tract on the Aphides (plant-lice, or puceron,) appeared, entitled, *Nachlese zur Bonnischen Insectologie.*

Curius.

And W. Curtis published an interesting little pamphlet, *A short History of the Brown-tail Moth,* the larvae of which appeared in such immense swarms in the fields surrounding London, during the summer of 1782, and despoiled so many trees of their foliage, as to create apprehensions of the total destruction to the whole vegetable tribe. The object of this tract was to show, that grass, not being the food of these voracious animals, would escape their attack. This is an additional proof, that some benefit at least may result from an acquaintance with the natural history of insects; for the author, by this publication, was enabled to dispel the uneasiness occasioned by those supposed "ministers of famine," and which prevailed to such an alarming extent throughout the whole population of that vast metropolis, that prayers were ordered to be read in all the churches to avert the supposed impending calamity.

And the following work, which we have never seen, but understand to be a valuable publication, *Abhandlungen der Hallischen Natur-forschenden Gesellschaft,* Dessau and Leipzig, in octavo.

Retzius.

Also, the interesting work by Baron De Geer, *Genera et Species Insectorum, curante, A. J. Retzius,* Lipsia, octavo.

Bergstrasser.

In 1784, an elementary work, in octavo, entitled, *Entomologia Sociorum in usu Cincinnati,* was published by J. A. Bergstrasser.

Thunberg.

Thunberg, in this year, published his *Disseratio Sistens Insecta Sueciae.*

Harrer.

And, in the same year, Harrer wrote on the insects of Germany; under the title, G. A. Harrer's *Beschreibung Derjeniger Insecten welche Her D. I. C. Scheffer, &c. at Regensburg,* in octavo.

Herbst.

Herbst also produced his work, entitled, *Kurze Einleitung zur Kenntniss der Insekten,* Berlin, octavo.

Laicharting.

Laicharting published at Zurich, *Johan Nepomuk von Laicharting Verzeichniss der Tyrolder Insecten,* 2 tom. octavo.

Fourcroy.

*Entomologia Parisiensis, sive Catalogus Insectorum que in agro Parisiensis reperiuntur, Secundum Methodum Geographiam, &c. edente A. F. De Fourcroy,* duodecimo, in two volumes.

Martyn.

Matthew Martyn's *Aurican's Vade Mecum,* &c. was published in Exeter. The insects are whimsically ar-

ranged, according to the Linnean classes and orders of plants on which they feed.

*Historia Naturalis Curacionum Succisae; autore Bonstorf.*

Gabriel Bonstorf, &c. Upsal; in quarto.

In 1786, Xavier Walfen published an account of the waflen, insects inhabiting the Cape of Good Hope.

Seopolii Deliciae Flora et Fauna, &c. Ticiini, in folio.

In 1787, were published the following works:

By Dominicus Cylliurus, a folio work on the insects of Naples, entitled *Entomologia Neapolitana.*

A curious little tract, on the gad-fly, was published in Leipsic, by J. S. Fischer, entitled *Observationes de Oestro ovinio atque bovino fatoct.*

Fabricius printed his *Mantissa Insectorum,* &c. Hafniae, in two octavo volumes.

Vincentii Petagna *Specimen Insectorum Uterioris Petagna,* Calabria, Francofurti et Moguntiae.

In 1789, a series of letters on the important subject of the cochinel insect, (which had been discovered at Madras a few years before,) from James Anderson, addressed to Sir Joseph Banks, from Madras were published. Two other letters on this important subject have been published since.

And in the same year Swedener published a monograph on that curious and interesting genus Cerapterus, in a memoir entitled *Bestriifung poa eli nytgen ibland insekterna, hörande till Coleoptera.*

The work of M. B. Borkhausen, treating of the lepidopterous insects of Europe, part 1. appeared at Franconia; fort, under the title *Naturgeschichte der Europaischen Schmetterlinge nach Systematischer ordnung.*

J. F. Guelin published his edition of the Linnean Guelin. *Systema Naturae.* The entomological part is comprised in three parts, and was published in Leipsic. The editor is considerably indebted to the writings of Fabricius; and although he rejects his classification, yet he has copied the species, and incorporated them with the Linnean genera, which he has divided into families answering to the Fabrician genera, and has, by this means, very materially augmented and improved the original work of Linne; although we must allow that he has committed a vast number of the most inexcusable blunders, especially in his quotations and references to plates. He has also, in many instances, described the same animal twice, or three times, under different names. We are surprised that his errors are less numerous, as he can be esteemed in no other light than as an industrious closet compiler.

In this year, also, was published, in Leipsic, octavo, Goze.
Two works, by Scriba, were also published in this fertile year, _Begriffe zu der Insekten Geschichte, Herausgegeben von Ludwig Gottlieb Scriba_, Frankfurt, in quart, part the first; and _Journal für die Liebhaber der Entomologie, Herausgegeben von L. G. Scriba_, Frankfurt, in octavo.

Lastly, a work which we scarcely consider as worthy of notice, is _entitled the Naturalist's Miscellany_, or, as it is also termed, _Vitrum Naturae_, by G. Shaw; the figures by P. Nodler. It contains a variety of daubed, (or, as they are termed, coloured) figures, of the more beautiful and larger exotic insects, as well as other animals, with descriptions extremely suitable to the general class of readers, (children,) for whose purpose, we conjecture, it was designed by its author, who, with greater advantages than any other naturalist in this country, has produced this publication, which, we are sorry to state, reflects the greatest disgrace on the class of readers who could give encouragement to so contemptible a performance. We notice it, as we perceive it quoted by children, who, (with such a work as the author might have given to the world,) would very probably be induced to bestow some attention to the study of natural history, so much neglected in this country.

In 1791, a year which produced several valuable entomological works, Meyer published a work which we have noticed under the year 1790, whilst speaking of another of his works.

The first volume of the _Transactions of the Linnean Society of London_ was published in London, containing a paper on _Phalana Bombyx lubricopedus_ of Linne, and some other species allied to it, by T. Marshall, Esq.; some observations on the natural history of _Cureutilo Lapalii_, and _Sphila grisen_ of Linne, by W. Curtis, Esq.; account of a singular conformation in the wings of some species of moths, by Esprit Giorna of Turin; and descriptions of two new species of _Phalena_, by Louis Bosc of Paris: lastly, under the head of extracts from the minute book, we find mention of a new _Buprestis_, communicated by Mr Dryander.

In the same year, _Neuestes Magazin für die Leibhaber der Entomologie_, herausgegeben von D. H. Schneider 5 hefte. Stralsund, in octavo.

Also an interesting work on some of the _Hymenoptera_, entitled, _Naturgeschichte, Klassifikation, und Nomenclatur der Insekten von Bienen, Wespen, und Amestengeschicht_. Frankfurt am Main, quarto, by Christian Johannes Ludwig.

In the year 1792, several valuable works were produced, and amongst others, the first part of a very considerable work, _the Natural History of British Insects_, by Edward Donovan, which has since been continued to monthly numbers until the present time. The design of this immense undertaking is to afford general and scientific descriptions of all the insects of Great Britain, accompanied with a coloured figure of each, as far as possible in their various states of transformation. The work at this time consists of eighteen volumes, and includes an extensive variety of the species, being the most extensive work hitherto undertaken as an elucidation of the Entomology of Britain. It is in octavo, and still continues to appear in monthly numbers.

Thomas Martyn published in this year, in imperial Martyn, quarto at London, _The English Entomologist_, exhibiting all the coleopterous insects found in England, including upwards of five hundred different species, the
Figures of which have never been given to the Public; the whole accurately drawn and painted after nature, arranged and named according to the Linnean system. The figures given in this work are useless, and its press is but indifferent.

Fabricius in this year published his Entomologia Systematica; a supplement appeared in 1798, under which head we shall notice his system.

Paykull also, whose name we have often noticed, produced his Monographia Curculionum Suecic; a species of writing which has tended more than any other to the promotion of natural history.

In 1793, the Eujudem Beyträge zur Geschichte der Insecten, Erlangen of Panzer, appeared, who in the same year began his most interesting work in monthly numbers, entitled Fauna Insectorum Germanica. iter, oder Deutschland Insecten, auctore W. F. Panzer, which still continues to be published.

Dr Smith's Tour on the Continent in 1786 and 1787, appeared in this year. It contains some interesting remarks on the insects which occurred in his journey.

Also an interesting work in 4to, entitled, Nomencla tor über die in den Täüischen Insecten beobachtungen und Kleinenischen Beobachtungen zur Insectengeschichte abgebilliten und beschrieben Insecten und Würmer mit möglichst vollständiger Synonymie. Erste Abtheilung. Nürnberg.

In 1794, a second volume of Linneus Transactions was published, in which are the following papers: the history and descriptions of four new species of Pholade by Mr J. Beckwith; a new arrangement of the genus Papilio of Linné, by W. Jones, which is so interesting, as coming from such excellent authority, that we cannot refrain from laying before our readers an account of his innovations. The object of his paper was, to point out that the shape of the wings, (which forms a principal character with Linné in his distribution of the families of that genus,) though various at first view, approach each other so gradually, that it is impossible to draw them the distinguishing line between each family. Linné, he observes, was acquainted with about 274 species, whereas the writer of this memoir states, that he had seen above 1000 in different cabinets, and about 400 more in various publications; and from an attentive examination of these, is induced to offer the following amendments to the characters of each of the Linnean families. Linné describes the Equites as having "the upper wings longer from the posterior angle to the point than to the base; antennae often filiform." He corrects the character thus: "Upper wings longer from the posterior angle to the point than to the base, occasioned by having four instead of three nerves, visible in every other family. The palpi often a brush; under wings, with a connecting nerve in the centre, and without an abdominal groove." — Heliconia: "Wings narrow, entire, often naked, or deprived of scales; upper wings long; under ones short." Linné. To this character is added, that the upper wings have "a connecting nerve in the centre, very slightly grooved to admit the abdomen, which, with the antennae, are generally long." — Danae: "Wings entire." Linné. To which Jones adds, "the under wings, with a connecting nerve in the centre, and a deep abdominal groove; palpi projecting." — Nymphalus: "Wings denticulated." Linné. Jones adds, "under wings without a connecting nerve in the centre, with a deep abdominal groove; palpi projecting." — Plebejus: "Small rufipes; spots on wings obscure." Linné. Jones adds: "Thorax and abdomen slender; under wings without a connecting nerve; antennae clubbed; and these he divides into two sections, those with long, weak, flexible tails; and those without tails, and having the wings entire. — Plebejus urbicola: "Spots on the wings generally transparent." Linné. Mr Jones divides these into three sections, thus: 1. Thorax and abdomen short, thick or broad; under wings without a connecting nerve; antennae hooked at their points. 2. Upper wings pointed at their extremities, and long in proportion to their width. 3. Upper wings less extended, and, together with their under wings, more round; their margins entire. — To the Linnean families, Mr Jones adds another, which he terms Romanist, which are generally of a large size, without the abdominal groove; no connecting nerve; antennae generally sharpened; and the nerves in both wings extending from their base to their extremities nearly in straight lines. We cannot conclude our account of this ingenious arrangement, without observing, that Mr Jones has made a series of drawings for the gratification of himself and friends, of every species which he could obtain to, in a very elegant and correct style.—In this volume Mr Marwick has given an account of Gmelin's Musca Pumiliana, to which some ingenious remarks are added by Mr Marshall.

In this year Archives de l'histoire des Insectes publiées Fucely, en allemand, par Jean Gaspar Fucely, traduites en Francais. Winterthur, in 4to.

Panzar also published Fauna Insectorum Americae Panzer. Borralis prodomus. Norimburgae, in 4to. who also edited the following work:

In 1793 was published at Halle, in octavo, Entomologisches Bilderbuch für junge Insektenansater, von Johann, Heinr. August, Dunker.

William Lewin published this year, The Papilios of Great Britain in quarto; in which he describes in English, with very elegant figures, all the species of butterfly at that time known to inhabit those islands, which amounted to about sixty. We understand that the author intended to have figured all the Lepidoptera of Britain; but his untimely death prevented his proceeding farther than the Papiliones.

Latreille in this year produced his Precis du Charactere des Genres, in which he divides insects into two sections, viz. those with and those without wings, and these he divides into the following orders: Coleopteres, Orthopteres, Hemipteres, Neuropteres, Lepidopteres, Saccures, Thysanures, Parasites, Acéphales, Entomocramés, Crustaces, and Myriopodes; as he has completely altered this arrangement in his later works, we shall omit noticing this method farther, as it will be sufficiently obvious to the reader what these alterations are from the terms employed, &c. A new edition of Rossi's Fanno Etrusco, &c. was pub. Rossi.
Mr. Francillon published a small tract on a new coleopterous insect, accompanied with a coloured figure. It is entitled, Description of a rare scarabaeus, from Potosi in South America; with engraved representations of the same, coloured from nature. Scarabaeus mucropus is the name applied to the singular insect.

In 1795, was published Insecto-Theology, or a Demonstration of the Being and Perfections of God, from a consideration of the Structure and Economy of Insects. This is a translation of Lesser's work, mentioned before under the year 1742, with Lyomnet's notes, and a few others by the translator. Lond. 8vo.

In 1796, appeared Sammlung naturhistorischer und Physikalischer Aufsätze von Frans von Paula Schrank, Nürnberg. In octavo.

And an interesting work in folio, Museum Regium descriptum ab Oligero Jacobico. Hafn.

Hübner published his Der Sammlung Europaischer Schmetterlinge, Ausburg, in quarto. But few copies of this beautiful work have reached this country, and as we have not examined it with care, must refrain from giving our opinion on it. From what we have seen, it appears to be a valuable publication.

The second volume of Catalogus Bibliothecae Historicae naturalis, Josephi Banks, Baronet, by T. Dryander, comprehending the entomological works of that immense collection of books, was published in 1796. We cannot speak too highly of its contents, which are admirably arranged, in such a manner as to be in itself a valuable bibliothecal system of entomological writers.

In 1797, C. W. Hennert published at Berlin a work in quarto, entitled Ueber den Raupenfuss und Winbruch in den Jahren.

And Dr. J. E. Smith published a magnificent work in folio, in London, entitled The Natural History of the rarer Lepidopterous Insects of Georgia, collected from the Observations of Mr. John Abbott. It is comprised in two volumes, with about an hundred plates; and the insects are represented in their different states, on one of the plants on which they feed. Mr. Abbott, the gentleman from whose notes and drawings the work was formed, was an assiduous collector of insects residing in North America, from whom many of the London cabinets have received the most valuable specimens of the insects of those regions, in the highest state of preservation.

In the same year, Mantissa Insectorum Iconibus illustrata, Species novas aut nondum depictas exhibens, fah. 1, auctore, Godofredo Christiano Reich, &c. Nürnberg. In octavo.

The third volume of the Transactions of the Linnean Society of London, containing some interesting entomological papers, appeared, as follows: Observations respecting some rare British insects, by W. Lewin;—a History of three Species of Cassida, by the Rev. William Kirby;—Observations on the Economy of Ichneumon Manifestor, by Thomas Marsham, Esq.—Observations on the Insects that infested the Corn in the year 1796, by Thomas Marsham, Esq.—Lastly, a most interesting and curious paper on the Oestrus, or Gad-fly, by B. Clark, Esq.

In 1798, Fabricius published the supplement to his Entomologia Systematica; which presents an outline of his system in its latest state; and being the result of such extensive knowledge as he possessed, demands a considerable share of our attention. He, in this work, divides insects into thirteen classes, as follow:

Class 2. Ulonata. Jaws covered with an obtuse galea or mouth-piece.

Class 3. Synistata. Jaws elbowed near the base, and connected to the lower lip.

Class 5. Odonata. Jaws horny and toothed; two palpi or feelers.

Class 8. Polygynata. Jaws many, (generally two) within the lip.

Class 10. Exochinatha. Jaws several, outside the lip, but covered by the palpi.

Class 11. Glossata. Mouth composed of a spiral tongue, situated between the two palpi.

Class 12. Rhynogota. Mouth composed of a beck, or articulated sheath.

Class 13. Antlata. Mouth composed of a sucker, not jointed.

In the same year, viz. 1798, Clairville published an octavo work on the insects of Switzerland, in which he proposes to divide insects into eight orders, nearly after the system of Linne; but he distinguishes them by different names, and denominates them sections instead of orders. The names are, Elytroptera, Dipterygoptera, Phlebopera, Heliptera, Lepidoptera, Hemicycopera, Raphopera, and Pododonera. The work is entitled, Entomologie Helvétique, ou catalogue des Insectes de la Suisse, &c. Avec descript. et figures. Zurich.

In the fourth volume of the Linnean Transactions, we find, an Essay on the Eye-like spot in the Wings of the Locust of Fabritius, as indicating the male sex; by Professor Anthony Augustus Henry Lichtenstein;—Account and Figure of a minute Ichneumon; by G. Shaw, M. D.—Amophilia, a new genus of Hymenoptera insects, including the Sphinx sabulosa of Linne; by Rev. William Kirby.—Further Observations on the Wheat Insect, in a Letter to the Rev. Samuel Goodenough, by T. Marsham, Esq.—History of Tipula Trichi, and Ichneumon Tipulæ, with some observations upon the Insects that attend Wheat; in a letter to Thomas Marsham, Esq. by the Rev. William Kirby;—Observations on the genus Parnass, and Description of a new Species; by Adam Auzelius, M. D.

E. Donovan this year published in London, Natural History of the Insects of China, which is the first work on the entomological productions of that vast empire that has appeared. The materials composing this volume, (which is in 4to.), and from which it was in a great manner formed, were obtained from the first and most authentic sources, including many of the species collected at the time of the embassy of Lord Macartney, with many others obtained from the cabinets of the highest celebrity, and the communications of friends. The work is illustrated by fifty copper-plates, beautifully coloured. It has been translated into the French and German languages on the continent.

Pamela Linnaeus Prodromus, exhibens methodicam Descriptionem Insectorum agri Petropolensis, &c. auctore J. Cederlehn, Leipsic.
History.

And Verzeichniss der Käfer Prussens enthalten von
Johann Gottlieb, von Johann Karl Wilhelm Illiger, &c.
Halle, in 8vo.

Gottlieb,

Webersicht.

Also Buech Webersicht, (Almanack) der fortschritte
in Wissen. Erfurt, in 8vo.

Zinke.

Likewise, Naturgeschichte der schädlichen Nadelholz-
Insekten, nebst Anweisung zu ihrer Vertilgung; (Ein
nützliches Lesebuch für Naturforscher, Forschsmänner
8vo.

Voigt.

Voigt, in this very fertile year, published his Maga-
zin für den neuesten Zustand der Naturkunde mit Bünck-
richt auf die dazu gehörigen Wissenschaften. Von

Schrack.

Schrack also published his Fauna Boica Durchge-
dachten Geschichte der in Bayern einheimischen und Zah-
men Thiere. Nürnberg, in 8vo.

Paykull.

In the same year, Paykull published his valuable
work on the insects of Sweden, entitled, Gustave
Paykull Fauna Suecica, Insecta, Upsalia, in three oc-
tavo volumes.

Goeze.

In 1799, a very useful work, entitled, Europäische
Fauna oder Naturgeschichte der Europäischen Thiere.

Cratzer.

And Christian Cratzer Entomologische Versuche.
Wien, in 8vo.

In 1800, the science of entomology was consider-
ably advanced, by a vast number of very valuable
works.

Curvier and

Dumeril.

Curvier, with the assistance of Dumeril, published in
Paris his Anatomie Comparée, in which the organiza-
tion of insects is treated of at great length, and a new
systematic arrangement is proposed, and insects are
divided into two great sections; those with, and those
without, jaws. In the first, are included the orders
Gnathopterae, Neuropterae, Hymenopterae, Coleopterae,
and Orthopterae; in the second, Hemipterae, Lepidop-
terae, Dipterae, and Apertae.

Thunberg.

In this year, Thunberg published his Museum Nat-
uralium Academiae Upsalensis, &c. in 4to.

Donovan.

And E. Donovan published his Insects of India, in
4to; and, like the Insects of China, embracing in a ge-
eral, yet scientific view, a comprehensive display of
the most rare and beautiful insects peculiar to those fer-
tile regions.

Wallner.

Also Wallner’s Forschzygographische Herborn, &c.

Wiedmann.

In the same year Archiv für Zoologie und Zootomie.
Von C. R. W. Wiedmann. Berlin and Braunschweig,
in four octavo volumes.

Sturm.

And the Verzeichniss meiner Insekten Sammlung oder
Entomologieisches Handbuch für Liebhaber und Samler.
Von Jacob Sturm, Erste Heft. Nürnberg, in 8vo.

Dryander.

Lastly, the 5th volume of Bibliotheca Hist. Nat. Bank-
sians, by Dryander, contains some references to the
works of entomological writers.

Lamarck.

In 1801, a most interesting publication appeared in
Paris, by the celebrated Professor of Zoology, Lamarck,
etitled Systeme des Animaux sans Vertèbres, in which
we find considerable improvements in the entomologi-
cal department. He removes the greater number of
the Linnæan apertae to other classes, viz. CRUSTACEA
and ARACHNIDES. See our article CRUSTACEOLOGY.
The INSECTA he divides into three subclasses: 1. Those
with mandibles and maxillae; 2. Those with man-
dibles and trunk; 3. Those without mandibles, but
having a trunk or sucker. In the first, he places the
orders COLEOPTERAE, ORTHOPTERAE, and NEUROPTERAE; the
second is merely confined to the HEMIPTERAE; and in
the third, the LEPIDOPTERAE, HEMIPTERAE, DIPTERAE, and
APERTAE, (which last contains but one genus, viz. Pulex,
the flea). His subdivisions of the orders we shall have
occasion to notice hereafter at length.

Fabricius also published his Systema Entomologorum Fabricius.
Kilje, in two octavo volumes.

And Illiger produced his Magazin für Insektenkunde Illiger.
herausgegeben von Karl Illiger. Braunschweig, in
octavo.

Likewise Neue Beiträge zur Insektenkunde. Von Knoch.

Another interesting work, Frederick Weberi Observa-
tiones Entomologicae, continentes novorum, qua condi-
dit generum characteres, et nuper detectarum Specierum
descriptiones. Kiel, octavo.

Lastly, Jacob Sturm’s Abbildungen zu Karle Illiger’s Sturm.
Ueberfertigung von Olivier’s Entomologie oder Naturges-
chtie der Insecten. Nürnberg, in quarto.

In 1802, several works appeared in this country, and
two in Paris, highly interesting, especially to the natu-
ral systematist. We may first notice Histoire Naturelle
des Fourmiers, et recueil des Ménaires, et des Observations
sur les Abeilles, les Araignées, les Franchois, et autres

The Rev. William Kirby this year produced that ex-
cellent work, entitled, Monographia apin Angliae, &c. in
two octavo volumes. Our author proceeds to point out
his reasons for taking up this subject, and under the
head of Introductory Remarks, gives us a minute ac-
count of the rise and progress of this department of
entomology, with remarks on the various works treat-
ing on this subject, with definitions of the terms used
in describing the genera and species by different au-
tors; and after pointing out the confusion which
reigned throughout the order Hymenoptera, gives us
a new set of terms, with comments on terminology in
general. The characters of the order Hymenoptera,
with the generic characters and divisions of families,
are next given, intermixed with the economy of each
family and subdivision. Under the head of Addenda,
we have some interesting remarks on other hymeno-
pterae genera; and at the end of the first volume, a se-
ries of plates explaining the various parts of the mouth,
&c. peculiar to each family and subdivision. The se-
cond volume treats of the species, with occasional re-
marks on the peculiar economy of each. The descrip-
tions are laboured, and extremely accurate. It is cer-
tainly the most scientific work which has appeared in
any branch of natural history in this country. In the
work of Latreille, which we have mentioned above,
we find the same divisions as those instituted by Mr
Kirby; they differ merely in terms, Latreille consider-
ing each of Mr Kirby’s subdivisions as a distinct gen-
us. We wish we had room to give a complete account
of this interesting publication, but we have already far
exceeded our limits in this department of the article,
and shall therefore lay before the reader as much of
that valuable work as we can find room for, under the
proper head, in our descriptions of the species.

Thomas Marsham, Esq. the oldest of the British en-

vol. ix. part 1.
entomologists, this year published the first volume of his long intended work on entomology. This volume treats of the coleoptera, and is entitled, *Entomologica Britannica*. To the genera of Linnaeus, he adds, Cetida, Corticaria, Nitidula, Bolitaria, Opatra, CRYPTOCEPHALUS, Auchenia, Croceoris, Tellus, Seophilum, Clerus, Pyroglastra, Parnas, Heterocerus, Blaps, Lyget, Ips, and Hydrophila; the two last, however, are to be found in the MSS. of Linnaeus. We cannot approve of this author having changed the names of some of the genera, and using them in a different sense from other authors, and in sometimes unnecessarily giving up one name, and imposing a new one: thus we have Bolitaria for Mycaephagus, and Corticaria for Lyctus, Ips, and Colisium. In his descriptions he is very accurate; and although he has not adopted all the Fabrician genera, yet in many instances his families are composed of the same materials. We anticipate the completion of his work with great pleasure, as the abilities of the author are universally acknowledged, and his collection and manuscripts extremely valuable.

The sixth volume of the Transactions of the Linnean Society of London, which appeared this year, contains several valuable entomological tracts, viz., "A Dissertation on two natural genera, hitherto confounded under the name of Mantis; by Anthony Augustus Henry Lichtenstein, M.D. &c."

"Observations on Aphis, chiefly intended to shew that they are the principal causes of the blight in plants, and the sole cause of the honey-dew; by W. Curtis." "Observations on the Curculio Trifoli, or clover-veevil, a small insect which infests the heads of the cultivated clover, and destroys the seed, in a letter to T. Marshman, Esq. by William Marshall, Esq.; with additional remarks by Mr. Marsham." "Further remarks on the Curculio Trifoli, in a letter to William Marshall, Esq.; by Martin Christian Gottlieb Leilmann." "Descriptions of some singular coleopterous insects; by Charles Schreiber." "Observations on several species of the genus Aphis, known by the name of humble bees, and called Bombinieces by Linneus; by P. Huber." This last paper is extremely valuable; and, with the others, will be mentioned when we are treating of the genera and species.

This year, an anonymous work, in 2 vols. 8vo., appeared at Edinburgh, under the title of *Elements of Natural History*. It is a very useful elementary book, and does credit to the author, who, it is well understood, is Mr. Charles Stewart of that place. The first volume treats of mammalia, birds, amphibia, and fishes; the second volume is entirely dedicated to insects and vermes. It is now out of print; and we may suggest, that if a new edition were altered to suit the present systems, it would prove still more valuable and interesting to the student of natural history: we may be excused for adding, that several species of insects are marked as natives of Britain, which have not been admitted as such into the best British collections—a slight mistake, but one which is calculated to embarrass the beginner, and may easily be avoided in future.

In the same year, Faune Parisienne (Insectes) ou Histoire abrégée des Insectes des environs de Paris, classés d'après le Systeme de Fabricius, &c. Par C. A. Walckenaer, tome première.

And Entomologische Beiträge. Von J. R. Schellenberg. Winterthurer, 4to.

In 1803, A. H. Haworth presented us with the first part of an elaborate work, entitled, *Lepidoptera Britannica*, the object of which is, as we are informed in the preface, to give descriptions of the various species of that beautiful order of insects which are natives of this country. The task is a very difficult one, being perhaps the most difficult of all the orders; at least in describing the species, the entomologist will find himself more perplexed than in his examinations of any other. The author has acquitted himself, in our opinion, with considerable credit. Two other parts have since appeared, but the work is incomplete, one part being still unpublished.

In this year also appeared *Versuche über die Insekten*. Schmid. Ein Beitrag zur Verbreitung des Nitzschien und Wissenwürdiges in der Insektenkunde; von Carl August Schmid. Gotlha. In octavo.

In 1804, James Sowerby published the first number of another octavo work, entitled, *The British Miscellany, or colored figures of new, rare, or little known animal subjects, not before ascertained to be inhabitants of the British Isles*, &c. The few insects figured are highly interesting; but the work, from want of liberal support, has never been continued beyond 12 or 15 numbers.

The seventh volume of the Transactions of the Linnean Society of London appeared this year, in which is the following paper, "Account of the Tusseux and Arrindly Silkworms of Bengal, by Wm. Roxburgh, M.D." In the same year, *Dictionnaire des Sciences Naturelles*. Par plusieurs Professeurs du Muséum National d'Histoire Naturelle et des autres principales Ecoles de Paris (l'Histoire des Insectes, par le Professeur C. Duméril,) Paris. Octavo.

The *Annuales du Muséum National d'histoire naturelle a Paris*, appeared this year in quarto, volume first.

E. Donovan this year gave to the world another work on exotic insects, in quarto, entitled, *An Epitome of the Natural History of the Insects of New Holland, New Zealand, and New Guinea, Otahiti, and other Islands in the Great Indian, Southern and Pacific Oceans, including the figures and descriptions of one hundred and fifty-three species*, &c. This publication is extremely valuable, not only from the beauty and accuracy of the engravings and descriptions, but also from its rarity, few copies having been published.

Likewise, *Journal de la Société des Naturalistes de Goldfarb.*
Den, entitled *Insecta Svecica descripta* a Leonardo Gyllenhal, volume the first, which treats of the coleoptera; a second volume, on the same order, has lately reached this country. The descriptions of the species are far more elaborate than any we have yet seen, except Mr Kirby's *Monog. Ap. Aug.* and if continued, will be the best general work on the Swedish insects that has hitherto appeared.

The ninth volume of the Transactions of the Linnean Society of London appeared this year, in which we find, "The genus *Apion* of Herbst's Natur. System considered, its characters laid down, and many of the species described, by the Rev. W. Kirby."—Some observations on the insect which destroys the wheat, supposed to be the wire-worm, by Thomas Walford, Esq. with additional notes by T. Marsham, Esq."—*Descriptions of Notocela,* a new genus of coleopterous insects, from New Holland, by T. Marsham, Esq."

In 1809, the fourth volume, completing the *Genra Insectorum et Insectorum* of Latreille, was published.

In 1810, P. A. Latreille published an interesting work, in one volume, in the French language, entitled, *Considerations sur l'Ordre Naturel des Crustacées, des Arachnides et des Insectes.*

In 1811, the second part of the tenth volume of the Transactions of the Linnean Society of London was published, in which we find, "Description of several new species of *Apion,* by the Rev. W. Kirby."—Some account of an insect of the genus *Buprestis,* taken alive out of wood composing a desk which had been made more than twenty years; in a letter to Alex. M'Leay, Esq. by Thos. Marsham, Esq." And among the extracts from the minute book, we find notice of *Forficula gigantea* of Fabricius having been taken in Britain.

In 1813, the first part of the eleventh volume of the Transactions of the Linnean Society of London appeared, in which the following entomological papers are given: "An Essay on the British species of the genus *Melice,* with descriptions of two exotic species; by William Ellford Leach, Esq. F. L. S."—"Strepsiptera, a new order of insects proposed, and the characters of the order with those of its genera laid down; by the Rev. William Kirby, F. L. S."—"A Monograph of the British species of the genus *Cholera,*" by William Spence, Esq. F. L. S."

In 1814, commenced a new work, (which has since been continued in monthly numbers), entitled, *The Zoological Miscellany, or Descriptions of new, rare, or highly interesting Animals;* by William Ellford Leach, M. D. &c. *Illustrated with Coloured Figures, accurately drawn from Nature;* by R. P. Nodder, animal painter. This work contains descriptions and figures of several new and curious insects.

**List of Entomological Works not mentioned in the preceding pages.**

Entomology.

Subclass I. AMETABOLIA.
Insects undergoing no metamorphoses.

Order I. THYSANURA. Tail armed with setae.
Order II. ANOPLURA. Tail without setae.

Subclass II. METABOLIA.
Insects undergoing metamorphoses.

Century I. ELythiroptera. Insects with elytra.

Cohors. I. ODONTOSTOMA. Mouth with mandibles.
* Metamorphoses incomplete.

Order III. COLEOPTERA. Wings transversely folded; elytra crustaceous, covering the wings, with the suture straight.
** Metamorphosis nearly complete.

Order IV. STREPSIPTERA. Wings longitudinally folded; elytra coriaceous, not covering the wings.
*** Metamorphoses semi-complete.

Order V. DERMAPTERA. Wings longitudinally and transversely folded; elytra somewhat crustaceous, abbreviated, with the suture straight.

Order VI. ORTHOPTERA. Wings longitudinally folded; the internal margin of one elytron covering the same part of the other; elytra coriaceous.

Order VII. DICTOPTERA. Wings longitudinally folded twice or more; elytra coriaceous, narrow, one decussating the other obliquely.

Cohors. II. SIPHONOSTOMA. Mouth with an articulated rostrum.

Century VIII. HEMIPTERA. Elytra somewhat crustaceous, or coriaceous; towards the apex generally membranaceous, horizontal, one decussating the other obliquely. Metamorphoses half complete.

Order IX. OMOPTERA. Elytra entirely coriaceous, or membranaceous, and meeting obliquely, with a straight suture. Metamorphoses semi-complete, or incomplete.

Century II. MEDAMOPTERA. Insects without wings or elytra.

Order X. APERTA. Mouth with a tubular sucking rostrum. Metamorphoses incomplete.

Century III. GYMNOPTERA. Insects with wings, but no elytra.

Classification.

By this term, we mean the distribution of insects into subclasses, orders, tribes, families, genera, and species; and we shall take our outline from the system proposed by Dr. Leach, of which the following is a tabular view.

Subclass I. Glossostoma. Mouth with a spiral tongue.

Order XI. Lepidoptera. Wings four, membranaceous, with pterigostea, covered with meal-like scales.

Cohors. II. Gnathostoma. Mouth with maxillae and lips.

Order XII. Trichoptera. Wings four, membranaceous, with pterigostea, and hairy.

Cohors. III. Odontostoma. Mouth with mandibles, maxillae, and lips.

Order XIII. Neuroptera. Four highly reticulated wings, generally equal in size; anus of the female without a sting, or compound borer.

Order XIV. Hymenoptera. Four vespoid wings, hinder ones smallest; anus of the female with a sting, or with a compound borer or oviduct.

Cohors. IV. Siphonostoma. Mouth tubular, formed for sucking.

Order XV. Diptera. Wings, and halteres or balancers two.

Subclass I. Insecta AMETABOLIA.

Order I. Thyisanura.

Tail furnished with setae, or filaments. Mouth with Thyisanummandibles, palp, labrum, and labium.

The bodies of the animals which compose this order, are generally covered with scales or hair. Their motion is extremely rapid, or performed by leaping.

Tribe I. Lepismides.

Palpi very distinct and prominent, or exserted. Antennae composed of vast number of very short joints. Tail with three exserted setae.

Family I. Lepisma.

Body depressed, and moving with a running motion. Tail with three nearly equal filaments.

I. Lepisma.

Antennae inserted between the eyes. Maxillary palpi slender, composed of five joints, the last of which is elongate, and very slender. Labial palpi with their joints compressed, dilated, and rounded. Eyes small and remote.

ENTOMOLOGY.

77

Ametabolia.

This is the only species known. It is very common amongst books, clothes, &c. and wanders about during the night. It is supposed to have been originally introduced into Europe from America, where it is said to live amongst sugar.

FAMILY II. Forbicinida.

Body convex, with an arched back formed for springing. Tail with three setae, the middle one longest.

Genus II. Forbicina. Geoff.

lepisma. Linn. Oliv.

Maxilla. Latr.

Antennae inserted under the eyes, shorter than the body. Maxillary palpi thick, with six joints, the last conic. Labial palpi, with the apex membranaceous. Eyes large and contiguous.

Lepisma polyopa. Linn.

Lepisma saccharina. Vill. Ent. 4. tab. 11. fig. 1.

La Forbicina cylindrique. Geoff.

Inhabits all the temperate parts of Europe, and is found in woods, and under stones.

Lepisma. Fabr.

Antennae longer than the body, inserted under the eyes. Maxillary palpi six-jointed, the fifth joint inversely conic, the sixth conic. Labial palpi, with the last joint obliquely truncate, with the apex acute, and not membranaceous. Eyes large and contiguous.

Inhabits all the rocky shores of Britain. Dr Leach first observed this species on the Devonshire coast, and afterwards in Ireland, Scotland, and Wales. Can it be the Lepisma polyopa of Fabricius?

Tribe II. Podurellides.

Palpi not exerted, nor very conspicuous. Antennae composed of four joints, the last sometimes formed of several other minute articulations. Tail forked, and bent beneath the abdomen.

Antennæ with the last joint solid, not articulated. Abdomen elongate, linear.

Podura plumbea. Linn. Fabr. Lat.

Podura plumbea. De Geer.

La Podura grise commune. Geoff.

Inhabits Europe, under stones. A good figure may be found in Roemer's Genera Insectorum, tab. 29 fig. 2.

There are a vast number of species in this and the following genus, which are worthy of attention. Fabricius, who placed these two genera together without the slightest distinction, has described several species, to which we cannot refer, from not having studied his species, which we trust some future zoologist will be induced to examine.

La Podura brun enflammée. Geoff.

Podura brun, ronde. De Geer, Mem. sur les Ins. vii. 35. tab. 3. fig. 7, 8.

Podura atra. Linn. ? Fabr.

Synthrus fusiusculis. Linn.

Inhabits Europe, common on the ground, and in damp hedges.

Podura viridis. Linn. Fabr.

La Podura verte aux yeux noirs. Geoff.

Synthrus viridis. Linn.

Inhabits various trees in Europe.

ORDER II. ANOPLURA.

Tail without setae or filaments. Mouth in some furnished with two teeth, (or mandibles) and an opening beneath; in others with a tubulose, very short haustellum.

The animals of this order are parasitical, and were by Latreille placed in an order which he named Parasita. This name Dr Leach has changed for the sake of harmony, and also to render the name more easy of retention in the memory, the characters being drawn from the same parts.

Their motion is slow, and their nourishment is derived from the blood of mammalia, birds, and insects. It is almost an established fact, that every species of bird (and probably mammiferous animal) has its own peculiar parasite; and there is no instance of the same species of louse having been observed on two distinct species of birds, although some birds (as the raven, oyster-catcher, &c.) are infested with several species of parasites. The importance of clearly ascertaining the truth, is such to the entomologist, that Dr Leach has employed a considerable portion of time, for the purpose of investigating and of describing the species with accuracy, little more than a bare catalogue of names and habitats having been given in the works of Limmeus, Fabricius, and Gmelin. The result of his examinations he does not consider himself as able to communicate at present; but it is his intention, when the subject has arrived at maturity, to give a paper on this order to the Linnean Society of London.

Tribe I. Pedicularis.

Mouth consisting of a tubulose, very short haustellum.

Genus VI. Phthirius. Leach.

Anterior pair of feet simple, two hinder pair didactyle. Thorax extremely short, scarcely visible.

Pedicularis ingualis. Redi.

Pedicularis pubis. Linn. Fabr. Latr.

Le morpion. Geoff.

Inhabits the pubes and eyebrows of men and women, especially of those of easy virtue, being commonly known under the titles crabs, crab-lice, &c.

Feet all armed with a finger and thumb. Thorax composed of three distinct equal segments.

Pedicularis humanus. Fabr. Linn. Latr.

Inhabits the bodies and garments of men, and is known by the name of the body-lice. On the continent of Europe, especially in Spain and Portugal, it is very abundant. In Britain it is of very rare occurrence, and may have been introduced from the neighbouring countries.
ENTOMOLOGY.

Metabris.  
Sp. 2. Cervicalis. Body oval, lobed, cinereous, with a black interrupted band on either side.

Cervicalis.  
Le pou ordinaire. Geoff.  

Pediculus humanus var. Linn.  
Pediculus cervicis. Latr.

Inhabits the heads of man throughout Europe. In Britain it is extremely common, especially in the heads and upper part of the backs of children, whence they are extracted by means of a fine toothed comb, or are destroyed by rubbing calomel, mixed with a little fat, amongst the roots of the hair. This species has been by many authors confused with the preceding species.

Tribe II. Nymphides.

7. Nymus.  
Mouth with a cavity, and two teeth, or mandibles.  
Genus VII. Nymus. Hermann.

The character of this genus is given in that of the tribe. All the species inhabit birds. The term ricinus having been used in botany is rejected, and that of Dr Hermann's is adopted.

Cornicis.  
Sp. 1. Cornicis. Whitish; head heart-shaped; segments of the thorax on each side produced into a tooth; abdomen oval, transversely banded with brown.

Ricinus cornicis. Latr.

Inhabits the Cornus cornic of Linnaeus.

Subclass II. Insecta METABOLIA.

Order III. Coleoptera.  

Class Eleutherata, Fabr.

This order is divided into five great sections, from the general number of joints in the tarsi.

Section I. Pentamera.

The number of joints in the tarsi is generally five, but in some of the aquatic genera the number is less.

Tribe I. Cicindelides.  
Maxillary palpi four, the interior ones two-jointed. Labial two. Antenna filiformes. Maxille furnished at their extremities with a distinct articulated hook. Mandibles with many teeth. Feet formed for running; hinder ones with trochanters.

Mentum broadly notched; internal side of the anterior tibia never notched; antennae not moniliform.

Carabus. De Geer.

Cicindela. Thumberg, Clairville.

Thorax somewhat heart-shaped. Abdomen very large, pedunculated, nearly inversely heart-shaped. Elytra emarginating and shielding the whole of the abdomen connected at the suture.

Antennae inserted beyond the apex of the eyes, under a little process. Clypeus of the same size with the labrum. Labial and external maxillary palpi, with the last joint at the apex much compressed, and gradually a little broader. Scutellum scarcely visible.

Mantissa.  

Manticora maxillaria. Fabr.

Cicindela gigantea. Thun.

Inhabits the Cape of Good Hope, and is figured by Herbst's Archives, tab. 46. fig. 6.

Genus IX. Collyris. Latr.

Collyris. Fabr.

Cicindela. Oliv.

Thorax long, cylindric-conic, narrow, attenuated in front. Abdomen long and narrow. Elytra not embracing the abdomen.

* With wings.

Sp. 1. Longicollis. Cynaceus; apex of the elytra Longicollis, notched; thighs red.

Collyris longicollis. Fabr.

Cicindela longicollis. Oliv.

Inhabits Bengal.

** Without wings.

Sp. 2. Apter. Black; elytra connected with the Apter, middle part rough; thighs red.

Collyris aperta, Fabr.

Cicindela aperta, Oliv.

Collyris aperta, Latr.

Inhabits the East Indies.

Genus X. Megascaphala. Latr.

Megalochelys, Illiger.

* Elytra connected; no wings.

Cicindela megaloschele, Fabr. Oliv.

Megasphala Senegalensis. Latr.

Inhabits Senegal.

** Elytra not connected; wings.

Sp. 2. Carolina. Purple-green; antennae, mouth, a Carolina lunula at the apex of the elytra, and the feet ferruginoso-yellowish.

Cicindela Carolina, Linn. Fabr.

Inhabits Carolina, where it is very abundant.

Thorax short. Elytra flat, rounded. External maxillary palpi as long as the labial. Antennae inserted into the anterior margin of the eye. Clypeus shorter than the labrum.

Sp. 1. Sylvatica. Obscure ances above; each elysium with an external lunula at the base, with a mark at the apex, and an intermediate transverse, narrow, sinuated band of white; with many impressed punctures near the suture.

Cicindela sylvatica, Linn. Oliv. Latr.

Cicindela derforles. De Geer. Mem. 4. 114. tab. 4. fig. 7.

Inhabits Europe. Is found on Martlesome Heath, Suffolk, occasionally; near Christchurch, in Hampshire, it is very common.

Sp. 2. Hybrida. Coppery-green, or obscure copper Hybrida. black above, often with a purple tint; each elytron with an external lunule at the base, another at the apex, with an intermediate transverse sinuous-toothed band of white; suture cupreous.

Cicindela lacheté. De Geer, Mem. 4. 115. pl. 4. fig. 8.

Inhabits the sandy maritime plains of Europe; near
ENTOMOLOGY.

Inhabits pathways and the banks of ponds. Cicindela semipunctata of Linné, Elaphrus semipunctatus of Fabricius, &c. is the same species. There is a variety of Paykull which has been taken in Norfolk and on the shore near Porto-Bello, Scotland, having little of the venous lustre.

Cicindela. Linn. Marsh.

Inhabits pathways and the banks of ponds. Cicindela semipunctata of Linné, Elaphrus semipunctatus of Fabricius, &c. is the same species. There is a variety of Paykull which has been taken in Norfolk and on the shore near Porto-Bello, Scotland, having little of the venous lustre.

Cicindela riparia. Linn. Marsh.

Inhabit moist banks, and marshes every where.

Sp. 2. Uigginsus. Coppery-zenesce, with round ci-

catrices, more distinctly punctured, centres purple, mar-
gin green, elevated, with cuprous spots between.

Elaphrus uliginosus. Fabr. Latr.

Inhabits marshy and hizzy ground. It is esteemed a rare species. It occurs in Battersea fields, near Lon-
don, and in the banks of wet ditches on the borders of the Links near Edinburgh, in great numbers.

Inhabits Barbary and the south of France.

Genus XVI. Clivina. Latr.

Tenebrion. Linn.

Carabus. Marsham.

Antennae moniliform, second joint much longer than the third. Mandibles dentated on their internal edge. Lip short and broad, without auricles. Tibia, anterior ones palmated.

Sp. 1. Giggas. Black, shining. Thorax lunate, behind Gigas. on each side with one dent. Elytra smooth, shoulders one-dentate. Mandibles sulcate, with the internal process large, dentate, with the apex acute.

Inhabits Barbary and the south of France.

Genus XVI. Clivina. Latr.

Tenebrion. Linn.

Carabus. Marsham.

Antennae moniliform, second joint longer than the third. Mandibles without teeth on their internal edge. Lip elongate, with two auricles. Anterior tibia generally notched.

* Anterior tibia externally dentate.

Elytra with punctured striae.

Tenebrion fossor. Linn.

Scarites arenarius. Fabr.

Clivina arenaria. Latr.

Carabus distans. Marsham.

Inhabits Europe under stones, especially in moist situations, where the ground is sandy.

** Anterior tibia, with obsolete teeth.

Scarites gibbus. Fabr.
ENTOMOLOGY.

Inhabits France and England in moist or damp banks.

Genus XVII. Morion. Latreille.
Antenna moniliiform, second joint much shorter than the third.

Monilicornis. Sp. 1. Monilicornis. Plain, elongate, very black, shining; thorax on each side at the posterior angles impressed; elytra striated.
Inhabits the American islands.

Scarites. Rossi.
Antenna filiform. Mandibles pointed. External maxillary palpi very long and filiform; labial palpi much shorter and subulate.

Genus XIX. Stagyna. Latr.
Cucujus. Fabr.
Antenna somewhat setaceous. Mandibles pointed; the internal edge projecting. Labial and external maxillary palpi terminated by a nearly secundiform joint.

Sp. 1. Rufipes. Brunneous-black, punctate; thorax somewhat sulcate; antenna and feet red.
Cucujus Rufipes. Fabr.
Inhabits Barbary.

Harpalus. Latreille.
Antenna not moniliiform, with the third joint much elongate. External maxillary palpi with the last joint, save one, longer than the last.

Planus. Sp. 1. Planus. Oblong, black more shining beneath; elytra with fine punctured strie; trochanter of hinder thighs acute.
Carabus planus. Fabr.
Carabus spiniger. Paykull, Oliv.
Harpalus leucophthalmus. Latreille.
Sphodrus planus. Clairville.
Inhabits Europe. It is found in cellars and woods. The Linnean name is rejected as absurd, most of the Carabides having white eyes after death, but never whilst living.

Harpalus. Latr.
Carabus. Illig. Panz.
Antenna not moniliiform, with the third joint not longer than the following articulations. External maxillary palpi with the last joint somewhat cylindrioc longer than the one before it, a little attenuated at its base, and truncate at the apex.

Pumicatus. Sp. 1. Pumicatus. Oblong, blackish brown; antennae and feet refuscens; thorax with an impressed dorsal line, and a little groove on each side behind; elytra with punctured striae.
Carabus pumicatus. Illig. Panz.
Inhabits France, Germany, and England, under stones.

Antenna with the third joint a little longer than those which follow. External maxillary palpi with the two last joints equal in length, the last attenuated at the base and apex.

Ruficornis. Sp. 1. Ruficornis. Head and thorax black; elytra obscure blackish brown, downy, punctulate, striated; thorax without foveole behind; antennae and feet red.

Harpalus rubecornis. Latr.
Inhabits Europe, under stones; the most common species of the genus.

Genus XXII. Zarbus. Clairville.
Harpalus. Latr.
Carabus. Fabr.
Antennae not moniliiform. External maxillary palpi with the last joint shorter than the one before it.

1. Tardus. Black above, somewhat fuscus beneath; antennae, tibiae and tarsi brown; thorax without foveole, the hinder margin and abdomen widely punctured; elytra with punctured striae.
Harpalus tardus. Latr.
Carabus gibbus. Fabr.
Inhabits the plains of France and Italy.
Genus XXIV. Tachinus. Clairville, Latr.
Carabus. Linn. Marsh.
Antenna not moniliiform. Mandibles pointed. Exterior maxillary and labial palpi filiform, terminated by a sharp-pointed joint.

Carabus. Fabr.
Antenna not moniliiform. Mandibles very obtuse. Labial and external maxillary palpi terminated by a nearly secundiform joint.

Carabus cassidens. Fabr. Illig.
Inhabits Europe; but is very rare.

Carabus. Fabr.
Antenna not moniliiform. Mandibles very obtuse. Exterior maxillary palpi filiform; the labial palpi terminated by a thick short-obovoid joint.

Sp. 1. Bipustulatus. Black; base of antennae, feet, bipustula-thorax, and wing-cases, red, the latter with a sutural lunate mark of black.
Carabus bipustulatus. Fabr.
Badister bipustulatus. Latr.
Inhabits France, Germany, and Britain.

** Elytra truncate at their extremities. Head and corselet narrower than the abdomen.

Anthia decemguttata. Latr.
Inhabits the Cape of Good Hope, where it is common.

Genus XXVIII. Graphipterus. Latr.
Cicindela. De Geer.
Anthia. Fabr.

Sp. 1. Multiguttata. Black; front, sides of the thorax, and margins of the wing-cases and sixteen spots pass white tomentose; the marginal band of each elytron bidentate within.

23. Zara. }
ENTOMOLOGY

Carabus multiguttatus. Oliv.

Anthia variegata. Fabr.

tom. i. p. 186, tab. 6, fig. 1.

Inhabits Egypt.

Carabus. Linn. Marsh.

Head and antennae, with the exception of the tips of the third and fourth joints, obscure blackish.

Carabus crepitans. Linn. Marsh.

Inhabits Europe under stones. It is rare in England.

There is a small variety found in France and Germany, that has not hitherto occurred in Britain.

Genus XXX. Echimthus. Leach.

Lelia. Latr.

Brachinus. Clairv.

Thorax short, cordiform, broader than long. Head not narrow behind. Neck not apparent. External maxillary palpi distinctly truncate; labial palpi with the last joint thicker. Abdomen nearly perfectly quadrate. Tarsi with the fourth joint bifid.

Sp. 1. Crepitans. Red-rusty; thorax narrowly truncate cordiform; elytra black-blue-green; abdomen blackish; antennae, with the exception of the tips of the third and fourth joints, obscure blackish.

Carabus crepitans. Linn. Marsh.

Inhabits Europe under stones. It is rare in England.

Genus Echimthus. Leach.

Lelia. Latr.

Brachinus. Clairv.

Thorax short, cordiform, broader than long. Head not narrow behind. Neck not apparent. External maxillary palpi distinctly truncate; labial palpi with the last joint thicker. Abdomen nearly perfectly quadrate. Tarsi with the fourth joint bifid.

Sp. 1. Cyanoecephalus. Intense blue-green; first joint of the antennae, thorax, thighs, and tufta, red; elytra with punctured striae, the spaces between the striae punctulately; knees black.

p. 191, tab. 6, fig. 12.

Inhabits Europe under the bark of trees, and on hot dry banks.

Genus XXXI. Risophilus. Leach.

Lelia. Latr.

Thorax cordiform, a little longer than broad. Head a little narrowed behind. Neck not apparent. Palpi filiform, terminated with a thick ovoid truncate joint. Abdomen very much depressed. Tarsi with the fourth joint bifid.

Sp. 1. Atrocephilus. Body pale yellowish; head black; mouth and thorax reddish; elytra obsolescently striated.

Carabus atrocephalis. Linn. Fabr.

Lelia atrocephalis. Latr.

Inhabits Europe under the bark of trees. In Britain it very frequently occurs, on the sandy plains which are thrown up from the sea, amongst the roots of juniper and other plants which grow in those parts.

Genus XXXII. Lebia. Latr.

Carabus. Linn. Fabr.

Sp. 1. Quadriraculatus. Thorax ferrugineous; head rugulose, black, with the mouth reddish; elytra striated, black; with two pale yellow spots on each; feet pale yellow.

Carabus quadriraculatus. Linn. Fabr.

Lebia quadriraculata. Linn.

Inhabits Europe under the bark of trees.

Genus XXXIII. Cymindis. Latr.

Tarsus. Clairville.

Sp. 1. Humeralis. Black, punctate; antennae, mouth, thorax, lateral margins of the elytra, the shoulders, and feet, red; elytra striated.

Cymindis humeralis. Latr.

Inhabits France, Sweden, Germany, and England; but is extremely rare.

Genus XXXIV. Zuphium. Latr.

Sp. 1. Olens. Red, minutely punctate; head (mouth excepted) black; elytra brown, obsolescently striate, with common red spot at the base, and another at the apex.

Carabus olens. Rossi Faun. Ebrus. i. tab. 6, fig. 2.

Zuphium olens. Latr.

Inhabits Italy and the southern parts of France.

Genus XXXV. Galerita. Fabr. Latr.

Inhabits North America. Is very well figured by Drury, in his Illustrations of Insects, tom. i. pl. 42. fig. 2.

Cicindela. Oliv.

Thorax cylindrical. Head not narrowed or lengthened behind. Mandibles much elongated and very prominent. Exterior maxillary and labial palpi terminated by a large nearly obconic joint. (maxillary ones much lengthened.) Lip elongate linear, with two sutures.

Sp. 1. Emarginata. Blue, punctate, villose; mouth, emargination antennae, and feet, red; thorax with an impressed longitudinal line; elytra with punctured striae; apex of the first, and middle of the third joint of the antennae, brown.

tom. i. p. 197, tab. 7, fig. 3.

Cicindela emarginata. Oliv.

Carabus dentatus. Ross.

Carabus chrysostomos. Marsham.

Inhabits France, Germany, Italy, and England. In the former and latter of these countries it is extremely rare. It has been taken near Hastings in Suffolk; specimens from that neighbourhood are preserved in Dr Leach's cabinet.
ENTOMOLOGY.

Attelabus. Linn.
Carabus. Oliv.

Thorax cylindrical. Head not elongated or narrowly behind in any great degree. Mandibles not remarkably long or prominent. Palpi filiform.

Observation. The structure of the mouth and the general appearance of this genus is that of Lebia.

Melanura. Sp. 1. Melanura. Green-blue; first joints of the antennae, elytra (apex excepted), breast, and feet, pale-rusty-red; thorax distinctly punctured; elytra slightly and widely punctured, the punctures arranged into obscure striae; knees, tarsi, and antennae (base excepted), blackish.

Inhabits Europe. In Britain it occurs near Swansea, and near Norwich in considerable abundance.

Thorax nearly conic. Head much narrowed behind and lengthened. Palpi filiform, the labial ones with the last joint oval-rounded.

Observation. In the structure of the mouth, this genus makes a near approach to Lebia, from which it differs in having the last joint of the labial palp more elongate. Latreille makes two divisions, which we suppose should constitute genera.

* Fourth joint of the tarsi bifid.

Agra aenea. Thorax punctate; elytra bidentate.

Agra aenea. Fabr.

Inhabits South America.

39. AGRA.

Surinamesis. Sp. 2. Surinamesis. Brunneous; head and thorax black; antennae intersected with white and black; elytra striated, with their apex bidentate; feet red.

Agra surinamesensis. Latr.

Inhabits Surinam.

Pennsylvania. Sp. 3. Pennsylvanica. Black; elytra red, with punctured striae at the base; marginal spot, another on the suture, and the tip, black; feet red; knees black.

Inhabits Pennsylvania.

** Lip not prominent; mandibles small, their internal edge neither toothed or prominent.

35. PANACEUS.

Genus XXXIX. Panaeus. Latr.

Thorax orbicular. Head narrower than the abdomen, with very prominent globular eyes. Neck distinct. Abdomen large, nearly quadrate.

Panaeus crux-major. Latr.

Inhabits Europe.

c. Labial and external maxillary palp with the last joint cylindrical-oval. Antennae crooked. Mandibles short.

Genus XL. Loriceria. Latr.

Antennae incurved. The first joints differing in size and in proportion from the others. Mandibles with the back toothed and undidentate. Thorax nearly orbicular. Neck distinct.

* Sp. 1. Aenea. Elytra with punctured striae; the fourth stria from the suture with three foveae.

Inhabits France, Germany, and England.

B. Anterior tibiae not notched on their internal edge.

a. Lip very short, not projecting beyond the first joint of the palpi. External base of the maxillae not remarkably ciliated. Abdomen more or less thick.

Tenellus. Linn.

Mandibles narrow, very long, bidentate at their extremities. Elytra embracing the abdomen. Labial and external maxillary palp with the last joint much compressed, concave and secundiform, or rather spoon-shaped. Thorax somewhat cordate.

Cyclus rostratus. Fabr. Latr.

Tenellus rostratus. Linn.

Inhabits Europe. In England it is rather uncommon, but in Scotland it occurs very frequently under stones.

Genus XLII. Calosoma. Fabr. Latr.

Inhabits Europe.

Mandibles neither very narrow or long. Thorax nearly orbicular. Abdomen nearly quadrate. Labial and external maxillary palp with the last joint somewhat conic or triangular.

Sp. 1. Sycophanta. Violet-black; elytra gold or coppery green, with about sixteen punctured striae on each, the intervals absolutely intersected transversely, the fourth, eighth, and twelfth from the suture, with some impressed spots.

- Carabus Sycophanta. Linn.

Calosoma Sycophanta. Fabr. Latr.

Inhabits the European woods. There are but few instances of its having occurred in this country, six specimens only being known to us that have been clearly ascertained to be British. Two of these from Ireland are preserved in the collection of Mr Sowerby; one in another in the collection of W. J. Hooker, Esq. of Halesworth; another in the museum of S. Wilkin, Esq., which was taken in the county of Norfolk with the preceding specimen; a fifth occurred in Devon, near Kingsbridge, which is now, with another specimen, in the collection of Dr Leach.

Calosoma Inquisitor of Fabricius is sometimes taken near London, and it has been taken by Dr Leach near Tavistock in Devonshire; but it must be esteemed a rare British insect. It is said sometimes to occur in plenty near Windsor, on the white thorn hedges, feeding on the larvae of lepidopterous insects.

Inflata. Marsh.

Inhabits Europe.

Carabus purpurascens is said to have been taken in Britain; but we have not been enabled to identify it with certainty.

Sp. 2. Calcinus. Black; margins of thorax and Carabus; elytra violet; thorax broader than long, deeply emargi-
Entomology.

83

Metabolia.

**Metabolia.**

*83*<br>

minate behind; each elytron with about fourteen striae; the fourth, eighth, and twelfth from the suture interrupted; the intervals with a distinct somewhat rugose line; abdomen ovate.

Inhabits the south of France, Germany, and Britain. It is sometimes found quite black, at other times with a tinge of fine violet. It is very plentiful in Ireland, Scotland, and England, especially in the two former countries.

Sp. 3. *Intricatus.* Black violet above, black beneath; thorax narrow, with nearly equal diameters; elytra with irregular striae, the intervals punctate-rugose; each elytron with three elevated catenulated lines.

Carabus intricatus. Linn. Latr.

Carabus cyanus. Fabr. Panzer.

Inhabits Europe. Is common in Germany and Sweden, but is rare in France. There is but one instance of its having occurred in Britain: Dr Leach took a single specimen under a stone in a wood opposite the Virtuous-Lady-Mine, on the river Tavy, below Tavistock in Devonshire, in the last week in May. It is singular, that Mr. Marsham, (who has every opportunity of examining the Linnean cabinet,) should have confounded the former species with this, as it will in no way agree with the character.

Sp. 4. *Nemoralis.* Black; margin of the elytra and sides of the thorax violet; elytra obscure copper, rugose, with three longitudinal rows of excavated spots.

Carabus nemoralis. Illig. Latr.

Inhabits France and Germany.

Sp. 5. *Monilis.* Brass- or violet-black above, black beneath; each elytron with about fourteen elevated lines, two in the middle more distinct than the rest; the fourth, eighth, and twelfth from the suture catenulated; abdomen elongate-oval.

Carabus monilis. Fabr. Latr.

Carabus catenatus. Marsh.

Inhabits England, France, and Germany. It varies in sculpture, those lines on each side of the entire line being very frequently uninterrupted.

Sp. 6. *Morbillosus.* Brass or black copper above, black beneath; each elytron with three ribs, one at the suture; the interstices with a catenulated line, and on each side of it, with a less distinct smooth punctate-rugose line; abdomen elongate-oval.

Carabus morbillosus. Fabr. Latr.

Carabus granulatus. Marsh.

Antennae quite black; thorax often or generally cuneiform or coppery; intermediate tibia with a reddish-tomentose line. It varies in colour, being sometimes violet, with the sides green, or entirely black-brown.

Inhabits Europe, under stones.

Sp. 7. *Arvensis.* Coppery or black above; antennae altogether black; each elytron with fourteen elevated lines, three slightly notched transversely; the fourth, eighth, twelfth from the suture catenulated; abdomen oval.

Carabus arvensis. Fabr. Illig.

Inhabits Germany, Sweden, and England.

b. Lip projecting as far as the first joint of the palpi; exterior base of the maxillae distinctly dilated; abdomen generally very flat.

Genus XLIV. Nebria. Latr.

Lip nearly quadrato, not projecting as far as the labrum, nor tricuspidate at its extremity; labial palpi not twice as long as the head; mandibles but little dilated externally.

* Back very much depressed.

Inhabits the sandy maritime shores of France, Germany, and South Wales.

Sp. 2. *Brexicollis.* Black shining antenue; palpi, Brexicollis, tibiae, and tarsi, brown; elytra with punctured striae.

Carabus infusis. Rossi.

Carabus brexicollis. Latr.

Inhabits Europe; is found under stones and under the bark of trees.

Carabus Gylenhalli of Schönherr, which was discovered as a native of Britain by Dr Leach, at the base of Ben Lomond in Scotland. Has since been taken in some parts of France, by the late Richard Rawlins, Esq. one of the most promising entomologists of our day. *Nebria sabulosa* has likewise been taken near Hull in Yorkshire, by W. Spence, Esq.

** Back convex. Gen. Helobium, Leach’s MSS.

Sp. 3. *Multipuncata.* Black-brassy above, black beneath; middle of each elytron with impressed dilated spots, in a double longitudinal series; the intervals somewhat catenated.

Nebria multipunctata. Latr.

Helobium multipunctatum. Leach’s MSS.

Inhabits the northern parts of Europe. In England it occurs near London occasionally, especially in Battersea-fields. It should be placed, in a natural series, next to *Elaphurus*, to which genus it approaches in habit and economy.

Genus XLV. Pogonophorus. Latr.

Leistus. Froelich, Clairville.

Manticora. Jurine.

Lip elongate, even to the labrum, the extremity with three spines; labial palpi twice as long as the head; mandibles with their external base much dilated.

Carabus spinibarbis. Fabr. Panzer.

Inhabits England, France, and Germany.

II. Body short ovoid, nearly hemispherical; labial palpi inserted nearly on the superior side of the lip. (Obs. These insects live near the water, and prepare the way to the following tribe.) Anterior tibiae notched.

Genus XLVI. Omophoron. Latr.

Carabus. Oliv.

Lip very small; labial palpi inserted on the superior margin of the lip.

Sp. 1. *Limbutum.* Pale-ferruginous; vertex of the Limbutum, head a spot behind the thorax; a humeral spot on the elytra, and the suture with two bands of green.

Scolytus limbutum. Fabr.

Omophoron limbutum. Latr.

Carabus limbutus. Oliv.

Inhabits France and Germany, in moist situations.
ENTOMOLOGY.

Tribe III. Dytides.

This tribe is at once distinguished from the Carabici, by the superior length of the hinder legs, which are formed for swimming.

1. Labial and external maxillary palpi filiform.

A. All the tarsi with five joints, the last of which is longest.

Scutellum distinct; anterior tarsi of the male patelliform; elytra of the female sulcate; external maxillary palpi with the last two joints equal.

Marginalis. Sp. 1. Marginalis. Ovate, olive-black above; luteous red beneath the scutellum, of the same colour with the elytra; clypeus, whole margin of the thorax, and border of the elytra, red clay-colour; bifurcate of the sternum lacinolate.

Inhabits Europe.

Linnaeus considered the sexes of this insect as distinct species, under the names Dyticus semistriatus and marginalis.

Dyticus circumflexus of Fabricius, the flavesculentulus of Latreille, is very abundant near London. It is distinguished from marginalis by its more elongate shape, by the bifurcate processes of the sternum being spineshaped, and by the colour of the scutellum, which is invariably ferruginous.

Genus XLVIII. Cylometes. Clairville.

Dyticus. Latreille.

Scutellum distinct; anterior tarsi of the male dilated, but not patelliform; elytra of the female not sulcate; exterior maxillary palpi with the last joint longer than the one before it.

Rupustulatus. Sp. 1. Rupustulatus. Oval, depressed, black; finely striated above the elytra with impressed points, which are obsolete; antennae labrum, two frontal spots; anterior tibiae and tarsi obscure red; eyes gray.

Dyticus bipustulatus. Linn. Fabr.

Dyticus bipustulatus. Latr.

Dyticus carbonarius. Gyll.

Inhabits the European waters everywhere.

Genus XLI. Laccophilus. Leach.

Laccophilus Minutus. Leach.

Inhabits stagnant waters.

Dyticus. Latr.

Scutellum, none. Antenna, with a fifth or seventh joint dilated. Labial palpi, bifurcate.

Crassicornis. Sp. 1. Crassicornis. Oval, convex, brown; head and thorax ferruginous; elytra sprinkled with impressed dots; antennae of the male thick.

Dyticus crassicornis. Latr.

Inhabits Germany and France. Thorax in each sex, with margined sides, with an impressed longitudinal line.

B. The four anterior tarsi, with four joints; no scutellum.

Hyphydrus. Illig. Duméril.

Dyticus. Marsh.

Body oval; the breadth exceeding the height.

Sp. 1. Fuscus. Oval, plain, black, pubescent, finely punctulated; elytra fuscous; antennae, feet, shoulders and external margins of the elytra, rufous.

Dyticus fuscus. Illig. Latr.

Inhabits the waters of Europe.

Hydrachna. Fabr.

Dyticus. Linn. Marsh.

Body nearly globose; the height exceeding the breadth.

Sp. 1. Ferrugineus. Observe ferruginous, impunctate; the base of the elytra with an impression at the base of the suture.

Dyticus ovatus. Linn.

Hydrachna ribea. Fabr.

Hyphydrus ferrugineus. Latr.

Inhabits Europe.

Dyticus ovatus of Illiger, Hydrochna ovata of Fabricius, differs from the above species, in having a more shining colour, in having the elytra darker and distinctly and widely punctured. May not the above be but sexual distinctions? Such is the opinion of Dr Leach, who could never find the sexes of each kind.

C. All the tarsi five-jointed; the first joint largest; with a scutellum.

Genus LIII. Palobius. Schönher, Leach.

Hydrobia. Clairville.

Hyphydrus. Latreille.

Dyticus. Marsham.

Hydrachna. Fabricius.

Antennae with the first joint longer and thicker than the rest.

Sp. 1. Hermanni. Black; head, transverse band on Hermanni, the thorax; base and border of the elytra and feet ferruginous.

Hydrachna Hermanni. Fabricius.

Inhabits the marshes of France and England. The last segments of the abdomen, when rubbed against the elytra, produce a noise.

II. External maxillary and labial palpi subulate; hinder thighs covered at their base with a shield-shaped plate.

Genus LIV. Haliphus. Latreille.

Hoplitus. Clairville.

Cnestodous. Illiger.

Dyticus. Geoffroy, Marsham.

Scutellum, none; body oval, thick.

Sp. 1. Impressus. Yellowish or ferruginous; elytra impressed with some obsolete abbreviated punctured strie, and with blackish lines and spots.

Inhabits France, England and Germany.

Tribe IV. Gyrinides.

Internal maxillary palpi composed of one part. Antennae very short. Eyes divides so as to appear as four. Four hinder feet compressed, foliaceous, formed for swimming.

Sp. 1. Natator. Oval; elytra with punctured striae; the inflected margin testaceous.

Gyrinus Natator. Gyll.

Inhabits stagnant waters.
ENTOMOLOGY.

Mandibles with their extremities entire. Antennae filiform or setaceous, often pectinated or serrated. Body convex, not jumping.

I. Palpi filiform.

Antennae filiform, serrated in both sexes. Thorax with the hinder margin applied to the base of the elytra. Body cylindrical, linear.

Inhabits France and Germany. In England it is very rare, but was once observed in very great abundance, by Dr Latham, in Darentwood, Kent.

Antennae serrated and filiform. Thorax with the hinder margin lobed, and applied to the base of the elytra. Scutellum obsolete. Body short, ovate or triangular.

Inhabits the nut-tree and elm.

58. Aphanisticus. Latrille.

Antennae massive.

Aphanisticus fabri. Latr.

II. Palpi terminated by a thick joint.

Tarsi with entire joints.

Melas flavicornis. Latr.

Sp. 1. Flabellicornis. Obscure blackish; antennae, tibiae, and tarsi red-brown; head punctate; thorax rough, with elevated punctures, having an impressed dorsal line; elytra finely rugulose and striated.

Elater flavicornis. Linn.

Melas flavicornis. Latr.

Inhabits Germany and the south of France. In England it has been once taken, by Mr John Curtis of Norwich, a most industrious entomologist.

60. Cerophyllum. Latr.

Tarsi with the last joint bifid.

TRIBE VI. Elateridae.

Mandibles notched, or bifid at their extremities. Antennae filiform. Body leaping. Hinder thighs with a trochanter.

61. Elater. Linn.

Obs. This genus should be divided into several others, but the characters have not yet been developed. In Latreille's Genera Crustaceaet Insectorum, we find several sections, of which we shall give some account. The last joint of the tarsi is not notched. The maxillary palpi much exerted.

The last joint of the antennae with the apex so abruptly acuminate as to give the appearance of a twelfth joint.

Sp. 1. Ferrugineus. Antennae serrated; colour black. Thorax, with the exception of the hinder margin and elytra, red, finely punctated, pubescent; elytra with punctured striae.

Inhabits rotten trees, especially willows. In Britain it is very rare. It sometimes occurs in Kent, varies in size, and occasionally is found with the thorax entirely black. This last variety is in Dr Leach's collection.

1. Body not linear, but three times as long as broad; abdomen oblong-triangular.

A. Antennae (of the male at least) pectinated or serrated.

Sp. 2. Castaneus. Antennae of the male pectinated; Castaneus, colour black; head and thorax red-tomentose; elytra yellow punctate-striated; apex black.

Inhabits Europe.

B. Antennae simple; joints conic.

Sp. 3. Mureus. Mureus, with cincereous down; thorax bituberculate; antennae and tarsi red.

Inhabits Europe. Is common on thistles.

TRIBE VII. Telephorides.

Tarsi with the last joint but one bifid. Antennae filiform, composed of ten joints. Elytra soft, flexible. Thorax nearly quadrate, or semicircular.

Chrysomela. Linnæus.

Cistula. Olivier.

Chicoreis. Marsham.

Dasculus. Latreille.

Maxillary palpi filiform, with the last joint somewhat cylindric; labial palpi not bifurcate. Body ovate. Feet all simple.

Chrysomela cerina. Linnæus.

Atopa cerina. Paykull, Fabricius.

Dasculus cerina. Latr. Gen. Crust. et Ins. 1. 252. tab. 7. fig. 11.

Inhabits Europe.

Genus LXIII. Cyphon. Fabricius, Paykull, Gyllenhal.

Eloides. Latreille.

Maxillary palpi filiform, the last joint somewhat cylindric. Labial palpi bifurcate. Body sub-ovate or round-ovate. Feet with their tibie simple, and their thighs not thickened.

Sp. 1. Pallidus. Sub-ovate, pale-red, punctuated, Pallidus, pubescent, eyes, antennae, with the exception of their base, apex of the elytra, and abdomen, blackish; thorax somewhat semicircular, transverse, lobate behind.

Cyphon pallidus. Fabricius.

Inhabits Europe in moist places.

ENTOMOLOGY.

Metabolla. red-fuscous or blackish, pubescent; thorax short, transverse, anterior margin nearly strait; feet and base of the antennae reddish.

64. SCI- 

TES. 

Maxillary palpi filiform, the last joint somewhat cylindric; labial palpi, bifurcate. Body ovate, inclining to round, convex. Feet, with their tibiae, terminated with a strong spine. Hinder thighs thickened and formed for leaping.

Hemisphe- 

rica.

Eloides hemisphaerius. Latreille.

65. Cupes. 

Genus LXV. Cupes. Fabricius, Latreille.

Palpi equal, the last joint truncate; maxillary palpi with their joints thick. Antenna, cylindric, simple. Maxille, with a double process, the external linear, internal small. Mandible with its points notched.

Capitata. 

66. Drilus. 

Maxillary palpi with their apex acute; labial short, somewhat cylindric. Antenna with their internal edge pectinated. Maxille with one process. Mandibles notched at their points. Body soft, anteriorly arcuate, inflexed.

Flavescens. 

Inhabits Europe. Is found in Darent Wood, Kent, amongst grass, in tolerable abundance.

Cantharis. Linn.

Mandibles with their entire end pointed. Antenne compressed, more or less serrate, inserted near each other. Palpi of the maxillé, with the last joint somewhat triangular, having their points broader. Head, with the mouth produced into a kind of rostrum. Maxille with one process. Elytra nearly of equal breadth. Thorax somewhat quadrate, the anterior margin transverse, strait.

Minutus. 

Sp. 1. Minutus. Elytra with four elevated lines; thorax black, with the margins much elevated; last joint of the antennae reddish.

Lycus minutus. Gyllenhall.

. Mandibles with their apex pointed and entire. Antenne approximate, the joints cylindric-conic; the second and third smallest. Maxillary palpi with the last joint cylindric-ovate, apex truncate. Head exserted. Maxille with one process. Thorax nearly quadrate, a little narrower before, the hinder angles produced and sharp. Body hard.

Sp. 1. Suturalis, black; thorax with a double excavation of fossula behind elytra blood-red, with the surface black, deeply punctate-striate.

Inhabits Germany.

Mandibles pointed at their tips, sharp, and entire. Antenne approximate, the joints cylindric and compressed, the third of the same length as the following joints, the second small. Head concealed by the thorax. Mouth small. Maxille with a double process. Maxillary palpi with the last joint triangular-ovate, compressed, the apex acute. Eyes very large. Body soft, of the male, with elytra and wings; of the female, apterous. Thorax semicircular.

Sp. 1. Spendidula. Oblong-brown; margin of the thorax livid-yellow, anteriorly with a transparent spot on each side; abdomen with the margins of the segments, anus and feet yellowish; breast reddish.

Lampyris splendidula. Linn. Latr.

Inhabits Europe; has never been found in Britain.

Genus LXX. TELEPHORUS. Schaeff. De Geer, 70. TELE-

PHORUS. Olv. Lam. Latr.

Telephorus fusca. Latr.

Inhabits Europe in the spring and beginning of the summer.

Genus LXXI. MALTHINUS. Latreille.

Antenne distant, joints elongate, cylindric. Maxille bifid. Mandibles with their points entire, and very sharp. Body soft. Palpi with their last joint ovate, acute. Elytra shorter than the abdomen. Head atteneduated behind more or less.

Sp. 1. Rufocollis. Head not very much attenuated behind; thorax not broader than long, distinctly margined behind; body blackish; head black; the two first joints of the antennae and thorax red; elytra with some obsolete striae towards the suture, the apex and two pectoral spots yellow; base of the feet, anterior thighs, and tibiae, and knees of the middle feet, fuscous; middle of the anns reddish.

Malthius rufocollis. Latr.

Inhabits France.

Sp. 2. Marginatus. Head but little attenuated behind; thorax broader than long, margined all round; body blackish; base of the antennae, whole margin of the thorax, and two pectoral spots, red-yellow; elytra somewhat smooth, yellow at their points; base of the feet and knees pale; abdomen with the sides and margins of the segments red-yellowish.

Cantharis biguttata. Panzer.

Inhabits France and Germany.

Sp. 3. Flavus. Head much attenuated behind; thora-

x not broader than long, margined nearly all round, the middle longitudinally impressed; body yellowish;
antennae (base excepted) vertex, and dorsal mark of the thorax, blackish; elytra with punctured striae, yellow at their points.

_Thaliporus minimus._ Olivier.

_Malthinus flavus._ Latr.

Inhabits France and England, in the oak.

_Sp. 4._ Collaris. Head much attenuated behind; thorax not broader than long, distinctly margined behind, and with a short impression; body yellowish; antennae (base excepted), head middle of the thorax, blackish; elytra smooth, somewhat fuscos, base darker, apex yellow.

Inhabits France.

Tribe VIII. Melyridae.

Tarsi with the last joint but one not bifid. Mandibles toothed. Maxilla bifid. Antenna filiform, composed of ten joints. Elytra soft, flexible. Thorax quadrate, or semicircular.

**Genus LXXII. Melyris.** Fabr. Oliv. Lam.

Head ovate, much inflected under the thorax. Antenna with the second and third joints nearly cylindric, the former elongate; the fourth and following joints turbinated or conic. Tarsi with the outer nails beyond the middle beneath distinctly undentate. Body oval. Thorax somewhat trapeziform, plain, narrower before.

**Viridis.**

_Sp. 1._ Viridis. Green, with three elevated lines on each elytron.

Inhabits the Cape of Good Hope.

**Genus LXXIII. Zygia.** Fabr. Oliv.

Head ovate, much inflected under the thorax. Antenna with the second and third joints somewhat cylindric, more slender, the former elongate; the fourth and following joints dentate-serrated, compressed, somewhat transverse. Tarsi with the outer nails beneath the apex obsolescent undentate. Body oval. Thorax somewhat trapeziform, anteriorly narrower, the middle elevated.

**Oblonza.**

_Sp. 1._ Oblonza. Red; head and elytra blue or blue-green.

Inhabits Syria and the kingdom of Murcia in Spain.

**Genus LXXIV. Dasites.** Payk. Fabr. Latr.

_Melyris._ Oliv. Lam. Illeg.

Head somewhat transverse, retracted within the thorax even to the eyes. Tarsi with nails apparently bifid. Antenna with short turbinated joints, nearly as broad as long. Lip with the apex deeply notched, almost bifid. Body without papillae.

_Sp. 1._ Ater. Oblong, black, widely punctate, hairy, the hairs black and cinnereous. Head with a double impression in front, which is ovate and roughish.

_Dasites ater._ Latr. Fabr.

_Melyris ater._ Olivier.

Inhabits Europe, amongst grass.

_Cantharis._ Linn. Marsh.

_Thallophorus._ Schaeffer, De Geer.

Head somewhat transverse, retracted even to the eyes within the thorax. Tarsi with apparently bifid nails. Antenna with conic or cylindric-conic joints, longer than broad, in some few pectinated. Labium with apex entire, or scarcely notched. Body with two papillæ on each side, one under the anterior angle of the thorax, the other at the base of the abdomen.

_Sp. 1._ Aeneus. Brassy-green; head anteriorly red-yellowish; elytra blood-red, with the base and half the suture brassy-green.

_Cantharis aenea._ Linn. Marsham.

Inhabits Europe.

**Genus LXXVI. Hylecætus.** Latr.

_Cantharis._ Linn.

Antennae serrated, the fourth, fifth, and following joints nearly equal. Elytra covering the back of the abdomen. Thorax broader than long. Head vertical. Body linear cylindric.

_Sp. 1._ Dermestoides. Pale red; eyes and breast Dermestoides black; or black elytra brown-black or testaceus with a black apex; antennae, feet, and apex of the abdomen testaceus reddish.

_Hylecætus dermestoides._ Latr.

Inhabits Germany.

The sexes of this insect seem to have been considered as distinct species. See Latr. Gen. Crust. et Ins. 1. 266.

**Genus LXXVII. Lymexylon.** Fabr. Oliv.

_Payk. Latr._

_Cantharis._ Linn.

_Elaeroides._ Schaff.

Head vertical. Body linear cylindric. Thorax longer than broad, nearly cylindric. Elytra nearly covering the whole elytra. Antenne simple, somewhat fusiform, the middle joints rather longest.

_Sp. 1._ Navale. Head black; thorax entirely or partly Navale, elytra or their base testaceus; under part of the body and the feet yellowish.

_Cantharis navalis_ of Linnaeus, who (as we have already mentioned in our history of entomological writers) wrote a dissertation on this destructive insect. The male, Fabricius has considered as distinct, under the title of _Lymexylon flavipes._

Inhabits in the oak of Europe, which it destroys.

**Genus LXXVIII. Atractocerus.** Palissot-Beauvois, Latr.

**Genus LXXIX. Atractocerus.** Palissot-Beauvois, Latr.

_Necydalis._ Linn.

_Lymexylon._ Fabr.

_Sp. 1._ Necydaloides. Head and thorax fuscos, with Necydaloides a longitudinal yellowish line.

_Atractocerus necydaloides._ Palissot-Beauvois, Latr.

_Necydalis brevicornis._ Linn.

_Lymexylon abbreviatum._ Fabr.

Inhabits Guinea.

**Tribe IX. Billidae.**

Antennae thicker at their extremities, serrated in some, solid in others. Elytra covering the whole abdomen. Body cylindric. Thorax narrow behind.

**Family I. Billida.**

Tarsi, with the first joint very apparent, longer than the one before it.

**Genus LXXX. Enoplus._ Latreille.**

_Tillus._ Oliv. Panz. Fabr.

_Dermestes._ Rossi.

_Palii filiform._ Antenna, with the three last joints much dilated, serrated. Thorax nearly quadrato.

_Eentomology._ 87
ENTOMOLOGY.

Dermestes dentatus. Rossi.
Tillus serraticornis. Olivier.

Enoplium serraticorne. Latreille.
Inhabits Italy.

Enoplium Weberi. Latreille.

Chrysomela. Linneus.
Clerus. Fabricius. Olivier.
Maxillary palpi filiform. Labial palpi secundiform.
Antennae nearly completely serrated. Thorax cylindrical, or somewhat cordate.

* Thorax cylindrical.

Elongatus.
Chrysomela elongata. Linneus.
Inhabits rotten trees.
T. ambulans is a mere variety of this species.

** Thorax subcordate.

Unifasciatus.
Tillus unifasciatus. Latreille.
Inhabits France, Germany, and England.

Genus LXXXI. Thanasimus. Latreille.
Attilatus. Linneus.
Ceroides. Scheffer.
Maxillary palpi filiform. Labial palpi secundiform.
Antennae with their extremities thick, and not serrated. Thorax somewhat cordate.

Formicatus.
Ceroides formicatus. Fabricius, Olivier, Marsham.
Ceroides fasciatus. Fournier.
Inhabits Europe in trees.

Family II. Clerida.

Tarsi, with the first joint very short, the upper part concealed by the base of the second articulation.

Opilus.
Genus LXXXII. Opilus. Latreille.
Attilatus. Linneus.
Clerus. Geoffroy, de Geer, Olivier.
Notoxus. Fabricius.
Eupucus. Illiger.
Palpi secundiform. Antennae with the ninth and tenth joints obovate, the last oval, obliquely truncate. Eyes not notched. Thorax conico-cylindric, narrower behind.

Sp. 1. Molles. Fuscos, villous. Base and apex of the elytra, and a middle transverse band, with the under part of the thighs yellowish gray. Abdomen red.
Notoxus molles. Fabricius.
Eupucus molles. Illiger.
Attilatus molles. Linneus.
Opilus molles. Latreille.
Inhabits Europe, under the bark of trees, especially of willows, eating the larvae of other insects.

Silphi.
Clerus. Linneus.
Trichodes. Herbst, Fabricius.
Maxillary palpi terminated by an oblique joint. Labial palpi, with the last joint secundiform. Antennae, with the three last joints forming an oblong triangular mass, externally rounded, internally acuminate. Eyes metathoracic. Thorax cono-cylindric.

Trichodes apiaarius. Fabricius.
Clarian apiaarius. De Geer, Geoffroy.
Inhabits the nest of bees. Mr Marsham has introduced this into the British Fauna, apparently without the least authority.

Genus LXXXIV. Necrobia. Latreille, Olivier.

Dermestes. Linneus.
Clerus. Geoffroy, de Geer, Marsham.
Corynetes. Paykull, Fabricius.
Palpi terminated with an obconic joint. Antennae, with the three last joints forming an oblong triangular mass, obtuse both externally and internally.

Dermestes rufescollis. Linnaeus.
Corynetes rufescollis. Fabr.
Inhabits Europe.

Family I. Silphida.

Silphi. Linnaeus.
Dermestes. Geoffroy.
Antennae gradually thickening towards their extremities, or terminated by a solid or perforated club. Elytra covering the greater portion of the abdomen. Body oval, or parallelopedial.

Family II. Silphidae.

Antennae not much longer than the head, terminated abruptly in a perforated knob. Elytra truncated in a straight line, the external margin not crenated or keeled. Body long, quadrate.

Inhabits France and England.
Necrophorus vesparum is readily distinguished from this species, by not having the trochanters produced into a spine.

Genus LXXXVI. Silphia. Linnaeus.
Dermestes. Geoffroy.
Silphia, Nicrodes, Oiceoptoma, Thanatophilus. Leach.

Antennae a little longer than the thorax. Elytra with an external margin. Body more or less oval. Maxillary palpi terminated by a joint, thinner than the one before it.

* Body elongate, oval. Thorax orbicular. Apex of elytra obliquely truncate. Hinder thighs of the male thicker than the rest.

Genus Necrophorus. Wilkin's M.S. Leach.
Obl. Kirby, Spence, Leach, and Wilkin, about the same time, considered this section as constituting a peculiar genus. We have adopted that name proposed by Mr Wilkin, as preferable to any other proposed by the above gentlemen.

Sp. 1. Littoralis. Black. Antennae, with the three Littoralis, last joints ferruginous. Elytra with three elevated lines, the two external ones connected by a tubercle. Hind leg of the male arcate; thighs of the same sex toothed.
Silphi littoralis. Linnaeus.
ENTOMOLOGY.

Genera LXXXIX. Scaphismata. Leach.

Scaphismata. Fabricius, Latreille, Olivier.

Obs. The hinder margin of the thorax at the middle produced into an angle.

Scaphidium agari cyanum. Leach's MSS.
Inhabits the 

Catops. Fabricius, Paykull, Gyllenhall.
Pseudophagus. Illiger.

Morrella. Forster, Marsham.
Hedops. Panzer.

Cistella. Olivier, Fabricius.
Lupinus. Frölich.

Dermestes. Rölli.
Antennae straight, with a five-jointed club. Maxillary palpi with the last joint subulate, conic. Labial palpi with last joint obtuse.

Obs. This genus has afforded the subject of a learned and interesting monograph, by W. Spence, Esq. published by the Linnean Society in the eleventh volume of their Transactions, to which we refer the reader for descriptions of the species.

Sp. 1. Oblonga. Narrow, oblong. Thorax narrow, behind, the hinder angles obtuse, the middle slightly foveolated. Antennae somewhat filiform.

Catula angustata. Fabricius.
Cholera oblonga. Latreille, Spence.

Catops elongatus. Paykull, Gyllenhall.
Pseudophagus rugescens. Illiger.

Morrella pieza. Marsham.

Lepidus cisteloides. Frölich.

Inhabits moss, and under stones.

Genus XCI. Myleicus. Latreille.

Catops. Paykull.

Cholera. Spence.

Antennae incurved, shorter than the thorax, the basal joints distinctly thicker than the rest; club five-jointed, the joints transverse. Palpi of the maxilla, with the last joint subulate. Labial palpi, with the last joint obtuse.

Catops brevicornis. Paykull.

Cholera brunnea. Spence.

Inhabits France, Sweden, and England, in which latter country it has occurred but twice.

Ips. Olivier, Latreille.

Dermestes. Fabricius, Scopoli, Panzer.

Body depressed, back plain. Tarsi with elongate slender joints. Antennae with a compact three-jointed club.

punctate, pubescent. Thorax finely dentilicate, on each side distinctly unidentate, anterior angles dilated, rounded, ending behind in an obsolete tooth.

Ips cellaris. Olivier, Latreille.

88. Scaphidium.

Antennae, with an abrupt club composed of five somewhat hemispheric joints. Body acuminate at each extremity. Elytra truncated. Palpi filiform. Scutellum distinct.

Inhabits fungi and rotten wood, in Germany, France, and England.

† The genus Thaumastophiles of Leach, which contains Silpha sianata of Fabricius, differs from this division merely in having the apex of the elytra of the female deeply notched; we have therefore not adopted it.
90

ENTOMOLOGY.

Olivier.

Inhabits houses. It varies with black elytra, having

the shoulders ferruginous.

Ips. Olivier.

Body depressed; back plain. Antennæ with a three-

jointed, much perforated club. Tarsi with the three

first joints short.

Humerus.

Sp. 1. *Humeralis*. Elliptic, black, shining, punctate;

antennæ, head, thorax, humeral spot on the elytra and

feet red, approaching to blood-red.

*Eugis humeralis*. Paykull, Fabricius, Gyllenhall.

*IPS humeralis*. Herbst.

*Daunec humeralis*. Latreille.

Inhabits Europe, under the bark of trees and in Bo-

leti. *Nitidula raffinos* of Marsham is scarcely distinct.

Genus XCVI. *Calobicus*. Latreille.

*Nitidula*. Rossi.

Morænes. Fabricius, Paykull.

Body depressed; back plain. Antennæ with a two-

jointed club. Mouth covered as with a hood.

antennæ, margins of the head, thorax, and elytra, fus-

cous-ferruginous; elytra with punctured striæ.

*Nitidula hirta*. Rossi.

Colobicus marginatus. Latreille.

Inhabits the south of France, under the bark of trees.

Length two lines.

Genus XCV. *Thymalus*. Latreille.

*Pelits*. Kugellan, Illiger, Paykull, Fabricius.

Ostoma. Laicharting.

Body depressed; back plain. Tarsi with the third

joint neither bifi'd nor dilated. Palpi terminated by a

thick joint. Mandibles prominent. Antennæ with a

three-jointed club.

Ferrugineus.

Sp. 1. *Ferrugineus*. Fuscos-ferruginous, with a pa-

ler border; thorax with impressed punctures; elytra

with six elevated lines on each, three of which are punc-

tulated; the interstices with a double series of excava-

ted punctures.

*Pelits ferruginea*. Kugellan, Fabricius, Illiger.

*Thymalus ferrugineus*. Latreille.

Inhabits northern Europe, under the bark of trees.

Latr.

Mandibles prominent. Body short, depressed; back

plain. Thorax generally broad. Antennæ with the third

joint twice as long as the second; club abrupt and

orbicular, composed of three joints.

Dipatulata. Body elliptic, brown-blackish; thorax

emarginate; elytra with a red spot on each.

Inhabitss dead carcasses and Boleti.

Genus XCVII. *IPS*. Fabricius, Herbst, Gyllenhall.

*Nitidula*. Latreille.

Mandibles prominent, strong, and much bent at their

points. Body elongate-quadrate; back plain. Thorax

transverse-quadrate. Antennæ with the third joint

twice as long as the second; club abrupt and orbicular,

composed of three joints.

Sp. 1. *Ferruginea*. Red-ferruginous punctate; the

punctures of the elytra running together at the suture;

mandibles black at their points.

*IPS ferruginea*. Fabr. Paykull, Panz.

*Nitidula linearis*. Latreille.

Inhabits Europe.

Genus XCVIII. *Bitemus*. Latr.

*IPS*. Olivier.

Antennæ with the third joint not twice as long as the

following joint; club composed of three joints. Man-

dibles prominent. Body oval or oblong; back plain.

Thorax broad behind, with the angles pointed. Elytra

covering the abdomen.

Sp. 1. *Tomentus*. Antennæ shorter than the tho-

rax; thorax short, the posterior angles broadly depre-

ed, reflected; body oval, black, with a reddish-yellow

down; antennæ and feet yellow-red.

Tomentus ferrugineus. Latreille.

Inhabits Europe, on the flowers of the ranunculus,

rose, &c.

Genus XCV. *Cateretes*. Herbst, Illiger.

Brachypterus. Kugellan.

Dermestes. Linn. Fabr.

Strongylus. Herbst.

*Nitidula*. Olivier.

Antennæ with the third and following joint scarcely

different in length; club compressed, perforated, obconic,

composed of three joints. Thorax rounded, without

angles behind. Elytra very short. Body depressed

back plain. Mandibles prominent.

FAMILY III. Mieropeplida.

Labial palpi scarcely distinct. Antennæ placed in

an excavation of the thorax. Mandibles with their

apex arcuate and acute.

Genus C. Mieropeplus.

Antennæ with the club composed of but one joint.

Maxillary palpi with the last joint subulate.

Staphylinus poratus. Paykull.

Inhabitss sandy ground.

Tribe XI. Staphylinidae.*

Antennæ gradually thickening towards their extreme-

ties, or terminated by a perfoliated mass. Elytra co-

vering about half the abdomen, or less, but very rarely

more. Body long, and more or less narrow.

Division I.

Anterior margin of the head (bearing the mandibles)

immediately behind the eyes, terminated by a transverse

straight line, (or with a line slightly bent in the middle,) not

rounded or crooked at their sides. Antennæ inserted

below the middle part of the above-mentioned line.

Thorax long. Neck distinct. Body very long and

narrow. Elytra covering a very small portion of the

abdomen.

Genus Cl. Astaophæus. Gravenhorst, Latreille.

Staphylinus. Fabricius, Olivier, Rossi.

Palpi terminated with a joint nearly secundiform. An-

tennæ nearly filiform, distinctly longer than the head,

* Gravenhorst has written an admirable monograph on this tribe, entitled, Monographia Coleopterorum Microptera-orum. Kirby, the

illustrious author of Monographia Apum Anglie, is about to publish a paper on this interesting tribe of insects.
ENTOMOLOGY.

Metabolia.

ULMI.

Biguttatus.

Tibiae.

Subdivision.

Astreus ulmi. Gravenherst, Latreille.

Staphylinus ulmi. Rossi.

Staphylinus ulminateus. Fabricius.

Inhabits Italy and the south of France under the bark of the elm.

Oliv. Lam. Graven. 

Palpi filiform. Antennae towards their extremities distinctly thicker, moniliform, the last joint obliquely truncate or emarginate. Lip deeply emarginate.

Sp. 1. Erythrops terus. Black; the greater part of the antenna, elytra, and feet, red; hinder margins of the head and thorax, the breast and a double series of spots on each side of the abdomen, golden yellow tomentose.

Inhabits Europe in dung.

Sp. 2. Politus. Black; head and thorax brassy-black; head ovate, narrower than the thorax, impressed with some distant dots; thorax with six or eight impressed dots, placed in a double longitudinal series; elytra darker, nearly smooth.

Staphylinus politus. Gravenherst, Latreille. 

Inhabits dung.

GENUS CIII. Lathrobium. Gravenherst, Latreille.

Pederus. Gravenherst, Fabricius, Olivier.

Staphylinus. Linn. Geoffroy.

Palpi subulate, with the last joint acicular and minute. Antennae nearly filiform, joints nearly conic, those towards the extremities more rounded, and somewhat globose. Lip deeply notched, nearly bilobate.

Sp. 1. Elongatum. Pubescent, minutely but widely punctured, black, shining; with the mouth, antennae, and apex of the elytra and feet, red-brown; head ovate; antennae about the length of the thorax, with the outermost joints nearly globose; thorax elongate-quadrate, with obtuse angles, the breasts equal, the middle dorsal line smooth.

Lathrobium elongatum. Gravenherst, Latreille.

Staphylinus elongatus. Linnaeus.

Pederus elongatus. Fabricius.

Inhabits putrid vegetables, and under stones.

Sp. 2. Rufocorne. Black-fuscous, pubescent, widely but finely punctate; mouth, antennae and thorax, red; elytra and feet yellow-red; antennae moniliform; thorax quadrate; dorsal line smooth.

Pederus bicolor. Gravenherst, Olivier.

Lathrobium rufocorne. Latreille. 

Inhabits France under stones.

DIVISION II.

Anterior margin of the head circumscribed by a curved line, the antennae inserted on this side of the level of the line. Elytra covering half the abdomen or more. Thorax generally longer than broad, or with equal diameters.

Subdivision 1.

Maxillary palpi longer than the labial one, with their extremities thickest; the last joint obscure. Body li.

near. Head with a distinct neck. Thorax orbicular or cylindrical.

Staphylinus. Linnaeus; Geoffroy, De Geer.

Antennae inserted before the eyes, insensibly thickening towards their extremities; the third joint very long. Eyes moderately large.

Sp. 1. Riparius. Body red, shining; head, antennae (four basal joints excepted,) apex of the abdomen, and knees, black; elytra blue, with wide impressed dots.

Staphylinus riparius. Linnaeus.

Inhabits banks and beneath stones.

GENUS CV. Stenus. Latr. Cuv. Lam. Fabr. Payk. 103. STE-

Grav.

Staphylinus. Linn. Marsh.

Pederus. Olivier. 

Antennae inserted at the interior margin of the eyes, abruptly thicker at their extremities, the inferior joints cylindrical, the outer ones conic-globose. Eyes nearly globose, large.

Sp. 1. Biguttatus. Black, with grey down, minutely punctate, somewhat rugulose; vertex of the head with an elevated line; thorax behind with an impressed little line; each elytron with a reddish round spot.

Staphylinus guttatus. Linnaeus, Marsham.

Inhabits Europe in moist places near water, as on the banks of streams or ponds.

Subdivision 2.

Maxillary palpi not much longer than the labial, not thicker at their extremities; the last joint distinct.

a. Mandibles strong, with their internal edge with one or more teeth. Head free.

b. The second, third, and fourth joints of the tarsi very short; the last joint as long as the others united.

GENUS CVI. Oxyporus. Fabr. Oliv. Lam. Grav. 106. Oxy-

Latr.

Antennae scarcely longer than the head, terminated by a perforated mass. Maxillary palpi filiform; the labial ones terminated by a very large lunate joint. Thorax semicircular. Head broader than the thorax.

Sp. 1. Rufus. Red; suture and apex of the elytra, Rufus.

Staphylinus rufus. Linn.

Inhabits boleti and other fungi.

GENUS CVII. Oxytelus. Grav. Latreille.

Antennae somewhat broken, incurved, thicker externally, with the last joints foliate above; the extreme joint globose ovate; the basal joint very long conic. Palpi subulate. Anterior tibiae very spiny, with their extremities notched or narrowed externally, with their tarsi capable of being reflected from their sides.

widely impresso-punctate, front unequal, somewhat inclined to be rugulose, the anterior space between the eyes rather smooth; thorax impressed on each side; the middle with three grooves and four carinae; the two middle ones joining together; feet blackish; tibiae with very short little spines.

Oxytelus carinatus. Gravenherst, Latreille. 

Inhabits the dung of men and other mammalia.

GENUS CVIII. Omalium. Gravenherst, Latreille. 

Staphylinus. Geoffroy, Fabricius, Olivier. 108. OMA-

LIUM.
ENTOMOLOGY.

**Metabolla.** Palpi filiform. Antennae thicker towards their extremities, the last joints rounded, somewhat perfoliate. Thorax transverse quadrate, the anterior angles rounded.

**Rivalare.** Sp. 1. *Rivalare. Blackish, punctate; base of the antennae and feet pale brown; head with two impressions between the eyes; thorax margined, impressed at the hinder angles, back with two grooves; elytra twice as long as the thorax; obscure brown.

*Omalus* *vivalis.* Graven. Latr.

*Staphylinus* *vivalis.* Paykull.

Inhabit France and England.

b. Tarsi with elongate joints, the last joint shorter than the others united.

**Genus CIX. Anthophagus.** Graven.

*Staphylinus.* Fabr. Paykull, Olivier.

Antennae nearly filiform, the second and following joints obscure. Palpi filiform. Thorax elongate, somewhat coniform, narrow and truncate behind.

*Carabus* *dimidiatus.* Paykull.

*Carabus* *staphylinoides.* Marsham.

*Lettera punctulata.* Lateille, Gen. Crust et Ins. 1. p. 297, tab. 9, fig. 1.

Inhabit France and England; in the last country it must be considered as of very rare occurrence.

**Genus CX. Proteinus.** Lateille.

Antennae evidently thicker towards their extremities.

Palpi subulate. Thorax transverse.

Sp. 1. *Brachypterus.* Depressed, flat, black, shining, smooth, silky above; mandibles, basal joint of the antennae, and feet, brown red; head a little narrower than the thorax, triangular; thorax short, smoothly and finely punctate, sextonella very small; elytra elongate quadrate, externally marginated; the hinder and external margins rounded; abdomen with the last joints raised.

*Proteinus* *brachypterus.* Latr.

Inhabit France and England.

2. Mandibles without denticulations on their internal edge. Head inserted into the thorax more or less.

a. Antennae wide apart, inserted before the eyes the fifth and following joints, longer than broad. Tibiae spinescent.

**Genus CXII. Tachinus.** Graven. Latr.

*Oxyopes* *Fabricius.*

*Staphylinus.* Linne, Geoffroy, Olivier, Paykull.

Sp. 1. *Hysteria.* Black, shining, smooth; antennae fuscous; elytra and feet generally brown; external apex of the elytra paler.

*Staphylinus* *rufipes.* Paykull.

*Tachinus* *enepes.* Gray. Latr.

*Oxyopes* *rufipes.* Fabricius?

Inhabit the dung of oxen and horses.

**Genus CXI. Tachionus.** Grav. Latr.

**Staphylinus.** Linne, Geoffroy, Olivier, Paykull.

Palpi filiform.

**Genus CXSP.** Chrysomelidae.

Sp. 1. *Chrysolina.* Black, shining, smooth; thorax, elytra (base excepted), and feet, red yellow; thorax somewhat transverse; abdomen with the extremity Metabola truncate.

*Tachyporus* *chrysomelius.* Grav. Latr.

*Oxyopes* *chrysomelius.* Fabr.

*Staphylinus* *chrysomelius.* Linne, Marsh.

Inhabit flowers, the roots of grass, and moss.

b. Antennae more or less approximate, inserted at the anterior internal margin of the eye, fifth and following joints broader than long. Tibiae not spiny.

**Genus CXIII. Aleochara.** Graven. Latreille.

Marsh

Head with the hinder part received into the thorax.

Obs. This genus certainly should be divided into three or more genera.

1. Head about as broad as the thorax, somewhat triangular; neck distinct, but not very slender; thorax quadrate, with rounded angles in some; somewhat orbiculate, as broad as the elytra behind in others.

Sp. 1. *Canaulata.* Red fuscous, feet paler; head and the two last joints, save one of the abdomen, black; elytra together transverse quadrate; back of the thorax excised with an impressed longitudinal line in the middle.

*Alcochara* *canaulata.* Grav. Latr.

*Staphylinus* *canaulatus.* Fabr.

Inhabit sandy banks and under stones.

2. Head globose, behind removed from the thorax with a very distinct slender neck; thorax somewhat globose, or somewhat cordate, rounded behind, narrower than the elytra.

Sp. 1. *Impressa.* Reddish, head black, thorax with Impressa, three lines, and with two impressions behind; base of the elytra with two little impressed lines.

*Alcochara* *impressa.* Grav. Latr.

Inhabit Agarics and Boleti.

**Genus CXIV. Lomechusa.** Grav. Latr.

Head disengaged from the thorax behind, with an inconspicuous neck or none. Thorax transverse, the sides rounded. Antennae distinctly perfoliated.

Sp. 1. *Bipunctata.* Black, somewhat silky, thorax Bipunctata, convex; elytra conjoined transverse quadrate, with a blood red spot in each; feet, hinder margin of the posterior segments of the abdomen, and anus, red brown.

*Alcochara* *bipunctata.* Lateille.

Inhabit horse dung.

Obs. In a natural arrangement of the genera, Porphyris should probably be placed after Lomechusa, but in the present infant state of our knowledge, we must keep that genus in the section Dimera.

**Tribe XII. Scydmaenidae.**

Body oblong, rounded at each extremity. Palpi very long. Tarsi short. Elytra hard, covering the abdomen. Antennae gradually thicker towards their extremities.

**Genus CXV. Mestaugas.** Hoffmannsegg, Lateille, 113. Mestaugas.

**Pinus.** Fabricius, Olivier.

Antennae filiform, (or nearly so), composed of long joints, geniculat. Maxillary palpi with the last joints forming an oval mass.

Inhabit Portugal; was discovered by Count Hoffmansegg. In Dr. Lestel's possession there are two specimens which were said to have been taken in Britain.

**Genus CXVI. Scydmaenius.** Latreille.

116. Scydmaenius.

Anticus. Fabricius.

Antennae gradually thickening towards their extremities. Maxillary palpi terminated by an acicular obscure joint.

Herbsti. Fabr.

*Pselaphus hellwigii.* Herbst, Paykull, Illiger.

Anthis. Fabr.

Sp. 122. Last joint of the maxillary palpi conical, terminal, the joints at the apex of the antennae not abruptly larger than the preceding ones. Thorax somewhat elongate-quadrate, a little narrower behind. Body deep castaneous, pubescent.

*Scydmenus hellwigii.* Latr.

Inhabits the roots of trees, and under moss.

Godarti.

tab. 8. fig. 6.

Inhabits France.

THIRTEENTH. *Ptinides.*

Antennae much longer than the head, filiform, or terminated by three large joints, not united into a mass.

DIVISION I.

Antennae uniform, not terminated, with three joints larger than the rest.

*Bruchius.* Geoffroy.

*Fur.*

Sp. 1. *Fur.* Red-fuscous. Thorax with four tubercles transversely striated, the two middle ones highest, with tufts of hair, contracted and margined behind. Abdomen ovate, rounded at the base. Elytra villose, with two yellow-grey bands. The second joint of the antennae shorter than the third. Under part of the body with short grey-yellow hairs.

Inhabits houses, committing horrid devastations in museums.

*Ptilinus testaceus* of Marsham, is merely the male of this species.

*Germanus.*

Sp. 2. *Germanus.* Fuscous. Thorax with four tubercles transversely striated; with short, obscure-red hairs, hinder part contracted and margined. Abdomen quadrate ovate, base straight, transverse, (not narrower.) Elytra blackish, with two hands of a spot at the apices, whitish; the shoulders prominent. Antennae with the second joint of the same magnitude with the third. Under part of the body with grey hairs. Thighs with a naked or brown band.

*Ptilinus Germanus.* Fabr. Latr.

Inhabits houses, with the other.

*Genus CXVIII. Gibium.* Scopoli, Latr.

*Bruchius.* Geoff.

*Scotias.* Czepinski.

*Scotias.*

*Gibium Scotiats.* Latr.

Inhabits the museums of southern Europe.

*Anobium.* Illiger.

*Serrophorus.* Kugellian.

*Ptilinus.* Linn. Marsh.

Antennae inserted before the eyes, very much peci- nated in the males, serrated in the females.

Body long ovoid, nearly cylindric. Thorax somewhat globose.

Inhabits old trees and houses, perforating them to de- struction. *Ptilinus serraticornis,* Marsham, is the female of this insect.

*Genus CXX. Xyletinus.* Latr.

*Ptilinus.* Illiger.

Antennae inserted before the eyes, serrated in both sexes. Body short ovoid.

*Xyletinus levis.* Illiger.

Inhabits Europe.

DIVISION II.

Antennae terminated by three joints different from the rest in size.

*Bruchius.* Geoff.

Antennae eleven-jointed, with the three last joints abruptly thicker than the others; the ninth and tenth joints obconic; the tenth oval.

*Thorax short transverse.

*Anobium tessalatum.* Fabr. Latr.

*Ptilinus tessalatus.* Marsham.

Inhabits Europe.

Eyes black.

*Ptilinus molles.* Linn.

Inhabits Europe.

*Thorax not much broader than long.

*Anobium pertinax.* Fabr. Paykull.

Inhabits Europe.

Antennae nine-jointed; the three last joints very long.

The seventh and eighth triangular, and much dilated on their internal side.

*Dorcatoma.*

Inhabits Europe.
Dermestidae. 

Antennae slender, longer than the head, and terminated by a large ovoid mass.

**Family I. Dermestida.**

Sternum not produced to the mouth, or over it like a neckcloth. Tibiae spinose.

**Genus CXVIII. Dermestes.** Linn. Fabr. Latr.

123. Dermestes. 

Marsh. Herbst, Oliv. 

Antennae with an ovate club, the last joint short, not (or but little) longer than the preceding joint. Body narrow-oval. Thorax with the hinder margin straight, or obtusely lobed. Palpi very short; maxillary palpi shorter than the maxille, or scarcely as long. 

*Sp. 1. Dermestes. Black; base of the elytra with a cinereous-band, with black points.

Inhabits Europe.

Dermestes, 2. Vulpinus. 3. Murinus. 4. Tessellatus are the other indigenous species of this genus.

**Genus CXIV. Attagenus.** Latr.* Leach.

**Genus Eclata. Herbst.**

Antennae with an elongate-ovate club, the last joint longer than the preceding, (especially in the male,) triangular or conic. Body broad-oval. Thorax with the posterior margin narrowly and acutely lobed. Maxillary palpi exserted, longer than the maxille; the last joint elongate-cylindric, very long in some. 

*Sp. 1. Pilula. Black; middle of the antennae and of the tarsi obscure red; hinder margin of the thorax with three spots, and the elytra with a spot on each side of the suture yellow-white; antenna of the male with the last joint ensiform, very long.

Dermestes nigra. Herbst. (Variety of the male.) 

Inhabits skins in houses, and is found sometimes on flowers.

*Sp. 2. Trifasciatus. Black; hinder margin of the thorax, three bands on the elytra, and the breast grey-villosse.

Dermestes trifasciatus. Fabr. Latr.

Inhabits Europe; is found in the south of France, in Sweden, and in Scotland.

**Family II. Megatomida.**

Sternum produced over the mouth, like a neckcloth. Tibiae not or but slightly spinied.

**Genus CXV. Megatoma.**† Herbst, Latr.

125. Megatoma. 

Linn. De Geer, Fabr.

Body narrow-oval. Antennae with an oval or oblong club, with the internal edge simple.

Megatoma undulatum. Latr.

**Tribe XV. Byrrhides.**

Body ovoid. Feet entirely or semicontractile. Sternum anteriorly produced to the mouth in the form of a neckcloth. Antennae thicker towards their extremities.

**Division I.**

Antennae with five very distinct articulations.

**Subdivision 1.**

Antennae straight, not inserted in the cavity of the eyes. Feet perfectly contractile. Mandibles but little, or not at all, prominent.

Lybrinus. Linn. Marsham.

Dermestes. De Geer.

Antennae shorter than the thorax, with the club solid. Palpi filiform, short. Body orbiculate ovate. Scutellum very minute.

*Sp. 1. Scrobalus latius. Black; sides of the thorax, and Scrobula-three transverse bands on the elytra, grey; suture and rim, external margin of the elytra, and hinder margin of the thorax, red-lutescent.

Anthrenus Scrobalus. Fabr. Latr.

Byrrhus scrobalus. Linn. Marsh.

Inhabits plants in Europe.

**Genus CXVII. Thosus.** Latr.

Elater. Linn. Olivier, Geoffroy.

Antennae as long as the thorax, with the three last joints large, forming an ovale club. Palpi short, with the last joint securniform. Body elliptic, narrow, depressed.

Obs. This genus probably belongs to the tribe Elaterides, from which it differs but in the structure of its antenna.

Elater dermestoides. Linn. Oliv.

Dermestes adstructor. Paykull, Illiger, Fabr.

Thosus dermestoides. Latr.

Inhabits European plants; is rare in Britain.

Linn. Illeg. Gyll.

Cistela. Geoffroy, Marsham.

Dermestes. De Geer.

Antennae a little shorter than the thorax, with the four or five terminal joints gradually thicker, compressed. Palpi short, the last joint longest, thick, somewhat ovate. Body somewhat ovate, very convex above. Scutellum minute.

Cistella undula of Marsham is merely a variety of this species.

**Genus CXIX. Chelonarium.** Fabr. Latr.

Antennae seven-jointed, the two last somewhat larger. Palpi with the last joint securniform. Body ovate, more convex below.

Chelonarium atrum. Fabricius? 

Inhabits the island of St. Domingo.

**Subdivision 2.**

Antennae elbowed or geniculated, not inserted in the...
ENTOMOLOGY.

DIVISION II.

Tarsi with four distinct joints.

Antennae composed of eleven joints, the seven last forming a dentate or serrated mass.

Sp. 1. Marginalus. Blackish, villose; sides of the margin of the thorax and abdomen, with spots on the elytra, margins of the abdomen, and feet, pale luteous.

Inhabits marshy places, burrowing in the muddy banks of ponds.

Antenna nine-jointed, the three last joints forming a rounded nearly solid mass.

TRIBE XVI. HYDROPHILES.

Antennae terminated by a club. Maxillary palp very long. Chin or mentum large, clypeiform. Head with the front rounded, cowl-shaped. Feet formed for swimming. Tarsi with the first joint shorter than the second.

FAMILY I. HELOPHERIDA.

Mandibles without teeth at their extremities. Maxillary palp generally much shorter than the antennae. Body oblong. Thorax somewhat quadrate, or nearly semi-ornicate, or somewhat cordate-truncate. Tibiae slightly shiny. Tarsi filiform, not ciliated, with two strong, acute, entire nails.

Spycere entire. Palpi with the last joint oval, thick; maxillary palp much shorter than the antennae.

* Body elliptic, or somewhat ovate. Thorax broader than long.

Elophorus aquaticus. Fabr. Olivier, Latr.

Inhabits ditches and stagnant pools of water.

** Body nearly linear; thorax elongate-quadrate.

Inhabits stagnant waters in England, France and Germany.

GENUS CXXXVII. HYDRENIUS. Leach. 137. Hydrenius. Marsham.

Elophorus. Paykull.

Spycere entire. Palpi with the last joint slender, acuminate; maxillary ones shorter than the antennae.

Elophorus pygmaeus. Paykull.

Elophorus minutus. Fabr.

Hydrophilus impressus. Marsham.

Inhabits the waters of Europe.

Attelabus. Geoffroy.

Body somewhat quadrate. Thorax transverse. Scutellum small. Elytra shorter than the abdomen. Breast very large. Head intruded into a concavity in the anterior part of the thorax. Palpi filiform, short, unequal, the last joint somewhat cylindrical, obtuse.

* Body depressed, the breath exceeding the height.

Tibiae broad, the breadth exceeding the height.

a. Body not very much depressed.

Inhabits dung.

b. Body very much depressed.

Inhabits beneath the bark of trees.

** Body very thick and high. Tibiae narrow, elongate. Tarsi slender.

Inhabits the dung of oxen and horses.

Subdivision 3.

Antennae straight, not inserted in the cavity of the eye.

Feet semicontractile.

GENUS CXXXI. NOSODENDRON. Latreille.

Byrrhus. Olivier.

Antennae terminated abruptly by a three-jointed perfoliated club, composed of three joints.

Sphæridium fasciculare. Fabr.

Byrrhus fasciculare. Olivier.

Nosodendron fasciculare. Latr.

Inhabits France and Germany, under the bark of elms.

GENUS CXXXII. LIMNIUS. Müller, Gyllenhal, Me
gerlei.

Dytiscus. Panzer.

Chrysomela. Marsham.

Ehnius. Latr.

Antennae nearly filiform, the last joint largest, somewhat oval.

Limnius Velekmani. Müller.

Ehnius Velekmani. Latr.

Chrysomela bifrostoides. Marsh.

Subdivision 4.

Antennae inserted in the anterior canthus of the eye.

GENUS CXXXIII. PARNUS. Fabr. Illiger, Marsh.

Dermestes. Geoffroy.

Elater. Rossi.

Dryops. Olivier, Lamarck, Latr.

* This genus seems to constitute a peculiar family, and might be divided into some very natural genera.

† This singular genus has the lip and maxilla of Helophorus; the general habit of Byrrhus; and the tarsi of Heterocerus.
ENTOMOLOGY.

**Hydraena Marginipennis.** Latr.
Hydraena marginipennis. Marsh.
Elophorus marginipes. Paykull.
Inhabits Europe.

**Genus CXXXVIII. Hydraena.** Kugel, Leach.
Elophorus, Gyllenhall.
Hydraena, Marsh.
Pallpi with the last joint acuminate at each extremity; maxillary palpi longer than the antenna. Clypeus emarginate.

**Hydropilus.** Longpalpi.
Hydropilus longipalpis. Marsh.
Inhabits running water.

**Family II. Hydrophilida.**

**Genus CXXXIX. Stercheus.** Fabr. Latr. Schönh.
Hydrophilus. Iliger, Marsh.

Hydrophilus, Linn.

**Luridus.**
Sp. 1. Luridus.
Hydrophilus luridus. Latr. Fabr.
Dytiscus luridus. Linn.
Inhabits stagnant waters.

**Limnopus.**
Hydrophilus piceinus. Marsh.
Inhabits springs and ditches.

**Hydropilus.** Marsh.
Dytiscus, Linn.

**Caraboides.**
Inhabits stagnant waters.

**Genus CXLIII. Hydrous.** Leach, from the Linnean MSS.

**Piceus.**
Hydrophilus piceus. Fabricius, Marsham.
Inhabits Europe in ditches.

**Tribe XVII. Sphariididae.**
Antennae terminated by a club. Maxillary palpi very long. Mentum large, clypeiform. Head with the front rounded, cowl-shaped. Feet formed for walking. Tarsi with the basal joint as long or longer than the second joint.

**Genus CXLIV. Sphariidium.** Fabricius, Olivier, Lamareck.

Sp. 1. Spharaboides. Black, shining, smooth; scutellum long-triangle; feet very spiny; each elytron at the base with a blood-red spot, and a livid reddish spot at the apex.

**Sphariidium spharioides.** Fabricius.
Sphariidium spharioides. var. A. Latreille.
Dermestes spharioides. Marsham, Linn.
Inhabits dung.

**Tribe XVIII. Coprides.**
Antennae eight or nine jointed, terminated by an abrupt lamellated mass. Anterior tibia large and dentated. Mentum not very large. Mandibles membranaceous. Maxilla membranaceous, Clypeus semi-circular.

**Family I. Coprida.**
Labial palpi very hairy, the last joint smaller than the preceding. Scutellum none, or very obscure. Wing-cases taken together, not longer than broad. Posterior feet situated near the anus.

**Division I.**
The posterior, and sometimes the intermediate, tibiae elongate, slender, little or not at all dilated at their extremities, nearly cylindrical.

Coplris, Geoffroy.
Actinophorus. Sturm.
Antennae nine-jointed. Body depressed. Elytra taken together square; not abruptly or deeply sinuated behind the shoulder. Hinder feet not much longer than the body. Labial palpi, with the basal joint quadrate oval. Anterior tibia with four strong teeth externally.

Ateuchus sacer. Fabricius.
Spharioides sturmii. Linn. Olivier.
Inhabits the southern parts of Europe and Africa.

**Genus CXLV. Gymnopleurus.** Illiger.
Ateuchus. Latreille, Fabricius.
Antennae nine-jointed. Body depressed. Coleoptera quadrate; their external margin behind the shoulders abruptly and deeply sinuated. Hinder feet not much longer than the body. Labial palpi with their basal joint somewhat quadrate. Anterior tibiae with three strong teeth externally.

Ateuchus flagellatus. Fabricius, Latreille.
Gymnopleurus flagellatus. Illiger.
Inhabits southern Europe and Africa.

**Genus CXLVI. Sphariidium.** Latreille.
Ateuchus. Illiger, Fabricius.
Copris, Geoffroy.
Sphariidium. Linn. Olivier.
Antennae eight-jointed. Coleoptera forming a triangle. Feet elongate; hinder ones much longer than the body.

---

* Insects of this genus are sculptured on the Egyptian monuments of antiquity, several specimens of which may be seen in the gallery of the British Museum.
ENTOMOLOGY.

TRIBE XIX. SCARABÆIDES.

Antennæ terminated by a conic club, obliquely truncate, the ninth joint infundibuliform, including the tenth and eleventh joints. Head produced behind the eyes. Abdomen very short. Hinder feet inserted at the anus. Scutellum very small. Coleoptra united, forming a triangle with the apex rounded; their sides involute inclined.

Inhabits eastern and southern Europe.

GENUS CL. IV. TYPHÆUS. Leach's MSS. Typhlus. Fabricius, Gyllenhall, Marsham. Antennæ terminated by an oval lamellated club. Thorax shorter than the abdomen; one each side in front with a long process, which extends along the sides of the head. Hinder feet distant from the anus. Head not produced behind the eyes. Scutellum obvious.

Sp. 1. Vulgaris. Typhalus. Typhalus. Fabricius, Gyllenhall, Marsham. Inhabits dung of horses on heaths; is found in spring and autumn in great plenty in many parts of Britain. Sciarabæus pumilus of Marsham, is merely a stunted or accidental variety of this species.

TRIBE XX. GEOTRUPIDES.

SCARABÆIDES. Latreille.

FAMILY I. Geotrupida.

No scale between the posterior angles of the thorax and the exterior base of the elytra.

DIVISION I.

Thorax almost quadrate, more or less transverse. Mandibles entirely corneous.

Metabola. with clavate thighs. Body with the transverse and perpendicular diameters nearly equal.

DIVISION II.

The four hinder tibiae short, or but little lengthened; much dilated at their extremities.

Subdivision 1.

Labial palpi, with the last joint, very distinct. Thorax much shorter than the elytra; much broader than long. Anterior tibiae long, arcuate.

145. Con.

149. Oni.

Subdivision 2.

Labial palpi with the last joint not distinct. Thorax longer than the elytra. Tibiae all terminated by a tarsus.

152. Oni.

FAMILY II. Aphonida.

Labial palpi nearly smooth, filiform, the joints nearly equal, cylindrical. Feet all separated by equal distances; hinder ones distant from the anus. Scutellum distinct.

151. Aphon.

* Onitis subea, Latreille; and Onitis elinns, Fabricius; have a scutellum, and should constitute a peculiar genus.

† Aphonides may be divided, for the sake of convenience, from the clypeus; 1. Clypeus smooth; emarginate; 2. Clypeus smooth, entire; 3. Clypeus tuberculate.

VOL. IX. PART I.
ENTOMOLOGY.

Subdivision 1.

Labrum prominent even beyond the clypeus. Maxillo; interiorly armed with a horny hook, simple or bifid. Body nearly globular or ovoid. Elytra tumid, embracing the sides of the abdomen.

**Genus CLV.** 
*Reticulatum.* Fabr. Linn. Olivier.

Geotrupes. Fabr.

Antenne with a club long and plaitable. Body ovoid, depressed. Mandibles with their external edge without teeth or folds. Maxille coriaceous, undivided. Thorax with its sides dilated and rounded.

Sp. 1. **Reticulatum.**

Geotrupes rictulatum. Fabr.

Inhabits Europe in old wood.

**Genus CLXI.** 
*Phileurus.* Latr.

**Genus CLXII.** 
*Geotrupes.* Fabr.

Geotrupes. Fabr.

Antenne with the lamellae of the club long and plaitable. Body ovoid, depressed. Mandibles with their external edge without teeth or folds. Maxille coriaceous, dentated.

**Genus CLXII.** 
*Punctatus.* Fabr.

Geotrupes punctatus. Fabr.

Phileurus punctatus. Latr.

**Genus CLXII.** 
*Geotrupes.* Fabr.

Scarabaeus. Linn. Olivier.

Scarabaeus punctatus. Latr.

Inhabits southern Europe.

b. Labrum with the anterior edge apparent. Clypeus quadrate. Scutellum large. (Colours various and gay.)

* External edge of the mandibles prominent, depressed, with the sides cutting, crenulated, or sinuate. (Body short, ovoid, or somewhat orbicular: Scutellum generally large: Thorax short, broad: Sternum produced into a point anteriorly.)

**Genus CLXII.** 
*Hedon.* Fabr. Linn. Lat. Linn. Olivier.

Hedon. Linn. Lat. Linn. Olivier.

SCARABÆUS. Linn. De Geer, Olivier.

CETONIA. Fabr.

Melolontha. Fabr.

Body more or less ovoid. Elytra with their exterior side dilated and channelled. Antenne ten-jointed, with a small oval club composed of three lamellae. Feet slender. Tarsi with very small nails.

Sp. 1. **Reticulatum.**

*Reticulatum.* Fabr.

Hedon reticulatum. Linn. De Geer, Olivier.

Inhabits Madagascar.

**Genus CLXII.** 
*Rutela.* Linn. De Geer, Olivier.

Cetonia. Fabr.

Melolontha. Fabr.

Body more or less ovoid. Elytra with their exterior side dilated and channelled. Antenne with their club large and oblong, composed of three lamellae. Mandibles with their points having three little teeth. Feet strong. Tarsi with strong nails.

* Tarsi with undivided nails; the nails of unequal size.

Sp. 1. **Punctata.**

Melolontha punctata. Fabr.

Inhabits America.

* * Tarsi with one nail divided, and another bifid. (Scutellum very large.)

Sp. 3. **Chrysis.**

Cetonia chrysis. Fabr.

Rutela chrysis. Linn. De Geer, Olivier.

Inhabits America.

* * Mandibles not, or but little, prominent, without any crenatures or sinuosities remarkable in their outer edge. (Body ovoid-oblong: Scutellum small or moderately sized.)
ENTOMOLOGY.

99

Metabolia.

Genus CLXIII. Melolontha. Fabricius, Olivier, Lamark, Latreille.

Elytra with their external edge not sinuated, very slightly narrower at their base than at their points. Tibiae armed with very distinct hairs.

Vulgaris.

Sp. 1. Vulgaris. (Common cockchafer.)
Melolontha vulgaris. Latreille, Fabricius.
Scaraeaeus melolontha. Linn.

Solstitialis.

Sp. 2. Solstitialis. (Summer cockchafer.)
Melolontha solstitialis. Fabricius, Latreille.
Scaraeaeus solstitialis. Linn.

Vitis.

Sp. 3. Vitis.
Melolontha viti. Fabricius, Latreille.

Horticola.

Sp. 4. Horticola. (Fernweh.)
Melolontha horticola. Fabricius.

Agricola.

Sp. 5. Agricola.
Melolontha agricola. Fabricius.

Obs. The genus Melolontha should be divided into a vast number of genera, of which the species are the types of those inhabiting Great Britain.

Genus CLXIV. Hoplia. Illiger, Latreille.

Melolontha. Fabricius, Olivier.

Elytra with their external edge sinuated. Tibiae with very obscure spurs or hairs.

Pulverulenta.

Melolontha pulverulenta. Fabricius.

Inhabits France, England, and Germany.

Division II.

Thorax as long as broad, nearly orbicular, or almost ovoid and truncate at the two extremities. Mandibles partly membranaceous, sometimes entirely coriaceous. Maxilla terminated by a membranaceous, or coriaceous lobe.

Subdivision 1.

Genus CLXV. Glaphyrum. Latreille.

Scaraeaeus. Linn.

Antenne terminated by a rounded knob, the two last joints received by the ninth joint.

Maurus.

Saraeaeus maurus. Linn.

Melolontha cardui. Fabr.

Melolontha maurus. Oliv.

Glaphyrum maurus. Latr.

Inhabits Barbary.

Genus CLXVI. Amphicoa. Latr.

Scaraeaeus. De Geer, Pallas.

Antenne with an ovoid club, having all the lamelle disengaged.

Melis.

Melolontha melis. Fabr.

Amphicoa melis. Latr.

Inhabits Barbary.

Subdivision 2.

Labrum not prominent. Mandibles entirely or partly membranaceous.

Genus CLXVII. Anisonyx. Latr.

Scaraeaeus. Linn.

Antenne with the first joint not very large. Clypeus porrect, a little narrower in front. Palpi very slender, long, terminated by a cylindric joint. Tarsi with unequal nails. Hinder feet large.

Scaraeaeus longipes. Linn.

Melolontha crinita. Fabr.

Anisonyx crinitum. Latr.

Inhabits the Cape of Good Hope.

Cetonia. Olivier.

Antenne with the first joint very large. Clypeus quadrate. Palpi short, with their last joints oval. Tarsi with equal nails.

* Body almost entirely (above at least) smooth. Hinder feet, with the tibiae and tarsi, of almost equal lengths.

Trichius nobilis. Fabr. Latr.

Cetonia nobilis. Oliv.

** Body tomentose. Hinder feet, with the tarsi most distinctly longer than the tibiae.

Sp. 2. Fasciatus.

Trichius fasciatus. Latreille, Fabr.

Cetonia fasciata. Olivier.

Inhabits Europe on umbelliferous flowers.

Genus CLXIX. Cremastocheius. Knoch, Latreille.

Antenne with the first joint very large. Clypeus transverse, the anterior margin reflected, arcuate, entire. Palpi short, with the last joint very long; cylindric, the apex obtuse. Thorax with the anterior angles dilated, tubearuliform. Tarsi with equal nails.

Cremastocheius castaneus. Latreille, Knoch.

Inhabits America.

Family II. Cetonia:

A triangular scale interposed between the posterior angles of the thorax, and the exterior of the base of the elytra.

Genus CLXX. Goliathus.

Goliath. Latreille.

Maxilla coriaceous, or very hard. Mentum very large. Thorax orbicular. Elytra slightly or not at all situated at their external edge. Clypeus with two diverging lobes.

Cetonia polyphemus. Fabr.

Goliath polyphemus. Latr.

Maxilla almost membranaceous; or coriaceous. Mentum moderately sized. Thorax triangular, with the anterior point truncate. Elytra abruptly situated at their external side, towards the base.

Scaraeaeus auratus. Linn. Marsham.

Cetonia aurata. Fabr. Latr.

Inhabits the flowers of roses.

Tribe XXI. Lucanides.

Antenne with a pectinate club. Anterior tibia large and dentated. Palpi four. Labrum generally
**ENTOMOLOGY.**

**Family I. Lucanida.**
Antennae geniculated. Labrum not discoverable. *Erodius*.

**Genus CLXXII. Lamprima.** Latreille.
**Lethrus.** Fabricius.
**Lucanus.** Schrebers, Donovan.
Thorax and elytra margined. Antennae with the first joint straight. Mandibles very large. Sternum produced into a horn. Anterior tibiae with a few teeth (four or five): and a scale of a triangular slope at the apex attached to the heel.

**Sp. I. Ero-**
Golden green, smooth.
**Lethrus ansus.** Fabricius.
**Lucanus ansus.** Schrebers.
**Lamprima ansa.** Latreille.

**Genus CLXXIII. Aesalus.** Fabricius, Latreille.
**Lucanus.** Panzer.

**Sp. I. Scarcobrochides.** Aesalus scarabrochides. Latreille, Fabricius.
**Lucanus scarabrochides.** Panzer.

**Sp. I. Bifenestra.** Bifenestra.
**Chirocephus bifenestra.** Latreille, Lamarck.
Inhabits New Holland.

**Genus CLXXVIII. Erodus.** Fabricius, Olivier, 1789. Erodus.

**Tenebrio.** Linn.
**Erodus gibbus.** Fabricius, Latreille.
Inhabits southern Europe.

**Division II.**
Antennae not terminated by a club. Anterior tibiae simple.

**Subdivision 1.**
Body nearly orbicular.
**Genus CLXXIX. Zophosis.** Linn.

**Genus CLXXX. Pimelia.** Fabricius, Olivier, 1802. Pimelia.

**Tenebrio.** Linn. Geoffroy.
Thorax much narrower than the abdomen, transverse. Abdomen nearly orbicular.

**Pimelia bifuncata.** Fabricius.
Inhabits southern Europe.

**Genus CLXXXII. Moluris.** Latreille.

**Tenebrio.** De Geer.
**Pimelia.** Fabricius, Olivier.
Thorax narrower than the abdomen, almost orbicular. Abdomen oval. Antennae gradually enlarging externally, the last joint almost ovoid.

**Sp. 1. Striata.** Striata.
**Pimelia striata.** Fabricius.
**Moluris striata.** Latreille.

Inhabits Africa.

**Genus CLXXXII. Tentyria.** Latreille.

---

*In some families they exhibit the appearance of twelve true joints; many species have the semblance of a twelfth articulation.*
ENTOMOLOGY.

Metabolla.

ARIS. Fabricius.
Pimelia. Olivier.

Thorax almost orbicular, narrower than the abdomen. Abdomen oval. Antennae filiform, terminated by two or three nearly globose joints.

Interupta.

Sp. 1. Interupta.
Tentytia interrupla. Latreille.
Pimelia glutara. Olivier.

Inhabits the western parts of France.

Subdivision 3.

Body oblong. Thorax flat above, more or less truncate-cordate. Elytra plain, or but little convex. Antennae with the third joint very long.

183. Axs.

Tenebrios. Linn.
Pimelia. Olivier.

Elytra united. Thorax with equal diameters, truncate behind. Abdomen oval, the external basal angles rounded. Scutellum very small but distinct.

Reflata.

Pimelia reflata. Olivier.

Inhabits Africa and southern Europe.

184. Eu-
yychorala.

Pimelia. Olivier.

Thorax wider behind, transverse, emarginate before; lateral margins elevated. Abdomen triangular, the base truncate. Scutellum none. Elytra united.

Ciliata.

Eurychorea ciliata. Latreille, Fabricius, Herbst.
Pimelia ciliata. Herbst.

Subdivision 4.

Body oblong. Thorax flat above, more or less quadrate.

185. Asida.

Genus CLXXXV. Asida. Latreille.
Machla. Herbst.
Tenebrio. Geoffroy.
Opaturum. Fabr. Olivier.
Pimelia. Panzer.

Thorax with the sides arched, reflexed, anterior margin concave. Antennae thicker towards their extremities.

Gira.

Opaturum gira. Fabricius.
Machla rugosa. Herbst.
Pimelia variolosa. Panzer.
Asida gira. Latreille.

Inhabits France, Germany, and Italy.

186. Heg-

Blaps. Olivier.

Thorax quadrate, the sides straight, not reflexed. Antennae filiform.

Blaps elongatus. Olivier.
Tenebrio striata. Latreille.

Inhabits Tenerife.

Family II. Blapsida.

Mentum small, or moderately large, quadrate or orbicular.

Division I.

Palpi filiform.

Genus CLXXXVII. Tegelna. Latreille.
Stenosis. Herbst.
Aks. Fabricius.

Sp. 1. Filiformis.
Stenosis augustata. Herbst.
Rhinoceror brentoides. Rossi.
Aks filformis. Fabricius.
Tegelna filiformis. Latreille.

Inhabits Africa and the south of France.

Genus CLXXXVIII. Scaurus. Fabricius, Olivier, 188. Scaru-

Latreille.

Pimelia. Oliveri.

Thorax almost quadrate. Abdomen oval, with the base truncate. Antennae with the third joint slender, nearly cylindrical; the eighth, ninth, and tenth, nearly globose; the eleventh conic. Anterior feet thick. Scutellum very small.

Pimelia carinata. Rossi.
Scaurus striatus. Latreille, Fabricius, Olivier.

Inhabits the south of France.

Genus CLXXXIX. Sepidium. Fabricius, Olivier, 189. Sepi-

Latreille.

Thorax truncated before and behind, the sides prominent. Scutellum indistinct. Abdomen oval; the base and apex truncate. Antennae with the third joint long, the tenth obconic, and the eleventh short ovoid.

Body elongate ovate.

Inhabits Africa and southern Europe.

Division II.

Palpi terminated by a thick joint; the last joint of the maxillary ones securiform.

Genus CXC. Misolamrus. Latreille.

Pimelia. Herbst.

Body convex. Thorax almost globose. Antennae with the third and fourth joints of equal length. Scutellum very minute.

Pimelia gibulasa. Herbst.

Inhabits Portugal. Discovered by Count Hoffmansegg.

Marshall, Latreille.

Tenebrio. Linn, Geoffroy.

Back flat. Thorax almost quadrate. Antennae with the third joint much longer than the fourth. Elytra with their extremities pointed.

Blaps morissa. Fabricius, Marshall, Latreille.

Tenebrio morissa. Linn.

Inhabits cellars and churches.

Division II.

Wings occasionally wanting. Antennae partly or entirely moniliform; inserted under the margin of the head. Elytra sometimes united, (in all) embracing the abdomen. Mentum small, not broader than long.

Subdivision 1.

Antennae generally serrate or pectinated. Head not produced into a rostrum bearing antennae. Maxil-

larly palpi terminated by a large obconic joint. Tarsi
ENTOMOLOGY.

Tribe II. Tenebrionides.

Mandibles bident at their extremities. Head more or less triangular, without a contraction behind, at its junction with the thorax.

Family I. Tenebrionidae.

Tarsi with entire joints. Antennae moniliform, not perforated or serrated. Maxillae unguiculata.

Genus CXCVI. Pedemus. Latr.

Helops. Olivier.

Opomus. Illig.

Body oval. Maxillary palpi terminated by a thick joint. Antennae filiform; the last joints globose or tubular.

Pedemus fomoralis. Latr.

Female.—Tenebrio fomoralis. Linn.

Blaps laticollis. Herbst.

Inhabits Europe in sandy places.

Silpha. Linn.

Body oval; Maxillary palpi, with their last joint oblongate; antennae gradually thicker, towards their extremities; the last joints transverse, compressed.

Opomus subulatum. Fabr. Latr.

Silpha subulata. Linn.

Inhabits Europe in sandy places.

Thorax behind as broad as the elytra, or scarcely narrower. Body elongate. Antennae scarcely gradually thickening towards their extremities, the eighth, ninth, and tenth joints transverse; the last subglobose. Mentum somewhat quadrate. Maxillary palpi with their last joint thick.

Inhabits Europe.

Subfamily. Sp. 2. Moltiur. (Meal beetle.)

Tenebrio moltiur. Linn. Fabr. Latr.

Inhabits houses; the larva in meal and flour; it is called meal worm.

Tenebrio. Latr.

Atelabus. Linn.

Thorax behind narrower than the elytra. Body elongate. Antennae thicker towards their extremities. Mentum ovate-quadrate; the upper margin rounded. Maxillary palpi with their last joint thick.

Atelabus ceramobus. Linn.

Upsi ceramobus. Fabr. Payk.

Tenebrio ceramobus. Latr.

Inhabits Sweden, in the Boletus fomentarius.

Family 2. Diaperida. ♀

Tarsi with entire joints. Antennae not moniliform, their extremities perforated or serrated.

Division I.

Genus CXCVII. Toxicum. Latr.

Antennae terminated by an oval compressed club, composed of four joints.

Tab. 3. fig. 9.

Inhabits the East Indies.

Sacrothrium. Linn. Marsh.

Tenebrio. De Geer.

Orthocherus. Latr.

Antennae with the last six joints forming a thick, fusiform, downy mass.

Sacrothrium. Linn. Marsh.

Orthocherus hircicornis. Latr.

Inhabits sandy places. In Britain it is rare, or at least very local. It has been found in gravel pits near Norwich, by Mr Joseph Hooker; in a similar situation near Hampstead, by Mr Stephens; and in the sandy shores near Swansea, in South Wales, it is very abundant in the months of June and July.

Division II.

Body linear. Thorax longer than broad. Antennae not moniliform, gradually thickening from the third joint; the extremity more or less perforated. Maxillae simple, not unguiculata.

Genus CXCVII. Hypophlebus. Fabr. Latr.

Hypophlebus. Linn. Marsh.

Antennae from the fifth joint perforated. Labrum exserted, Mentum short, almost transverse-linear. Thorax elongate-quadrate, margined.

Hypophlebus bicolor. Fabr. Latr.

Bicolor.

Inhabits under the bark of the elm.

Division III.

Antennae not moniliform. Body oval, or nearly orbicular; a little longer than broad.

Subdivision 1.

Antennae not serrated at their extremities.

Genus CXCV. Phaleria. Latr.

Phaleria. Fabr.

Anterior tibiae elongate-quadrate. Tarsi short. Antennae gradually thickening towards their extremities, where they are perforated. Body oval.

Tenebrio cadaverina. Fabr.

Inhabits sandy places.

Inhabits sandy places.

Chrysomela. Linn. Marsh.

Tenebrio. De Geer.

Antennae gradually enlarging towards their extremi-
Metabolis. Ties, from the fourth joint perforated. Body nearly hemispheric, very convex above.

Boletii.

Subdivision 2.

Antennae terminated by joints resembling in their form the teeth of a saw.

Genus CCVII. Eustrophus. Latr. Maxillary palpi with the last joint large obtriginate. Antennae with the last four joints dentiform. Mentum very large. Body elliptic or oblong. Thorax quadrato, or trapeziform.

Division IV.

Antennae nearly or quite filiform, with their extremities simple.

Subdivision 1.

Mandibles with their extremities bifid.

Obs. This genus is artificial; it comprehends the genera Helops, Platynotus, and part of Metandrya of Fabr. and part of the genus Serropalpus of Illiger, and the rejected genus Helaena of Latreille.

Subdivision 2.

Mandibles with their points cinctas. Tarsi with denticulated nails.
ENTOMOLOGY.

Four anterior tarsi with the last joint but one bilobate. Maxillary palpi with the last joint large, secerniform, or oblongate.

Division I.

Hinder tarsi with entire joints.

Body elliptic.

Metallina.

Caraboids.

Inhabits northern Europe.

Table III. Pyrochroides.

Head cordiform, abruptly stragulated at its junction with the thorax. Tarsi with their penultimate joints all bilobate. Body elongate, depressed, or convex and cylindrical. Thorax almost cordate.

Division I.

Antenne pectinated, serrated, or branched.

Cothaeus. Linn. Antenne pectinated or serrated. Thorax orbicular. The prevailing colour in this genus is red and black.

Division II.

Antennae simple.

Inhabits Europe.

* Hypulus quercus of Paykull is possibly referable to this genus.
ENTOMOLOGY.

Genus CCXXXII. ANIICUS. Payk. Fabr. Leach.
Genus CCXXXVI. ANIICUS. Payk. Fabr. Leach.
Genus CCXXXVIII. MELOE. Linn.
Genus CCXXXIX. TETRAONYX. Latr.
Genus CCXXXI. CISSITES. Latr. (rejected by this author). Leach.
Genus CCXXXII. OENAS. Latr.
Genus CCXXXIII. LYTTA. Fabr.
Genus CCXXXIV. LYTTA. Fabr.

Subdivision 2.

Head not produced into a rostrum, bearing antennae. Antennae simple. Tarsi with bifid nails.

Tribe V. CANTHRIDAE.

Head large, cordiform. Neck distinct. Mandibles not notched at their points. Thorax almost square, or cordiform. Elytra flexible. Tarsi generally with entire joints.

Family I. CEROCOMATIDAE.

Antennae clavate, or gradually thickening towards their extremity.

Family II. MELOIDA.

Antennae of equal thickness, tapering towards their points, or subclavate, as long or longer than the thorax, composed of globular or obconic joints.

Division I.

Penultimate joint of all the tarsi bifid.

Division II.

Tarsi with all their joints entire.

Subdivision 1.

Elytra covering the whole abdomen; their suture straight. Wings in all.

Subdivision 2.

Elytra covering only part of the abdomen; short, oval, diverging at the suture. Wings none.

In the 11th volume of the Transactions of the Linnean Society of London, two papers by Dr Leach, on the species of this genus, may be found, in which the species are arranged, from the structure of their antennae, into the following Sections.

Antennae filiform.
A. Longer than the thorax and head.
B. Shorter than the thorax and head.
1. The terminal joint emarginate.
2. The terminal joint entire.

Antennae thicker externally.
A. Thorax elongate.
B. Thorax transverse.

Antennae thicker, and curved in the middle.

FAMILY III. Cantharida.
Antennae composed of cylindrical or obconic joints, longer than the thorax.

Meloe. Linn.

Elytra soft, elongate, linear, with the sides somewhat inflected, the back convex, rounded. Maxillae with two membranous laciniæ, the external one acute within, subuncinate. Antennæ with the first joint larger than the others; the second very short; transverse; the rest obconic; the last ovate.

Veisatoria.

Meloe excavatorius. Linn.

Inhabits Europe; is found on the ash, but is rare in England; it is the common blister-fly of our shops.

GENUS CCXXV. ZONITIS. Fabr. Latr.

Apache. Olivi.

Elytra elongate, linear, soft, covering the whole of the abdomen, the sides a little inflected. Maxillæ not produced. Antennæ with the first joint of the same length with the third; the second a little shorter, obconic; the third and following cylindrical; the last fusiform, abruptly terminated by a short point.

Pseudos.

Zonitis pseustata. Fabr. Latr.

Inhabits southern Europe.

Nemognathus.

GENUS CCXXXVI. NEMOGNATHUS. Illiger. Latr.

Zonitis. Fabr.

Elytra elongate, linear. Maxillæ very much produced, filiform, and curved.

Viitata.

Zonitis viitata. Fabr.

Nemognathus viitata. Latr. Illiger.

GENUS CCXXXVII. APALUS. Linn. Latr. Fabr.

Elytra abruptly attenuated towards their extremity.

Antennæ with the two first joints shorter than the third.

Apalis apalis. Latr. Consid.

Inhabits southern France.

Subdivision 8.

Head produced into a rostrum bearing antennæ.

TRIBE VI. Oenederides.

Antennæ filiform or setaceous. Rostrum not very flat, and dilated at its extremity.

GENUS CCXXXVIII. Oenedera. Latr. Olivi.

Necydalis. Linn. Fabr.

Antennæ inserted at the anterior internal margin of the eyes. Rostrum not elongate. Eyes prominent.

Elytra subulate. Palpi with the last joint broader than the penultimate joint.

Necydalis coreila. Linneus, Fabricius.

Oenedera coreila. Latreille, Olivier.

Inhabits Europe.

GENUS CCXXXIX. STENOSTOMA. Latreille.

Leptura. Fabricius.

Antennæ inserted on the rostrum beyond the eyes.

Rostrum elongate, acute. Eyes not prominent. Elytra long, flexible, not subulate. Palpi with the last joint cylindric.

Sp. 1. Rostrata.

Leptura rostrata. Fabricius.

GENUS CCXL. MYSTERUS. Clairville, Olivier.

Mysterus. Fabr. Latr.

Mylabris. Scheffer.

Antennæ inserted before the eyes on the rostrum.

Rostrum elongate, narrow. Eyes globose, prominent.

Elytra hard. Palpi with the last joint compressed.

Rhinomacer curculionides. Fabricius, Latreille.

Mysterus griseus. Clairville.

Inhabits Europe; and has been taken in South Devon by Mr J. Cranch of Kingsbridge.

TRIBE VII. SALPINIOIDES.

Antennæ thicker at their extremities. Rostrum very flat, and dilated at its extremity.

GENUS CCXLI. SALPINUS. Illiger.

Curculio. Linn. De Geer, Marsh.

Anthribus. Fabricius, Paykull, Panzer, Clairville.

Rhinosimus. Latreille.

Antennæ inserted before the eyes. Elytra rigid.

Anthribus roboris. Paykull, Fabricius, Clairville.

Rhinosimus roboris. Latreille.

Curculio rusticollis. Linneus.

Inhabits Europe, beneath the bark of trees.

SECTION III. TETRAMERA.

Tarsi with four joints.

Division I.

Rynchothorae. Latreille.

Head anteriorly rostrated; the mouth at the apex of the rostrum.

TRIBE I. Brachides.

Palpi obvious, filiform, not very minute. Rostrum broad. Labrum exerted. Antennæ eleven-jointed; subclavate, with the club formed of distinct joints, in some; filiform, or gradually thicker towards their points, in others; serrated, or pectinated.

GENUS CCXLII. PLATYRHYNCHUS. Clairville.

Anthribus. Fabricius, Geoffroy, Paykull, Latr.

Macrocephalus. Olivier.

238. Oénedéra

239. Sténostostoa

240. Mysterus

241. Salpinus

242. Platyrrhynclus

Inhabits woods in Europe.

Macrocephalus. Olivier.

Antennae clavate, the club ovate, abrupt, increased. Eyes not emarginate. Elytra covering the anus above. Body short, oval, thick. Thorax transverse, broader behind, lobated. Rostrum short.

Inhabits pine trees.

Genus CCXLIV. *Rhinomacer*. Olivier, Fabricius. 

Anthribus. Paykull, Latreille. 

Antennae clavate, Eyes not emarginate. Elytra covering the anus above. Abdomen elongate, narrow. Thorax roundish, nearly equally broad. Rostrum at the base much narrower than the head, the longitudinal diameter many times exceeding the breadth. Tarsi, with the second joint not including the elb.

Mylabris. Geoffroy.

Antennae nearly filiform. Eyes emarginate, for the insertion of the antennae. Body short, oval, thick. Elytra not covering the anus above.

Inhabits southern Europe and northern America.

Head behind simply elongate, produced with no neck. Tibiae with their points furnished with a double hook. Body ovate. Abdomen quadrate, rounded behind. Labium corneous, quadrate, the middle of the upper margin emarginate, obtusely unidentate.

*Attelabus coryli*. Linneus, Latreille, Olivier. 

Inhabits the nut tree and willow.

Genus CCXLIX. *Apothecis*. Olivier, Latreille.

Inhabits London and the adjoining districts.

Rycchites. Linneus, De Geer, Marsham. 

Rhinomacer. Geoffroy, Clairville. 

*Attelabus*. Fabricius, Olivier. 

Head elongate behind the eyes, with no neck. Clypeus dentate. Tibiae with very short heels. Abdomen quadrate, rounded behind. Body ovate, narrowly produced before. Thorax conically-cylindric, broader behind, (often with a spine on each side in the male). Labium membranaceous, small, the apex rounded, villose, entire.

Sp. 1. *Baccha*. 

*Curculio bacchus*. Linneus, Marsham. 

*Rynochites bacchus*. Herbst, Latreille. 

*Attelabus bacchus*. Fabricius. 

Inhabits Europe, frequenting the nut and vine.

*Curculio*. Linneus, Marsham. 

Rhinomacer. Geoffroy, Clairville. 

*Attelabus*. Fabricius, Olivier. 

Obs. The Rev. William Kirby has given an admirable paper to the Linnean Society of London on the species of this genus, which is published in the ninth volume of their Transactions. He has added a supplement, which is published in the tenth volume.

Genus CCLII. *Rhamphus*. Clairville. 

Tarsi with the last joint but one bifid, cordiform. Head globose. Eyes approximate. Hinder feet formed for leaping. Tibiae with obsolete heels. Body short, oval.
ENTOMOLOGY.

106

Membino -

Sp. 1. Flavicornis.
Hampus flavicornis. Latreille, Clairville.
Inhabits the tree and aspen.

243. BRACHYCHERUS. Olivier, Herbst.

Cucullus. Linneaus, De Geer.
Tarsi short, with entire joints. Lip crustaceous, sub-circular, the apex truncate, retuse, entire. Body ovate, thick, gibbous. Eyes lateral. Tibia with their two points produced, the internal spine bifid. Thorax transverse. Abdomen large, subglobose, ovate, or oval.

Aligiris.

Brachycherus aligerus. Fabr. Latr.
Inhabits Africa.

DIVISION II.

(Fracticornes, ; geniculated horns.)

Antennae geniculated, the basal joint very much elongated, generally received in a lateral oblique groove, (at the base at least,) or the sides of the rostrum.

254. CURCULIO. Genus CCLIV. Cucullus. Linneaus, Fabricius, Clairville, Olivier.

Brachycherus. Latreille.

Imperialia.

Sp. 1. Imperialis, (diamond beetle.)
Brachycherus imperialis. Latreille.
Inhabits Brasil.

Argentatus.

Sp. 2. Argentatus.
Curculio argenteus. Gmelin, Marsh, Fabr.
Brachycherus argenteus. Latreille.
Inhabits Europe.

255. CURCULIO. Genus CCLV. Lixus. Latreille, Fabricius, Clairville.

Curculio. Linneaus, Geoffroy, Marsh, Fabricius.
Body elongate-ovate. Rostrum as broad as the head.

Lip small, entire, transverse-quadrate, conormus, narrower than the mentum.

255. CURCULIO. Genus CCLV. Lixus. Latreille, Fabricius.

Curculio. Linneaus, Geoffroy, Marsh, Fabricius.
Body elongate-ovate. Rostrum as broad as the head.

Lip small, entire, transverse-quadrate, conormus, narrower than the mentum.

256. RYNCHNUS. Curculio parrycticus. Linn.

Caraculio parrycticus. Fabricius, Latreille.
Inhabits the Phellandrium aquaticum.

256. RYNCHNUS. Curculio. Linneaus, Olivier, Latreille.

Curculio. Linneaus, Olivier, Latreille.
Body oblong, ovate, twice as long as broad. Antennae with the club three-jointed beginning at the ninth joint, or eight four-jointed beginning at the eighth joint.

Wings in all.

Tortrix.

Curculio tortrix. Linneaus, Marsham, Latreille.
Inhabits Europe.

Abietis.

Curculio abietis. Linneaus.
Inhabits Europe in the pine. It was discovered as a native of Britain by Dr Malden, who took it near Hambone, in Scotland.

Inhabits the Piusa sylvestris.

Inhabits Europe. It occurs in Britain, near Dover and Hastings.

Sp. 2. Triguttatus.
Curculio triguttatus. Marsham, Latreille.
Curculio vau of Marsham, is merely a variety of this insect.

Inhabits Europe.

258. CURCULIO. Genus CCLVI. Cryptorynchus. Illiger.

Cryptorynchus argyros. Illiger.
Inhabits Europe.

259. CURCULIO. Genus CCLIX. Clonus. Clairville, Latreille.

Rynchneus. Fabr.

Curculio. Linneaus, Geoff. Oly.
Body quadrate-ovate; thick, a little longer than broad. Abdomen large, subquadrate, a little narrower, and rounded behind. Anus not naked. Rostrum applied to the breast. Coleoptera subquadrate, the diameters nearly equal. Hinder feet not formed for leaping. Mentum conornus, subobtusolate.

Sp. 1. Er. pilinii.
Rynchneus er. pilinii. Fabr.
Cryptorynchus er. pilinii. Illiger.
Inhabits Europe.

Curculio. Linneaus, Marsham.

Inhabits the Verbuscum and Scrophularia.

Verbuscam and Verbuscam. Clairville.

Latreille supposes Rynchneus, Thebus, Scrophularia, and Verbuscam of Fabricius, to be but varieties of one species.

Genus CCLX. Orchestes. Olivier, Illiger.

Inhabits Europe.

Subdivision 2.

Antennae inserted at the base of the rostrum. Tarsi reflected to the internal side of the tibia.

261. CURCULIO. Genus CCLXI. Rhina. Latreille.

Lixus. Fabricius.

Curculio. Olivier.
Body oblong cylindric. Feet elongate, especially the
Metabellin

Barbivстроен

Lixus barbivinstris. Fabricius.
Rhina barbivinstris. Latreille.
Inhabits Africa and India.

Genus CCLXI. Calandra. Clairville, Fabricius.
Cylindricus. Olivier.

Genus CCLXII. Calandra. Clairville, Fabricius.

268. Cylindricus. Olivier.

269. Typographus. Linnaeus.

Dermestes calandra. Clairville, Fabricius.
Scolytus. Olivier.

Tarsi with entire short joints. Antennae with the club much compressed, beginning at the seventh joint, distinctly annulated. Body not linear.

Dermestes typographus. Linnaeus.

Ips typographus. De Geer.

Boscitius typographus. Fabricius, Paykull.

Ips typographus. Marsham.

Scolytus typographus. Olivier.

Tomicus typographus. Latreille.

Inhabits Europe under the bark of trees, which it gnaws into various labyrinth-like passages.

Boscitius. Paykull, Herbst.

Tarsi with entire long joints. Antennae with the club much compressed, commencing at the sixth joint; annulations not or but slightly distinct. Body linear.

Platypus cylindricus. Herbst, Latreille.

Boscitius cylindricus. Fabricius.

Scolytus cylindricus. Olivier.

Inhabits France and Germany under the bark of trees.

Subdivision 2.

Antennae with the club beginning at the ninth joint.

Genus CCLXVII. Scolytus. Geoffroy, Schaefer, Olivier, Latreille.

Hylesinus. Fabricius.

Ekkoptoaster. Herbst.

Coptoaster. Illiger.

Ips. Marsham.

Tarsi with their last joint but one bifid. Antennae with the club compressed, obovate, the apex rounded.

Scolytus destructor. Oliv. Lat.

Ips scolytus. Marsham.

Hylesinus scolytus. Fabricius.

Inhabits beneath the bark of the elm.

Genus CCLXVIII. Hylesinus. Fabricius, Latreille.

Scolytus. Olivier.

Boscitius. Paykull.

Tarsi with their penultimate joint bifid. Antennae with the club little or not compressed, ovoid, the extremity pointed.

Hylesinus crenatus. Fabricius, Latreille.

Scolytus crenatus. Olivier.

Inhabits Europe.

Division II.

Palpi very small, conic. Antennae forming a solid mass, shorter, or not much longer than the head.

Subdivision 1.

Club of the antennae commencing before the ninth joint.

Genus CCLXIV. Hylurgus. Latreille.

Ips. De Geer, Marsham.

Scolytus. Olivier.

Tarsi with their penultimate joint bifid. Antennae with the club commencing at the eighth joint, very little or not at all compressed.

Lignipatris.

Genus CCLXV. Tomicus. Latreille.

Dermestes. Linneaus.

Ips. De Geer.

Boscitius. Fabricius, Paykull.

Scolytus. Olivier.

Tarsi with entire short joints. Antennae with the club much compressed, beginning at the seventh joint, distinctly annulated. Body not linear.

Dermestes typographus. Linnaeus.

Ips typographus. De Geer.

Boscitius typographus. Fabricius, Paykull.

Ips typographus. Marsham.

Scolytus typographus. Olivier.

Tomicus typographus. Latreille.

Inhabits Europe under the bark of trees, which it gnaws into various labyrinth-like passages.

Boscitius. Paykull, Herbst.

Tarsi with entire long joints. Antennae with the club much compressed, commencing at the sixth joint; annulations not or but slightly distinct. Body linear.

Platypus cylindricus. Herbst, Latreille.

Boscitius cylindricus. Fabricius.

Scolytus cylindricus. Olivier.

Inhabits France and Germany under the bark of trees.

Subdivision 2.

Antennae with the club beginning at the ninth joint.

Genus CCLXVII. Scolytus. Geoffroy, Schaefer, Olivier, Latreille.

Hylesinus. Fabricius.

Ekkoptoaster. Herbst.

Coptoaster. Illiger.

Ips. Marsham.

Tarsi with their last joint but one bifid. Antennae with the club compressed, obovate, the apex rounded.

Scolytus destructor. Oliv. Lat.

Ips scolytus. Marsham.

Hylesinus scolytus. Fabricius.

Inhabits beneath the bark of the elm.

Genus CCLXVIII. Hylesinus. Fabricius, Latreille.

Scolytus. Olivier.

Boscitius. Paykull.

Tarsi with their penultimate joint bifid. Antennae with the club little or not compressed, ovoid, the extremity pointed.

Hylesinus crenatus. Fabricius, Latreille.

Scolytus crenatus. Olivier.

Inhabits Europe.

Division II.

Palpi very small, conic. Antennae forming a solid mass, shorter, or not much longer than the head.

Subdivision 1.

Club of the antennae commencing before the ninth joint.

Genus CCLXIV. Hylurgus. Latreille.

Ips. De Geer, Marsham.

Scolytus. Olivier.

Tarsi with their penultimate joint bifid. Antennae with the club commencing at the eighth joint, very little or not at all compressed.

Lignipatris.

Genus CCLXV. Tomicus. Latreille.

Dermestes. Linneaus.

Ips. De Geer.

Boscitius. Fabricius, Paykull.

Scolytus. Olivier.

Tarsi with entire short joints. Antennae with the club much compressed, beginning at the seventh joint, distinctly annulated. Body not linear.

Dermestes typographus. Linnaeus.

Ips typographus. De Geer.

Boscitius typographus. Fabricius, Paykull.

Ips typographus. Marsham.

Scolytus typographus. Olivier.

Tomicus typographus. Latreille.

Inhabits Europe under the bark of trees, which it gnaws into various labyrinth-like passages.

Boscitius. Paykull, Herbst.

Tarsi with entire long joints. Antennae with the club much compressed, commencing at the sixth joint; annulations not or but slightly distinct. Body linear.

Platypus cylindricus. Herbst, Latreille.

Boscitius cylindricus. Fabricius.

Scolytus cylindricus. Olivier.

Inhabits France and Germany under the bark of trees.
ENTOMOLOGY.

I 1  O

Division I.

Antennae with the club three-jointed, perfoliated.

Genus CCLXXVIII. Ditoma. Latr.

Ditoma. Herbst.

Lyctus. Fabricius, Paykull.

Ceratoma. Geoff.

Dermestes. Thunberg.

Singphoideae. Herbst.

Boleta. Marsh.

Body oval. Antennae with the last joint elongate, ovate. Maxillary palpi prominent.

Mycetophagus quadrripustulatus. Fabricius, Latreille, tulus.

Panzer, Paykull.

Boletaria quadrripustulata. Marsham.

Inhabits fungi.

Division III.

Antennae gradually thickening towards their extremities, or with a three-jointed club.

Colydium fasciatum. Hellwig, Herbst.

Inhabits Europe.

Division II.

Antennae with a nearly globose two-jointed club.

Genus CCLXVII. Cererylon. Latreille.

Lycocephagus. Herbst.

Lyctus. Fabricius, Paykull.

Body elongate. Thorax quadrate, with the hinder margin straight, contiguous with the elytra. Abdomen not pectinated.

Lyctus histeroides. Herbst.

Cererylon histeroides. Latreille.

Inhabits Europe, beneath the bark of trees.

Genus CCLXXVII. Monotoma. Herbst.

Lyctus. Fabricius, Paykull, Panzer.

Body elongate, linear. Thorax quadrate, with the hinder margin distant from the base of the elytra. Abdomen somewhat pectinated.

Inhabits beneath the bark of trees.

Corticiana taceornis. Marsham.

Inhabits beneath the bark of trees.

Family II. Mycetophagida.

Antennae eleven jointed. Mandibles little or not at all prominent.

Division I.

Antennae with the club two-jointed.

Genus CCLXXVIII. Ditoma. Latr.

Ditoma. Herbst.

Body oval, depressed. Mandibles little or not at all prominent.

Ceratoma. Geoff.

Dermestes. Thunberg.

Singphoideae. Herbst.

Boleta. Marsh.

Body oval. Antennae with the last joint elongate, ovate. Maxillary palpi prominent.

Mycetophagus quadrripustulatus. Fabricius, Latreille, tulus.

Panzer, Paykull.

Boletaria quadrripustulata. Marsham.

Inhabits fungi.

Division III.

Antennae gradually thickening towards their extremities, or with a three-jointed club.

Inhabits Europe under the bark of trees.

**Subdivision 2.**

Tarsi with the first joint longer than the second. Palpi very short, the maxillary ones but little or not at all prominent. Antennae as long as the thorax or less.

**Genus CCLXXXI. Latridius.** Herbst.

- **Ips.** Olivier.

**Corticaria.** Marsham.

- **Derastes.** Fabricius, Paykull.

Antennae with the second joint larger than the third.

**Sp. 1. Porcatus.**

- Latridius minutus. Latreille.
- Derastes marginatus. Paykull.

Inhabits houses in Europe.

**Genus CCLXXXI. Silvanus.** Lateille.

**Tenebrio.** De Geer.

- **Derastes.** Fabricius, Panzer.
- **Ips.** Olivier.
- **Colydium.** Paykull, Herbst.
- **Corticaria.** Marsham.

Antennae with the second and following joints to the eighth joint nearly equal.

**Sp. 1. Unidentatus.**

- Silvanus unidentatus. Latreille.
- Derastes unidentatus. Fabricius.
- Ips unidentatus. Olivier.
- **Colydium unidentatum.** Paykull.
- **Colydium planum.** Herbst.

Inhabits Europe under the bark of trees.

**Genus CCLXXXVI. Silvanus.** Lateille.

- **Tenebrio.** Fabricius, Herbst.
- **Corticaria.** Marsham.

Antennae with the second joint not longer than the following joint. Maxillary palpi prominent. Body elongate, narrow. Antennae with the three last joints rather thicker.

**Genus CCLXXXIII. Meryx.** Latreille.

- **Sp. 1. Rugosa.**

Inhabits the East Indies.

**Division IV.**

Antennae cloven-jointed. Mandibles prominent or exserted.

---

**Subdivision 1.**

Mandibles small. Body long and linear.

**Genus CCLXXXIV. Lyctus.** Fabricius, Paykull.

- **Ips.** Olivier.

**Bitoma.** Herbst.

**Corticaria.** Marsham.

Antennae with a two-jointed club. Thorax long and linear.

- **Sp. 1. Oblongus.**
  - Lyctus oblongus. Latreille.
  - Lyctus canaliculatus. Fabricius.
- **Ips oblongus.** Olivier.

**Bitoma unipunctata.** Herbst.

**Corticaria oblonga.** Marsham.

Inhabits Europe in old wood.

**Subdivision 2.**

Mandibles large. Body elongate, much depressed, nearly equally broad.

**Genus CCLXXXV. Trogosita.** Fabricius, Olivier.

- **Sp. 1. Mauritanica.**
- **Platyderes.** Geoffroy.

Thorax almost quadrate, separated from the abdomen by a remarkable interval. Antennae moniliform, shorter than the thorax, compressed towards the apex. Labrum exerted, coriaceous, small, hairy in front.

**Sp. 1. Mauritanica.**

- **Platyderes.** Geoffroy.

Inhabit Europe. Dr Leach has seen it alive in a box of insects brought from Pará in the Brasils.

**Tribe VI. Cucujides.**

Body oblong and much depressed. Head not globose. Palpi filiform or thicker towards their extremities. Antennae of the same thickness throughout, all eleven-jointed. Thorax almost quadrate, generally dentate or angulated.

**Division I.**

Antennae moniliform, shorter than the body.

**Genus CCLXXXVI. Parandra.** Latreille.

- **Isocerus.** Illiger.
- **Attelabus.** De Geer.
- **Tenebrio.** Fabricius, Herbst.

- **Sp. 1. Levius.**
  - Parandra levius. Latreille.
  - Tenebrio brunneus. Fabricius.
  - Tenebrio purpurascens. Herbst.

Inhabit America.

**Genus CCLXXXVII. Cucujus.** Fabricius, Olivier.

- **Paykull.**
- **Cantharis.** Linneaus?

Labrum prorect, very apparent. Palpi with their last joint obconic, truncate. Tarsi short. Lip bifid.

- **Sp. 1. Depressus.**
  - Cucujus depressus. Paykull, Olivier, Latreille, Fabricius.
- **Cantharis sanguinolenta.** Linneaus?

Inhabit Sweden and Germany.

---

*The genus *Dacyerus* of Brongniart is akin to this genus:*
ENTOMOLOGY.

DIVISION II.
Antennae as long as the body, often longer, composed of elongate cylindrical joints.

Genus CCLXXXVIII. Uleiota. Latreille.
Cerambyx. Linnæus.
Brontis, Fabricius.
Cucujus, Olivier, Herbst.

Labrum nearly, very apparent. Palpi terminated by an almost conic pointed joint. Tarsi short.

Sp. 1. Flavipes.
Cerambyx planatus. Linnæus.
Uleiota flavipes. Latreille.

tincto-collis. Olivier, Paykull.

Inhabits Europe, beneath the bark of dead trees.

DIVISION III.
Head not gradually produced into a rostrum. Tarsi strong beneath.

Subdivision 1.
Antennae filiform or setaceous, or slightly thickening towards their extremities. Maxillae with no horny hook on their internal sides.

Tribes VII. Cerambycidae.
Lip much widened at its extremity, cordiform. Body elongate. Antennae long, generally inserted in a notch in the eyes.

Family I. Prionida.
Labrum very small, or almost none.

DIVISION I.
Antennae moniliform, short.
Genus CCLXXXIX. Spondylis. Fabricius, Olivier, Latreille.

Attelaus. Linn.
Cerambyx. De Geer.

Palpi with the last joint nearly obconic. Body convex. Tarsi with the penultimate joint distinctly bispinose. Thorax almost orbicular, without border or teeth.

Attelaus hypoptoides. Linn.

Inhabits Europe, at the roots of the pine.

DIVISION II.
Antennae pectinated or serrated, in all longer than the thorax.

Genus CCX. Prionus. Geoffroy, Fabricius, Olivier, Latreille.
Cerambyx. Linnæus, Marsham.

Thorax with the sides gently sloping, dentated. Antennae serrated, a little shorter than the body; of the male twelve, of the female eleven-jointed.

Cerambyx coriarius. Linn.
Prionus coriarius. Latreille, Fabricius, Olivier.

Inhabits Europe.

Family II. Cerambycidae.
Labrum very apparent, of various sizes. Antennae inserted in a notch in the eyes.

DIVISION I.
Head vertical. Palpi almost filiform.

Genus CCXCI. Macropus. Thunberg.
Prionus. Olivier.
Cerambyx. Linnæus.
Lamia. Latreille.

Body much depressed. Thorax with a movable spine on each side, placed on a tubercle. Anterior feet of the male very long.

Sp. 1. Longimanus.
Prionus longimanus. Olivier.
Lamia longimanus. Latr.
Cerambyx longimanus. Linn.

Inhabits Brazil.

Genus CCXCII. Lamia. Leach.
Lamia. Latreille, Fabricius.
Cerambyx. Linnæus, Marsham, Fabricius.

Antennae ten-jointed, longer than the body. This genus is divided into sections.

A. Body depressed. (Lamia, Fabricius.)
Lamia edulis. Fabricius, Latreille.
Cerambyx edulis. Linnæus, Marsham.

Inhabits Europe.

B. Body not depressed. (Lamia, Cerambyx, Fabricius.)
Cerambyx nebulosus. Fabricius, Marsham.

Lamia nebula. Latreille.

Inhabits Europe.

Sp. 3. Textor.
Lamia textor. Fabricius, Latreille.

Inhabits Europe.

C. Body linear. Thorax not spined at the sides.

(Saperda, Fabricius.)
Sp. 4. Oculata.
Cerambyx oculatus. Marsham.

Saperda oculata. Fabricius.

Lamia oculata. Latreille.

Inhabits Europe.

Genus CCXCIII. Saperda. Leach.
Cerambyx. Marsham.

Cerambyx linneus-collis. Marsham.
Saperda lineus-collis. Leach, Zool. Misc. vol. i.

Inhabits England.

DIVISION II.
Head nutant. Palpi with the last joint thicker than the others.

Genus CCXCIV. Cerambyx. Linnæus. Fabricius, Linnæus, Marsham, &c.

Stenocorus. Fabricius.

Antennae longer than the body. Palpi with the last joint obconic, compressed. Thorax with a spine on each side.

Sp. 1. Moschatus. (Musk cerambyx.)
Cerambyx moschatus. Linn. Fabricius, Latreille, &c.

Inhabits Europe, emitting, whilst alive, a fine smell, resembling the flavour of rose.

Genus CCXCV. Stenocorus. Fabricius.
Cerambyx. Latreille.

Palpi with the last joint obtriginate. Thorax without spines.

Stenocorus spinicornis. Fabricius.
Cerambyx spinicornis. Latreille.

Genus CCXCVI. Clytus. Fabricius.
Cerambyx. Linnæus.

5
ENTOMOLOGY.

Labial palp with the last joint oblongate. Thorax without spines, glabrous. Antennae shorter than the body. Hinder thighs clavate.

Cerambyx arietis. Linn.
Clytus arietis. Fabricius.
Callidium arietis. Latreille.
Inhabits Europe.

297. Callidium.
Genus CCXXVII. Callidium. Fabricius, Latreille.
Cerambyx. Linn. Marsham.
Labial palp with the last joint oblongate. Thorax orbicular, depressed, or but little convex. Antennae setaceous, as long as the body. Hinder thighs abruptly clavate.

Callidium violaceum. Fabricius, Latreille.
Inhabits Europe.

298. Necydalis.
Leptura. Geoffroy.
Molorchius. Fabricius.
Elytra subulated, not entirely covering the wings and abdomen.

Necydalis rufa. Fabr. Latr.
Inhabits Europe.

299. Molorchius.
Genus CCXXIX. Molochius. Fabricius.
Necydalis. Linn. Marsham, Latreille.
Elytra abbreviated.

Necydalis major. Linn.
Molorchius umbellatum. Fabr.
Inhabits Europe.

Family III. Lepturida.
Labrum very apparent. Antennae inserted between the eyes.

300. Leptura.
Genus CCC. Leptura, of authors.
Thorax not spinous on each side.

Sp. 1. Elongata.
Leptura elongata. Fabricius, Latreille, Marsham.
Inhabits Europe.

301. Rhagium.
Genus CCCI. Rhagium. Fabricius.
Leptura. Latreille, Marsham.
Thorax with a spine on each side.

Sp. 1. Inquisitor.
Rhagium inquisitor. Fabricius.
Inhabits Europe.

Tribe VIII. Criocerides.

Family I. Sagraida.

302. Megagalopus.
Genus CCCII. Megalopus. Fabricius, Latreille.
Antipus? De Geer.
Antennae almost serrated, inserted at the internal margin of the eyes, shorter than the thorax. Palpi filiform, terminated by an elongate, very pointed, and conic joint. Thorax almost quadrate. Body little lengthened.

Crust.et Ins. 3. tab. 11. fig. 5.
Inhabits South America.
Genus CCCIII. Orsodachna. Latreille.
Crioceris. Geoffroy, Fabricius, Paykull, Panzer.
Antennae simple, inserted before the eyes, as long as the thorax or less. Maxillary palp thick and truncate at their extremities. Body long. Thorax elongate. Eyes globose.

Crioceris cerasi. Fabricius.
Orsodachna chlorotica. Latreille.
Inhabits Sweden, Germany, and France.
Alurnus. Olivier.
Tenenio. Sulzer.
Antennae simple, inserted before the eyes. Palpi filiform, the last joint somewhat ovate, the apex acute. Eyes lunate. Hinder feet, especially the thighs, very thick. Body elongate.

Sp. 1. Femorata.
Alurnus femoratus. Olivier.
Inhabits Africa.

Family II. Criocerida.

Mandibles bifid or notched at their extremities.

Leptura. Linn. Marsh.
Antennae with elongate cylindric joints, those of the base obconic. Eyes not notched. Abdomen elongate-triangular. Hinder thighs thick.

Donacia micans. Hoppe.
Leptura micans. Marsh.
Inhabits Europe.

* Hinder thighs dentated.

Sp. 2. Simplex.
Leptura simplex. Marsham.
Inhabits Europe.

Leptura. Linn. Marsham.
Auchenia. Marsham.
Antennae moniliform, with the exception of the basal joints which are globose. Eyes notched. Neck distinct. Abdomen quadrate.

Crioceris meridigera. Latreille.
Auchenia meridigera. Fabricius.
Auchenia meridigera. Marsham.
Chrysomela meridigera. Linn.
Inhabits the white lily.

Tribe IX. Chrysomelides.

Lip not cordiform. Maxillae with their external division resembling a biarticulate palp. Body more or less ovoid or oval. Thorax transverse, or not longer than broad.

Family I. Castorida.

Palpi very small. Antennae inserted near each other between the eyes, at a distance from the mouth.

Division I.

Body elongate. Thorax almost quadrate.

Genus CCCVII. Alurnus. Fabricius, Latreille.
ENTOMOLOGY.

Metabolla. Hispa. Olivier. 
Body not spinose. Mandibles terminated by a strong hook.

Crici is. Olivier. 
Body spinose. Mandibles with their points bidentate.

Atra. Hispa atra. Linn. Fabricius, Olivier, Panzer.
Inhabits Europe. This species has been introduced into the British Fauna on dubious authority.

DIVISION II.

Genus CCCCIX. Himatidium. Illiger.

Imatidium. Fabricius, Latreille.
Antenne entirely exerted, cumbie. Body nearly square.

Himatidium leaenamum. Latreille.

Antenne thicker towards their extremities, their base concealed by the thorax. Body nearly orbiculate.

Cassida viridis. Marsham, Illiger.
Inhabits Menita sylvestris.

FAMILY II. Galerucida.

Maxillary palpi very apparent. Antenne inserted very near to each other, between the eyes, towards the middle of the face.

DIVISION I.

Feet not formed for leaping.

Genus CCCXI. Adorium. Fabricius, Latreille.

Oides. Weber.
Palpi with the last joint but one dilated, the last short, nearly cylindrical, truncate. Antenne almost orbicular. Elytra with their exterior margin arcuated.

Adorium bipunctatum. Fabricius, Latreille.
Oides bipunctata. Weber.
Inhabitants Eastern India.

Palpi with the two last joints very slightly different in size, the last conic. Antenne shorter than the body, the joints obcomb, the second joint half the length of the third.

Chrysomela tanaceti. Marshan.
Galeruca tanaceti. Latreille, Fabricius.
Inhabitants Europe.

Galeruca. Latreille, Fabricius.

Crici is. Fabricius.
Palpi with the two last joints not very different in size, the last joint conic. Antenne shorter than the body, the joint obcomb, with the second and third joints shorter than the fourth joint.

Crici is nigricornis. Fabricius.
Galeruca nigricornis. Latreille.
Inhabitants Europe.

Chrysomela alni. Marshan.
Galerucia alni. Latreille, Fabricius.
Inhabitants Europe.

Crioceris. Fabricius.
Palpi with the two last joints nearly equal in size, the last conic. Antenne as long as the body, the joint cylindric, elongate.

Sp. 1. Flavipes.
Luperus flavipes. Latreille.
Crioceris flavipes. Fabricius.
Inhabitants Europe.

Sp. 2. Rupipes.
Crioceris rupipes. Fabricius.
Inhabitants Europe.

DIVISION II.

Hinder feet formed for leaping, the thighs being incrassated.

Genus CCCXV. Haltica.

Altica. Geoffroy, Olivier, Panzer, Latreille.

Crioceris. Fabricius.

Lema. Fabricius.

Galerucia. Fabricius.
Antenne with the second joint generally a little shorter than the second. * Body ovate.

Altica oleracea. Latreille, Panzer.

Galleracea oleracea. Fabricius.
Inhabitants Europe. ** Body nearly orbiculate.

Sp. 2. Testacea.

Galeruca testacea. Fabricius.

Altica testacea. Latreille.
Inhabitants Europe.

FAMILY III. Chrysomelida.

Maxillary palpi very apparent. Antenne inserted before the eyes, gradually thickening towards their points. Head nutant, forming an obtuse angle with the thorax.

DIVISION I.

Mandibles short, obtuse, truncated, or terminated by a very short point. Antenne with the four last joints globose or turbinated.

Subdivision 1.

Antenne with the four last joints turbinated. Body hemispheric or oval. Thorax transverse.

Genus CCCXVI. Panopsia. Olivier, Latreille.

Maxillary palpi terminated by a securiform joint.

Body hemispherical.

Panopsia Australasiae. Olivier.
Inhabitants New Holland.

Maxillary palpi terminated by a transverse joint shorter than the one before it. Sternum with its middle produced into a horn.

Chrysolena punctatissima. Fabricius.

Doryphora punctatissima. Illiger, Latreille.

318. Chry-

Metabolla. Palpi terminated by two joints of nearly an equal length, the last almost ovoid truncate, or nearly cylindric. Sternum not produced.

* Thorax with the sides incrassated, as if margined; Body ovate-quadrature.

Chrysomela Banksii. Fabricius, Latreille, Marsham.
Inhabits Europe.

* Thorax with the sides not incrassated. Body ovate quadrature.

Chrysomela litura. Fabricius, Latreille, Marsham.
Inhabits the broom.

* Body elongate-ovate-quadrature.

Chrysomela marginella. Fabricius, Latreille.
Inhabits Europe.

Subdivision 2.
Antennae with the four last joints semi-globose almost forming a club. Body elongate-quadrature. Thorax as long as broad.

Phasociris. Latreille.
Chrysomela. Marsham, Hellwig.
Palpi short, thicker at their middle, the last joint short-obconic.

Helodes phellandrii. Paykull, Fabricius.
Prosociris phellandrii. Latreille.
Inhabits Europe.

Helodes violacea. Fabricius.
Chrysomela beccabunga. Hellwig, Marsham.
Inhabits Europe.

DIVISION II.
Mandibles abruptly arcuated, terminated by a very strong point. Antennae with the four last joints elongate, compressed, reversed-conic; the last long almost elliptic; and terminated by a point resembling an additional joint.

Maxillary palpi terminated by a large joint, nearly ovoid.

Colaspis Surinamensis. Latreille.
Inhabits Surinam.

Family IV. Cryptocoephalida.
Maxillary palpi very apparent. Antennae inserted before the eyes. Head vertical.

DIVISION I.
Palpi with the last joint thick, ovoid. Body nearly ovoid.

Cryptocoephalus. Olivier, Geoffroy.
Thorax with a very convex back, which is gibbose.

Cryptocoephalus vitiis. Fabricius.
Eumolpus vitiis. Fabricius, Latreille.
Inhabits Europe on the vine.

DIVISION II.
* Palpi with the last joint conic-cylindric. Body short-cylindric.

Antennae simple, filiform, about the length of the body.

Chrysomela sericea. Linn.
Cryptocoephalus sericeus. Fabricius, Olivier, Marsham.
Inhabits the flowers of the Dandelion.

Genus CCCXIII. Clythra. Lacharting, Fabricius, Olivier, Latreille.
Chrysomela. Linn.
Melolontha. Geoffroy.
Cryptocoephalus. Marsham.
Antennae, short, serrated, exserted. Palpi alike.

Clythra quadripunctata. Fabricius, Latreille.
Cryptocoephalus quadripunctatus. Marsham.
Chrysomela quadripunctata. Linn.
Inhabits Europe.

Clythra. Fabricius, Olivier.
Labial palpi furcate. Feet contractile. Antennae short, serrated, lodged in a rim of the thorax.

Clythra monstrosa. Fabricius.
Clamyx monstrosa. Latreille.

Subdivision I.
Antennae a perforated club. Maxillae with their internal side unguliculated.

TRIBE X. Erotylides.

Family I. Erotylida.
Palpi all terminated by large, semilunar, or securiform joints.

DIVISION I.

Body ovate or oval.

Erotylus gibbosus. Fabricius, Latreille.
Genus CCCXXVI. Agathus. Fabricius.
Erotylus. Latreille.
Body hemispheric.

DIVISION II.

Body short-ovate, the back elevated in the middle.

Thorax with the middle of the hinder margin dilated into an angle.

Body oval.

Silphia russica. Linn. Marsham.
Inhabit dead trees and fungi.
ENTOMOLOGY.

FAMILY II. Phalacridae.

Maxillary palpi filiform, or thicker towards their extremities.

DIVISION I.

Tarsi with the penultimate joint, bilobate. Body not contractile into a ball.

Subdivision 1.

Body linear.

Subdivision 2.

Body hemispheric.

DIVISION II.

Tarsi with the joints entire. Body nearly globose, contractile into a ball.

SECTION IV. Trimeria.

Tarsi all three-jointed.

TRIBE I. Coccinellides.

Antenne shorter than the thorax. Maxillary palpi terminated by a very large subcuneiform joint. Body hemispheric. Thorax transverse, the hinder margin arcuated.

Coccinella bicoccina. Fabr. Inhabits Europe.

Thorax (even behind) narrower than the elytra. Body hemispheric, approaching to ovate.

TRIBE II. Endomychides.

Antenne longer than the thorax. Maxillary palpi not terminated by a large joint. Body more or less ovoid. Thorax almost quadrangular.

Inhabits eastern India.

Genus CCCXXXVI. Endomychus. Payk. Fabr. 336. End. Chrysomela. Linn. De Geer. Tenebrio. Marsh. Antenne with the greater portion of their joints very short, nearly cylindric; the ninth longer than the one before it; the last with the apex truncate or obtuse. Palpi with their extremities thicker. Thighs not abruptly clavate. Body ovate. Thorax short, with the base gradually enlarging from the apex, not narrowed behind. Mandibles with their points distinctly bifid or bidentate.

SECT. V. Dimera.

Tarsi with two joints.

TRIBE I. Pselaphides.

Elytra short. Antenne eleven-jointed. Mandibles in all.

* The genus Dypseaer of Andersch has nine joints in its antenne, and a clypeiform thorax shielding the head.

† The British species are to form the subject of a paper for the Linnean Society, by Mr Stephens, an acute entomologist.
ENTOMOLOGY.

Antennae with the two or three last joints larger than the rest, the extreme joint ovate. Labial palpi much shorter than the maxillary ones, the last joint very long, cylindric. Maxillary palpi much proctored. Tarsi with one nail.

Impressus.
Inhabits Europe. It sometimes occurs in Bettersea fields amongst the roots of grass.

Genus CCCXXXIX. Chenium. Latr.
Antennae with the ten first joints nearly equal, lenticular; the last joint, semiglobose. Palpi very small, not exserted. Tarsi with two nails.

Inhabits France.

 Tribe II. Clavigerides.

Genus CCCXL. Claviger. Preysler, Illiger, Latreille.
Antennae with the middle joints semiglobose, the last larger, short-cylindric. Palpi very small. Tarsi with one nail.

Order IV. Strepsiptera.

Order Strepsiptera. Kirby.

Order Hymenoptera. Rossi.
We are indebted to Rossi for the discovery of the type of this highly interesting order of insects. The insect discovered by this author was denominated Xenops Vesparum, and was by him, without hesitation or comment, assigned a place among the hymenopterous insects, next to Ichneumon. The Rev. William Kirby, who first called the attention of entomologists to a British insect named Stylops Melitae, was the first author who observed that it possessed characters different from those of any of the established orders of insects; and this opinion has since confirmed by Mons. Latreille, who, in the end of his Genera Crustaceorum et Insectorum, thus expresses himself: "Insectum prorus singulare (Stylops melitae, Dom. Kirby), a Dom. Brebisson accepit. Systema Entomologiae perturbare videtur, cum ex omnibus ordinibus repellatur. Xenops Vesparum Rossi animal precedunt affini et animal pariter aequantis. Tempus decanus et dies alteri incertum afferant." The time he predicted has arrived; and it has been lost to the lucid genius of Kirby to substantiate and to characterise this order, which he has done in a paper published in the 11th volume of the Transactions of the Linnean Society, from which we shall extract a brief history of the order, genera, and species.

"Characters of the Order.

"Body oblong or linear-oblong, somewhat cylindric, covered with a herry integument.

"Head sessile, broader than the trunk, transverse and large. Mouth with no visible labrum, labium, or maxillae. Mandibles two, conical, elongate, linear, very narrow; the apex acute, foricate, inserted under the head at the base of the palpi, which are two, bia-

We have considered it as unnecessary to give the detailed character; we must therefore refer to Mr Kirby's paper, Lin. Trans. vol. xi. p. 109-119.
ENTOMOLOGY.

It the be confined, having been made from the recent animal, to the celebrated author of the *Monographia Apum Angliae*, with the following statement, which we have extracted from his letter to Mr Kirby.

"Your having met with the remains of *Strangalia* in foreign *Passeridae* made me determine to look for them in those of this country; and I have the pleasure to find one in a species of *Poltites* that is here very abundant. The abdomen of this *Poltites* is so distorted by them, that I have no difficulty in knowing them when on the wing. Taking them with the gauze forceps, bringing them into a close room, and permitting them to fly to the windows, I caught them again with a wine-glass and a card, fed them with sugar, and thus preserved them till their parasites were disclosed. I had not the pleasure to see them emerge, but I found them soon after. I obtained four in this way, and brought several nests of the *Poltites* into the house, taking them in the night, when all the inhabitants were at home, in the hopes of obtaining more; but I got no living ones.

"All that I know of this animal, was picked up in a few days that I passed at my little place at Newberry. In feeding, the head of the larva is near the base of the abdomen of the wasp, as I found by dissection. When the feeding state is passed, it is easy to conceive that it turns, and with its flattened head separates the membrane which connects the abdominal scutum, and protrudes itself a little way, accurately closing the aperture, which is just large enough to admit it. This time the wasp is active, and associates with its companions. When just protruded, the head of the larva is of a pale brownish colour; by degrees it assumes a rounder form, and becomes almost black.

The pupa state ensues, but I suspect that only the part exposed to the air, and that immediately under the pressure of the abdominal ring, becomes hard.

"The four I took were all alike, and I concluded that they were males, from the circumstance of their vibrating their wings, which several lepidopterous insects of that sex do likewise. Be assured, that this indicates eager desire. So my insect, which I confined under a watch-crystal, coursed round its prison, with surprising trepidation, as long as it lived, which was but a few hours."

*Sp. 2. Rossii.* Deep-black; branches of the antenna compressed; tarsi brown.

*Xenops vesparum.* Rossii.

*Xenops rossii.* Kirby.

Inhabits Polistes Gallicus, in Italy.

Body black, smoky. Head small. Palpi with the first joint short, rounded; the second elongate, compressed. Antennae scarcely longer than the head, though compressed, as if ensiform. Tarsi (four) brown, white beneath.

"Rossi, in his description, which, extraordinary as he deemed his insect, appears to have been drawn up from a very cursory and inaccurate survey of it, mistakes the mandibles for setae, and seems not to have traced them to their point of insertion under the head, since he merely says, *Labiium breve, medio setigera.* He takes no notice of the eyes being placed in a footstalk or pillar. The elytra he regards as an appendage of the thorax, something similar to the haltare or poises of the *Diptera."

Mr Kirby has never seen *Xenops Rossi*, but has merely copied Rossii's account. Upon comparing the descriptions of the two species, we find that they not only differ in colour, but also in the length of the first joint of the palpi compared with the second, and in the form of the branches of the antennae. Rossi makes no mention of the minute white dots which render those of *Xenops Pekki* so very remarkable; we therefore think, that Mr Kirby is fully justified in considering them as distinct. Should the proportion of the joints of the palpi be found in nature to be the same as expressed in Rossii's figure, these animals cannot be referred even to the same genus, but must constitute a new one.

**ORDER V. DERMAPTERA.**

**Order Dermaptera.** Kirby.

**Order Coleoptera.** Linn. Marsh.

**Order Orthoptera.** Latr. Linn.

**Characters of the Order.**

Elytra somewhat crustaceous and abbreviated, of a square form; the suture straight. Wings membranaceous, externally coriaceous, large, folded transversely and longitudinally. Anus armed with a forceps, which is horny and moveable. Body linear depressed. Antennae inserted before the eyes, composed of from twelve to thirty joints; the first articulation largest, the second very small, the others short, oblong, or nearly globose. Mandibles with their points bidentate. Palpi filiform, terminated with a very obscure tubercuiform little body or spine. Tarsi three-jointed, villos beneath. Eyes triangular-orbicular, and but little prominent.

**Observation.** The genera are founded on the number of joints in the antenna.

Antennae composed of fourteen joints. *Sp. 1. Auricularia.* Forceps at the base internally dilated, and a little beneath with a tooth on each side. Elytra yellowish-brown, with the disc darker.

*Forficula auricularia* of authors.

Inhabits Europe. Mr Marsham has considered the sexes of this insect as two species, under the names *auricularia* and *neglecta*.

**Genus CCCXLIV. Labia.** Leach. 344. Labia 344. Labia Minor.

Antennae twelve-jointed. *Sp. 1. Minor.* Forceps denticulated within. *Forficula minor.* Fabr. Pauz. Inhabits Europe. The forceps of the male are somewhat larger than that of the female, which character Mr Marsham has considered as specific.

**Genus CCCXLV. Labidula.** Leach. 345. Labidula 345. Labidula Gigantea.

Inhabits Europe. It was discovered to inhabit Britain, by the Rev. William Bingley, who observed them on the sea-coast, near Christchurch, Hampshire, where they occurred in great abundance.

* We shall transcribe this part of Mr Kirby's paper, with the exception of the terms; which we shall change for those adopted in this article.
ORDER VI. ORTHOPTERA.
Class Uallonata. Fabr.
Order Hemiptera. Linn.

Characters of the Order.
Elytra coriaceous, the internal margin of one overlapping the same margin of the other. Wings membranaceous, the anterior margin coriaceous, longitudinally folded. Palpi short. Body elongate, narrow. Tarsi with four or three, very rarely with five joints.

TRIBE I. Mantidae.
Elytra and wings horizontal; the latter simply longitudinally folded. Tarsi five-jointed. Body somewhat cylindrical or linear. Feet not formed for leaping.

FAMILY I. Phasmida.
Anterior feet not raptorial. Thorax composed of two segments.

GENUS CCCXLVI. PHASMA. Licht. Fabr. Latr.
Leach.
MANTIS. Linn. De Geer, Oliv.
SPECTRUM. Stoll. Lam.
Body cylindrical, filiform, winged. Thorax cylindrical, second segment much longer than the first. Feet simple.

Violascens.
Sp. 1. Violascens. Green, with the external edge of the elytra yellowish; the wings, with the exception of the coriaceous margin, violet; the four hinder thighs spiny beneath.

Inhabits New Holland.

GENUS CCCXLVII. SPECTRUM. Stoll. Lamarck.
Leach.
PHASMA. Fabricius, Latreille.
Body cylindrical, filiform, without wings. Feet simple.

Rossiina.
Sp. 1. Rossium. Body green, or ash-coloured brown, somewhat obliquely granulated, with a dorsal carina; feet filiform, angulate-striate; thighs towards their joints beneath with one tooth.

PHASMA rossii. Fabricius, Latreille.

Inhabits Italy and the southern parts of France.

GENUS CCCXLVIII. PHYLLEUM. Illiger, Latreille.
MANTIS. Linn. Fabr. Oliv.
PHASMA. Lich. Lam.
SPECTRUM. Stoll.
Body oblong, very much depressed, with elytra and wings. Abdomen oval or elliptical membranaceous.

Sicifolium.

Mantis sicifolia. Lin. Fabr. Donovan, Nat. Hist. of the Insects of India, No. 3. fig. 3.

Inhabits the Maloune Isles.

FAMILY II. Mantida.
Anterior feet raptorial. Thorax composed of one segment.

GENUS CCCXLIX. EMPEMA. Illig. Latr.
Antennae of the male pectinated. Head produced into a horn. Four hinder feet having their knees adorned with leaf-processes.

Mendica.

Antennae in both sexes simple. Head without an horn. Legs all simple.

Sp. 1. Religiosa. Pale green, somewhat linear; thorax half the length of the elytra, three times longer than broad. Back, with the exception of the anterior part, longitudinally carinate. Lateral margins yellowish, denticulated. Elytra linear, glaucous transparent green, the exterior margin yellowish. Wings of the same colour with the elytra, but paler and more transparent, the tips brownish. Anterior legs with denticulated coxae. Anterior thighs yellowish within, denticulated at the base beneath; the spines with black tips.

Mantis religiosa. Linn. Latr.
Le Mante. Geoffroy.

Mantis oratoria var. s. Fabricius.

Gryllus religiosus. Scopoli.

Inhabits the commons and wastes of southern Europe.

TRIBE II. Acetidae.
Elytra horizontal. Wings longitudinally folded, often produced beyond the elytra. Tarsi three-jointed. Hinder feet formed for jumping.

FAMILY I. Gryllotalpida.
Antennae not longer than the thorax. Anterior feet compressed, formed for digging. Oviduct not exerted.

GENUS CCL. GRYLLALTA. RAY. Latreille.

Gryllus (Acheta) Linn.

Acheta. Fabr.

Antennae setaceous, composed of a vast number of joints, (beyond sixty.) Anterior tibiae and tarsi formed for digging; two first joints of the tarsi very large, dentiform. Hinder feet little formed for jumping.

Sp. 1. Vulgaris. Above fuscos, ferruginous-yellow, yellowish beneath; anterior tibia quadridentate; wings twice the length of the elytra.

Gryllus gryllotalpa. Linn.

Acheta gryllotalpa. Fabricius.

Gryllotalpa vulgaris. Latreille.

Inhabits Europe. The male sings in the evening by rubbing the elytra together.

Inhabitats Cayenne.

This species has been confounded with G. vulgaris in several cabinets.

GENUS CCLII. TRIDACTYLS. Olivier, Latr.

Acheta. Coquebert.

Antennae moniliform, (very short), ten-jointed. Anterior tibiae with their joints only spinous. Hinder feet well calculated for leaping.

Sp. 1. Paradoxus. Pale luteous; thorax pale fuscos, the sides pale luteous; elytra half the length of the abdomen, brown, hyaline externally with white tips; wings a little longer than the abdomen, with their base white, then pale brown, transversely striated.

Inhabits Guinea. It is the Acheta digita. Coquebert, tab. 21. fig. 3.

FAMILY II. Acetida.

Feet not formed for digging. Oviduct exerted.

Antennae longer than the thorax.

GENUS CCLIII. ACHETA. Fabr.

Gryllus campestris. Linn. Latr.

Acheta campestris. Fabricius.

Inhabits the temperate parts of Europe. Is not very common in Britain.
ENTOMOLOGY.

TRIBE III. LOCUSTIDAE.

Gryllus (tettigonia), Linn. Hinder feet twice the length of the body. Oviduct exserted.

Viridines.

Locusta viridissima. Fabricius, Latreille. Gryllus viridissimus. Linn. Inhabits Europe. In the autumn, the perfect insect may be found in great plenty near London.

TRIBE IV. GRYLLIDES.

Elytra and wings oblique. Hinder feet formed for jumping. Tarsi with three joints. Antenne filiform or ensiform. Oviduct not exserted.

FAMILY I. GRYLLIDAE.

Wings not covered by the scutellum.

Gryllus (Locusta), Linn. Acrystum. De Geer, Olivier.

The species are numerous, but are little known; one species having been confounded with another.

Genus CCCCLVII. Gryllus. Fabricius, Panzer.

Gryllus (Locusta), Linn. Mandibles blue.

Antennae filiform, or terminated in a club. Hinder legs not, or scarcely, longer than the body.

This genus comprehends a vast number of species.

This species has been taken in Britain occasionally; but in the year 1748 it appeared in several irregular flights, in several parts of Europe, (as we have mentioned in our list of entomological writers,) and visited England, but they perished in a very short time, before they did much harm.

Of all the insects which are capable of adding to the calamities of the human race, locusts seem to possess the most formidable powers of destruction. Legions of these voracious animals, of various species, are produced in Africa, where the devastations they commit is almost incredible. The air is darkened by their numbers; they carry desolation with them wherever they pass, and, in the short space of a few hours, are said to change the most fertile provinces into a barren desert.

Some of the species serve as food, and are eaten fresh as well as salted. In the latter state they are constantly exposed to sale in the Levant; but the quantity of nutritious matter is said to be very small.

FAMILY II. ACYRIDEA.

Wings covered by the scutellum.

Drydom.

Acrydom (Bulla). Linn. Tetrix. Latreille.

Subulata. Latreille. Acyrideum subulatum. Fabricius, Olivier.

Tetrix subulata. Latreille. Inhabits Europe. It is found in hot banks, and is subject to some variation in colour.

The species of Acyrideum are but little understood. We seem to possess three very distinct indigenous species, all varying in size, sculpture, and colour.

ORDER VII. DICTUOPTERA.

Order HEMIPTERA. Linn.

Class Ulonata. Fabricius.

Order ORTHOPTERA. Latreille.

Order Dictuoptera. Leach.

Characters of the Order.

Elytra coriaceous, nervose, decussating each other. Wings membranaceous, with a few longitudinal folds. Maxillary palpi elongate. Body depressed, oval, or somewhat orbicular. Tarsi with five joints.

Elongate-ovate, ferrugineous brown.

Thorax semicircular, truncate before.

Inhabits North America. Is common in Europe in houses, but is not indigenous to that quarter of the globe.

The genus Blatta may be defined, (as it now stands,) to be a general reservoir for all insects, agreeing with the character of the order. Much might be done towards elucidating this hitherto neglected part of entomology; and we trust that some entomographer, who has time, will devote some share of his attention to the examination of the genera and species.

ORDER VIII. HEMIPTERA.

Order HEMIPTERA. Linn. Lamarck, Cuvier, Leach.

Class RHYNKOTA. Fabricius.

Order Hemiptera, Section 1. Heteroptera. Latr.

Characters of the Order.

Rostrum attached to the anterior extremity of the head. Elytra somewhat crassate to coriaceous with the apex membranaceous, placed in an horizontal direction; one decussating the other. Thorax with the first segment, (which bears the feet,) larger than the following one. Haustellum with three sete. Ocelli or little eyes, two, one obsolete.

Obs. The metamorphosis of all the order is semi-complete.

SECTION I. TERRESTRIAL.

Obs. The insects which compose this section are not
**Tribe I. Pentatomidae.**

Antennae composed of five joints. Rostrum with four distinct joints, the three first of nearly an equal length. Labrum very long, striated. Tarsi with three distinct joints, the first elongate. Head trigonate, immersed even to the eyes in the thorax.

**Family I. Scutellerida.**

Scutellum elongate, covering the elytra and the wings.

*Genus CCLXX.* Scutellera. Lam. Latr. Leach.

Tetra. Fabricius.

Scutellum covering the whole of the abdomen, longer than broad. Thorax very narrow in front. Antennae with the second joint shorter than the third.

*Sp. 1. Sexmaculata.* Red shining with silver; feet, antennae, middle of the thorax, six spots on the scutellum, breast, epigastrium, and margin of the abdomen, black.

*Inhabit* new Caledonia.

Cimex. Linn.

Scutellum longer than broad, not covering the sides of the abdomen. Thorax very narrow in front. Antennae with the second joint longer than the third.

*Sp. 1. Lineata.* Red, thorax with six black lines; scutellum with four black spots; marginal spots of the abdomen, and six lines of black punctures.

*Cimex lineatus.* Linn.

Tetra nigro-lineata. Fabricius.

*Scutellera nigro-lineata.* Latreille.

*Inhabit* the southern parts of Europe.

Tetra. F. Fabricius.

Cimex. Wolff.

Scutellum broader than long. Antennae with the second joint very short. Thorax with the anterior margin not much narrower than the hinder margin.

*Sp. 1. Globulus.* Orbiculate, somewhat triangular, broader behind, shining brassy-black, punctate; base of antennae, row of punctures on each side of the abdomen, and knees, red-yellowish; scutellum with an impressed arcuate line on each side of the base.

*Tetra globulus.* Fabricius.

*Cimex globulus.* Wolff. Icon. Sim. fasc. 1. p. 3. tab. 1. fig. 3.

*Inhabit* southern Europe.

**Family II. Pentatomida.**

Scutellum not covering the wings or elytra.

*Genus CCLXXIII.* Aelia. Fabricius.

Cimex. Linn. Wolff.

Pentatoma. Latreille.

Body ovate. Thorax with the anterior margin much narrower than the hinder. Head longer than broad.

*Sp. 1. Acuminata.* Pale-yellowish, longitudinally lined with fuscous, impressed, punctate; a fuscous band running down the middle of the back, divided by a whitish line; last joint of the antennae red.

*Cimex acuminatus.* Linn.

*Aelia acuminata.* Fabricius.

*Pentatoma acuminata.* Latreille.

*Inhabit* grassy places. It is rare in Britain.

Body ovate. Thorax with the anterior margin much narrower than the hinder. Head with nearly equal diameters.

*Sp. 1. Bidens.* Body griseous above; thorax with bidens a lengthened spine on each side behind.

*Cimex bidens.* Fabricius.

*Pentatoma bidens.* Latreille.

*Inhabit* Europe.

*Sp. 2. Prasinus.* Green above; hinder angles of the Prasinus thorax without spines.

*Cimex prasinus.* Fabricius.

*Pentatoma prasina.* Latreille.

*Inhabit* Europe.

*Sp. 1. Oleraceus.* Brassy dark green; sides of the Oleraceus head and thorax with a longitudinal line, on the latter red; outer margin of the elytra, a spot on each, with two spots and the apex of the scutellum red; thighs, (apex excepted,) and middle of the tibia yellowish.

*Inhabit* Europe.

**Tribe II. Coreida.**

Antennae composed of four joints. Rostrum with four distinct joints, the first three of nearly an equal length. Labrum very long, striated. Tarsi with three distinct joints, the first elongate. Head trigonate, immersed even to the eyes within the thorax.

Cimex. Linn. Geoffroy, &c.

Antennae inserted above a line drawn from the eyes to the base of the labrum; the last joint thick. Thorax with the anterior narrower than the posterior margin. Body ovate, the sides of the abdomen dilated. Head trigonate; neck not apparent.

*Sp. 1. Marginatus.* Red-fuscous, obscure; sides of Margue the abdomen elevated, acute; antennae with their internal base unidentate, the first and last joints blackish, the middle ones red; thighs beneath with a canal, and a few little teeth.

*Coreus marginatus.* Fabricius, Latreille.

*Cimex marginatus.* Linn.

*Inhabit* Europe. Is common on the dock.

*Genus CCLXVII.* Bernitius. Fabricius.

Nebris. Latreille.

*Antennae inserted above a line drawn from the eyes to the base of the labrum; gercinated about their middle; the first joint very long, the last thick. Body fill-
ENTOMOLOGY.

Cimex. Linn.

Tipulidæ.

Sp. 1. Tipularius. Reddish-gray; antennæ as long as the body, with the last joint fuscous; elytra acuminate, and produced; thorax with three elevated lines, which are parallel and longitudinal, two of these are marginal, the other dorsal; elytra striate nervous, impressed-punctate, spotted with fuscous.

Cimex tipularius. Linn.

Fabricius.

Nedes tipularius. Latreille.

Inhabits grassy places.

Antennæ filiform, inserted beneath a line drawn from the eyes to the base of the labrum. Body elongate-ovate. Head trigonate, neck not apparent.

Cimex apeters. Stewart.

Legus apeters. Fabricius.

Inhabits Europe.

Cimex. Linn.

Lycus. Wolff.

Head trigonate, neck not apparent. Antennæ setaceous; the second joint at the apex thick, the two last when combined, much shorter than the one before it.

Genus CCCLXIII. Mydous. Fabricius, Latreille.

Cimex. Linn.

Lycus. Wolff.

Antennæ setaceous, the second and following joints alike. Head trigonate. Neck not apparent.

Genus CCCLXXXI. Mydous. Latreille.

Head ovate, with a distinct neck. Antennæ slightly thicker towards their extremities.

Tipulidæ.

Mydous tipulidæ. Latreille.

Tribe III. Cimicidæ.

Rostrum with two or three distinct joints. Labrum very short, not projecting. Feet simple. Eyes not very large.

Family I. Cimicida.

Feet formed for walking on the earth, with distinct nails.

Genus CCCLXXII. Nabil. Latreille.

Reduvis. Wolff.

Body not linear. Antennæ inserted below the middle of the head. Rostrum, with the second joint almost as long as the third. Thorax not bilobed.

Body not linear. Antennæ inserted above a line drawn from the eyes to the base of the rostrum. Rostrum, with the middle joint evidently longer than the others. Thorax bilobate, abruptly elevated behind. Tibia alike, elongate, somewhat cylindrical.

Inhabits Europe, is often found in houses, and is said to destroy the common house bug Cimex leucarius.

Genus CCCLXXIV. Petalocephus. Leach.

Petalocephus. Palissot de Beauvois.

Reduvis. Lateille.

Body not linear. Rostrum, with the middle joint evidently longer than the others. Thorax abruptly elevated behind, bilobate. Anterior tibia dilated into an oval plate.

Inhabits Africa.

Genus CCCLXXV. Zelus. Fabricius, Latreille.

Zelus. Linneus, De Geer, &c.

Body linear. Anterior pair of feet like the others in form; four hinder ones very long, and filiform.

Genus CCCLXXVI. Phymata. Scopoli, Latreille.

Phymata. Fabricius.

Elongate, with the sides dilated into an angle. Anterior feet raptorial. Antennæ capitate, the last joint very large, elongate-ovate. Scutellum very large, unconnected with the thorax, covering nearly the whole of the abdomen.

Gerris vagebunda. Fabricius.

Genus CCCLXXVII. Cimex. Linn. Latr.

Cimex. Geoffroy.

Cimex lactularius. Linn. Fabr. Latr. &c.

Acantia lactularia. Fabricius.

Inhabits European houses, sucking the blood of man.

The common bug.

Genus CCCLXXVIII. Macrocephalus. Swederus.

Macrocephalus. Swedenu, Nov. Act. Stockh. 8. 1787. 3. tab. 8. Fig. 1.

Genus CCCLXXIX. Physymata. Latreille, Leach.

Physymata. Fabricius.

Acantia. Schellenberg, Wolfi.

Abdomen with the sides dilated into an angle. Anterior feet raptorial. Antennæ capitate, the last joint very large, elongate-ovate. Scutellum very large, unconnected with the thorax, covering nearly the whole of the abdomen.

Genus CCCLXXIX. Physymata. Latreille, Leach.

Physymata. Fabricius.

Syrtis. Swederus, Nov. Act. Stockh. 8. 1787. 3. tab. 8. Fig. 1.
ENTOMOLOGY.

The species of this genus are certainly but little known; they are either subject to great variation, or are very numerous.

Tribe IV. Acanthides.

Labrum prominent. Eyes very large. Feet formed for walking and jumping.

Tribe V. Belostomides.

Tarsi alike, all cylindrical, biarticulated, and furnished with nails. Body depressed.

Family I. Pselionidae.

Family II. Belostomidae.

Tribe VI. Nepides.

Anterior tarsi united with the tibia. Body depressed or linear.

Family I. Naucorida.

Anus without setae. Tarsi of the four posterior feet distinctly biarticulate. Antenna four-jointed.
ENTOMOLOGY.

**Family I. Nepida.**

Animous furnished with two sets. Tarsi of the four posterior feet one jointed. Antennae three jointed.

Nepa. Geoffroy.

Le Scorpion aquatique a corps ovale. Geoffroy.

Le Scorpion aquatique a corps allongé. Geoffroy.

Inhabits the ditches and ponds of Europe. This is very local in this country. It may occasionally be found near London in Copenhagen Fields, and in ponds near Hammersmith. It has likewise been taken near Halesworth in Suffolk.

**Family II. Notonectidae.**

Tarsi of anterior feet not united with the tibiae. Body depressed cylindrical, or cylindro-oval.

Nepa. De Geer.

Scutellum triangular, large. Four anterior feet with strong nails; the hinder pair elongate, ciliated, with very minute nails.

**Family III. Corixida.**

Tarsi of the four anterior feet one jointed, of the hinder pair two-jointed.

Corixa. Fabr. Schrank, Schellenberg.

Anterior pair of feet without nails; the other feet long, furnished with nails. Scutellum none.

ENTOMOLOGY.

CICADA. Linn. Geoffroy.
Membraecis. Olivier, Lamarck, Schrank.
Antennae inserted in the frontlet, the two first joints equal in length, the first rather thickest, the third ending in a long seta. Thorax on each side dilated into an auricle.

Genus CCCCV. Membraecis. Latr.
Centotus. Fabr.
Membraecis. Fabr.
Cicada. Linn.
Antennae inserted in the frontlet; the two first joints nearly equally long; the third elongate-conic. Thorax dilated behind.

Cicada cornuta. Linn.
Centotus cornutus. Fabr.
Membraecis cornuta. Latr.

FAMILY IV. Cicadida.
Antennae inserted between the eyes. Thorax transverse, hinder margin straight.
Genus CCCCVI. Iassus. Fabr.
Tettigonia. Latr. Olivier, Lamarck.
Front broad, not longer than broad, on each side above the insertion of the antennae produced into an angle.

Sp. 1. Lario.
Cicada lario. Panzer.
Iassus lario. Fabr.
Tettigonia lario. Oliv. Lamarck.
Inhabits Europe.
Tettigonia. Olivier, Lamarck.
Front elongate-quadrato, the apex truncate, convex, thickened.

Cicada viridis. Fabricius, Panzer.
Tettigonia viridis. Latreille.
Inhabits Europe.

TRIBE III. Psyllides.
Tarsi with two joints distinct. Antennae with ten or eleven joints, the last with two setae. Legs formed for leaping. Both sexes with wings.
Genus CCCCVIII. Psylla. Geoffroy, Olivier, Latreille.
Antennae filiform or slightly setaceous, as long as the body. Thorax with the anterior margin arcuate.

Sp. 1. Alni. Green-yellowish; anterior segment of Alni. the thorax, seuitellum, squama of the elytra and nerves green.
Chermes betulae alni. Linn.
Chermes alni. Fabricius.
Peplia alni. Latreille.
Inhabits the alder.
Genus CCCCVII. Livia. Latreille.
Diraphia. Illiger.
Antennae shorter than the thorax, the base much thickened even to the middle. Thorax with the anterior segment transverse, straight.

Inhabits Junce.

TRIBE V. Aphides.
Tarsi two-jointed; the first joint very short. Rostrum in both sexes. Antennae with six or seven or eight joints. Females generally apterous.
Tarsi with the last joint vesiculous. Antennae eight-jointed. Rostrum minute, horizontal, externally without joints. Head elongate quadrato.

**Genus CCCCX. Thrips.** Linn. Geoffroy, Latreille, Lamarck, Olivier.

Elytra and wings horizontal and linear.

**Phytopus.** Sp. 1. **Physapus.** Black, hairy; antennae, tibiae and tarsi pale; middle of the tibia pale brown; elytra and wings white.

**Thrips physapus.** Linn. Fabricius, Latreille.

**Family II. Aphids.**

Tarsi with the last joint with two nails. Antennae six or seven-jointed. Rostrum very distinct, nearly perpendicular, with three distinct joints. Head transverse.

Antennae setaceous or filiform, seven-jointed. Elytra larger than the wings, elongate-angulate. Abdomen towards the apex generally tuberculated or horned. Eyes entire.

The animals of this genus are very numerous, and are found on almost every plant. The French call them *Puceron*, the English *Plant-lice*. The species require examination. The females are generally apterous.

**Genus CCCCXII. Aleurodes.** Latr. Lamarck.

**Tinea.** Linnaeus.

**Chelidonii.** Sp. 1. **Chelidonii.** Body yellowish, or rosy powdery, white; eyes black; each elytra with a puncture and spot of black.

**Tribe VI. Aphides.**

Tarsi with one joint and one nail. Rostrum in the female. Wings in the male, but no elytra. Female apterous.

**Genus CCCCXIII. Dorthesia.** Bosc. Latr.

**Coccus.** Dorthes, Fabr. Oliv.

Antenna of the female eight-jointed. Abdomen of the males very setose behind.

**Characias.** Sp. 1. **Characias.**

Inhabits the *Euphorbium characias* of southern France.

Antennae of the female eleven-jointed. Abdomen of the males with two very long setae at the apex.

**Sp. 1. Caci.**

**Coccus caci.** Linn. De Geer, Fabr. Latr.

Inhabits fruit-trees.

This genus requires a minute investigation, which should be conducted by some one possessing a great share of patience, and having a very competent knowledge of entomology.

**Order X. Aptera.**

**Order Aptera.** Linn. Delam.

**Order Suctoria.** Latr.

**Characters of the Order.**

Body somewhat ovate, compressed, covered with a coriaceous skin, and composed of several segments. Trunk short, consisting of three leg-bearing joints. Head small, compressed, rounded above, and truncate before. Eyes minute, orbicular, lateral. Antennae lamelliform, small, ciliated with spinules, one-jointed at their base, inserted in two excavations behind the eyes. Palpi filiform (composed of four rounded joints), scarcely longer than the head, erect, generally resting on the rostrum. Legs strong, and formed for jumping, especially the hinder ones. Coxae and thighs large, compressed. Tarsi elongate, cylindrical, composed of five simple joints, the last articulation furnished with two long, acute, slender nails.

**Larva** without feet.

**Pupa** foliataceous.

**Genus CCCCXV. Pulex.** Olivier, of authors.

Sp. 1. **Irritans.** Body brumous, sometimes inclining to rust-colour.

The common bed-flea. Is found throughout Europe.

Notwithstanding the inconveniences attending this little insect, there is something pleasing in the appearance of the flea. Its motions are elegant, and all its postures indicate agility. The shell with which it is enveloped is in a state of perpetual cleanliness, while the muscular power which it is capable of exerting is so extraordinary, as to excite our wonder, at so much strength confined and concentrated within so small a space; this species being able to spring, on the most moderate computation, to the distance of at least 200 times its own length. It is remarkable, that Socrates was ridiculed for his pretended experiments on this subject, by Aristophanes. Arist. Clouds, act i. scene 2. This circumstance is alluded to in Butler’s *Hudibras*.

Sp. 2. **Penetran.** The chigger.

Inhabits the West Indies, penetrating the human skin, and depositing a parcel of eggs within a sac.

The pullice of birds and of mammals ought to be most carefully examined. There are a vast number of species which have been confounded with *P. irritans*.

**Order XI. Lepidoptera.**

**Characters of the Order.**

Wings four, covered with scales. Tongue spiral, filiform.

Linné divided this order into three genera, viz. *Papilio* (butterfly), *Sphinx* (hawk-moth), and *Phalaena* (moth), which were characterized by the form of their antennae; and these divisions form the three great sections of Latreille, as follow.

**Section I. Diurna.**

Wings four; all, or at least the superior ones, erect when the insect is at rest. Antennae with their points thicker or capitate; in a very few somewhat setaceous, with the extreme apex hooked.

The insects of this section, which constituted the Linnean genus *Papilio*, all fly by day. Caterpillars with sixteen feet. Chrysalis naked, and generally angulated.

**Tribe I. Papilionides.**

Hinder tibiae with levels only at their extremities. Antennae not ungualted or hooked at their extremities. Wings all elevated when at rest.

* We shall for the most part only introduce the indigenous genera, with a complete enumeration of the British species.
Family I. Papilionidae.

Caterpillar elongate, cylindrical. Chrysalis elongate, angular. Tars of Imago with distinct nails.

Antennae at their points, furnished with a conico-ovate or lengthened-ovate, somewhat arcuate, club. Palpi very short, pressed close to the face, scarcely reaching the clypeus; the two first joints of equal length; the third minute, and nearly obsolete. Feet in both sexes alike, all being formed for walking, and furnished with distinct but simple claws. Anterior wings generally somewhat falcate; hinder ones often tailed; the internal margin excised or folded to admit of free play for the abdomen.

The caterpillar is tentaculated, fleshy, and fuscate. The chrysalis is angulated, with two processes before; it fastens itself by a transverse thread.

The species of this genus, which constitutes the most beautiful part of the creation, are found chiefly in the warmer regions, very few occurring in the more temperate parts of the world. Their flight is extremely rapid.

Sp. 1. Machaon. Black and yellow; hinder wings tailed; edges of the wings black, with yellow crescents; the tips of the hinder wings with a red spot at their inferior tips.

Papilio Machaon. Linn. Fabr.

Inhabits Europe; the larva in the fennel.

In England it is called the Swallow-tailed Butterfly, and is very local. It is the most superb of all the British species of this family. The caterpillar is green, banded with black, marked by a row of red spots. It changes into the chrysalis state in July; and the fly is found in August. Two broods are said to be found; the first in May, having lain in the chrysalis or pupa state all the winter.

Papilio podalirius of Linne, which belongs to this genus, has been introduced into the British Fauna, on very dubious authority.

Genus CCCCXVII. Doritis. Fabricius.

Parnassius. Latreille.

Pieris. Schrank.

Feet all alike in both sexes. Ungues or claws simple. Palpi rising above the clypeus, very prominent, cylindrical-ovate with three very distinct joints. Antenna with a thickened, somewhat ovate straight head. Hinder wings not tailed; the internal margin excised, to admit of free play for the abdomen.

The chrysalis smooth, somewhat folliculate.

Sp. 1. Apollo. Wings white, rounded, spotted with black; the lower pair marked with annular red spots.

Papilio Apollo. Gmelin.

Parnassius Apollo. Linn. Fabr.

Doritis Apollo. Latreille.

Inhabits Germany and France.

Larva black, spotted with red. Chrysalis brown, powdered with violet.

This elegant insect, which has been confounded by some authors with Doritis Nemorum, and Phoebus, is mentioned here in order to inform the reader, that it has no right or title whatever to a place in the British Fauna, although it has been described as such by Mr Harworth, and has been figured by Mr Donovan on the most vague and unsatisfactory authority.

Genus CCCCXVIII. Pontia. Fabr.

Pieris. Schrank.

Antennae elongate, with an abrupt, obconic, compressed head. Palpi slender, somewhat cylindrical; the last joint as long as the preceding. Wings not very narrow, row, or much lengthened; hinder ones grooved to admit the abdomen, but not tailed. Feet alike in both sexes; claws unidentate or bifid.

Chrysalis angulated, fastened by a transverse thread.

* Anterior wings somewhat trigonate; hinder ones somewhat orbiculate.

Papilio cretagi. Linn.

Pieris cretagi. Schrank. Latr.

Pontia cretagi. Fabr.

Inhabits Europe. In England, it is found near London, where it is called Black-veined white.

Sp. 2. Brassicae, (large cabbage-butterfly).

Papilio brassicae. Linn.

Pontia brassicae. Fabr.

Pieris brassicae. Latr.

Inhabits Europe everywhere. The larva feeds on the cabbage.

Sp. 3. Rapes (small cabbage-butterfly).

Papilio r apex. Linn.

Pieris r apex. Fabr.

Inhabit Europe on cabbages.

Sp. 4. Napi, (green-veined white butterfly).

Papilio napi. Linn.

Pontia napi. Fabr.

Pieris napi. Latr.

Inhabits Europe everywhere.

Sp. 5. Cardamines, (orange-tipt butterfly).

Papilio cardamines. Linn.

Pontia cardamines. Fabr.

Pieris cardamines. Latr.

Inhabits Europe. The larva feeds on the Cardamine pratensis.

Papilio daphidice, Linn. Fabr.; Pontia daphidice of Latreille, has been introduced into the British catalogue, but on very slender authority.

* * Wings somewhat oval.

Papilio sinapis. Gmelin.

Pieris sinapis. Latr.

Genus CCCCXIX. Colias. Fabr. Latr.

Pieris. Schrank.

Antennae short, gradually thickening into an obconic head. Palpi much compressed; the last joint very short. Feet alike in both sexes, all with bifid, or unidentate nails. Wings anterior, somewhat trigonate; hinder rounded, with a groove to receive the abdomen.

Chrysalis angulated, fastened by a transverse thread.

Papilio Hyale of authors.

Pieris Hyale. Schrank.

Colias Hyale. Fabr. Latr.

Inhabits Europe. Occurs in England once in three years, in great plenty, in every part of the country. There is a paler colored variety of each sex, which have been considered as distinct species.

Genus CCCCXX. Gonepteryx. Leach.

Colias. Fabr. Latr.

Pieris. Schrank.

Antennae short, gradually thickening into an obconic head. Palpi short, much compressed; the last joint very short. Feet alike in both sexes, all with a bifid or unidentate nail. Wings angulated, large, the hinder one grooved to receive the abdomen.
Chrysalis angulated, with a thread round its middle.
Sp. 1. Rhauni. Wing of the male yellow, of the female whitish; with a fulvous spot on each.
Papilio rhamni. Linn.
Colias rhamni. Fabr. Latr.
Pieris rhamni. Schrank.
Gonepteryx rhamni. Lec.ens.
Inhabits Europe in the spring and autumn. Flight slow.

Antennae terminated with a short club. Palpi divaricating abruptly, terminated with a minute, slender, acicular, very short joint; the second joint broad, hairy. Hinder wings orbicular. Anterior feet very short in both sexes. Tarsi with double nails. Chrysalis suspended by the tail. Caterpillars spiny.

Inhabits the borders of woods in Germany, England, and France.

Genus CCCCXXII. Melita. Fabr.
Antennae terminated by a short club. Palpi very hairy, divaricating, with the last joint acicular, half the length of the preceding joint. Hinder wings orbicular. Anterior feet very short in both sexes. Tarsi with double nails. Caterpillars pubescent, with fleshy tubercles. Chrysalis suspended by the tail.

Papilio Euphydryas. Linn.
Argynnis Euphydryas. Latr.
Melita Euphydryas. Fabr.
Inhabits waste grounds and heaths.

Melita Silene. Fabr.
Inhabits the same places with the preceding species.

Sp. 3. Cinzia. (Glanville).
Papilio Cinzia. Gmelin.
Melita Cinzia. Fabr.
Argynnis Cinzia. Latr.
Inhabits Europe. Rare in Britain.

Melita Artemis. Fabr.
Inhabits Europe. Is common near Norwich in Norfolk.

Sp. 5. Dicytyna. (Heath).
Papilio Dicytyna. Gmelin.
Melita Dicytyna. Fabr.
Inhabits heaths and marshes. Papilio cec of Haworth seems to be a variety.

Papilio Lucina. Gmelin.
Melita Lucina. Fabr.
Inhabits borders of woods and hedges.

Genus CCCCXXIII. Vanessa. Fabricius, Latreille.
Antennae terminated with an abrupt short club. Palpi contiguous and terminated gradually in a point; the two combined bearing some resemblance to a rostrum. Anterior pair of feet in both sexes short and very hairy. Tarsi with double nails. Chrysalis suspended by its tail. Caterpillars spiny.

Sp. 1. Atlas. (Red admirable.)
Papilio Atlas. Linn.
Inhabits Europe. The larva on nettles.
Sp. 2. Carcharias. (Painted lady.)
Papilio carcharias. Linn.
Vanessa carcharias. Fabricius, Latreille.

Sp. 3. Antiopa. (Camberwell beauty.)
Papilio Antiopa. Linn.
Vanessa Antiopa. Latreille.
Inhabits Europe. The English variety has invariably a white margin to the wings.

Sp. 4. Io. (Peacock.)
Papilio Io. Linn.
Vanessa Io. Fabricius, Latreille.
Inhabits the nettle.

Sp. 5. Polychloros. (Large tortoise-shell.)
Papilio Polychloros. Linn.
Vanessa Polychloros. Fabricius.
Inhabits Europe. The larva on the elm.

Sp. 6. Comma. (Small tortoise-shell.)
Papilio urticae. Linn.
Vanessa urticae. Latreille, Fabricius.
Inhabits Europe.

Sp. 7. C-album. (Comma.)
Papilio c-album. Linn.
Vanessa c-album. Fabricius.

Genus CCCCXXIV. Hipparchia. Fabricius, Leech.

Satyra. Latreille.

Antennae with a slender somewhat fusiform or somewhat trigonate orbicular club. Palpi meeting above the tongue, with the second joint very much compressed, and very much longer than the first. Anterior pair of legs shorter than the rest, and often very hairy; feet of the other legs with double nails. Hinder wings somewhat orbicular or orbiculate-triangulate, with the internal margin excavated to receive the abdomen; the middle cell closed behind, from which part the nerves radiate; the other margin entire, or with acute or obtuse indentations. Caterpillar downy, with a globular head somewhat compressed in front; the abdomen bimaculate behind. Chrysalis angulated, with the front bimaculate suspended by the tail. Leach's Zoolog. Miscel. vol. i. p. 27.

Sp. 1. Galatea. (Marbled.)
Papilio Galatea. Linn. Gmelin.
Hipparchia Galatea. Fabricius.
Satyra Galatea. Latreille.
Inhabits Europe in fields.

Sp. 2. Hyperanthus. (Eyed.)
Papilio Hyperanthus. Linn.
Hipparchia Hyperanthus. Fabricius.
Satyra Hyperanthus. Latreille.
Inhabits Europe in fields.

Sp. 3. Pamphilus. (Heath.)
Papilio Pamphilus. Linn. Gmelin.
Hipparchia Pamphilus. Fabricius.
Satyra Pamphilus. Latreille.

Pamphilus.
Family II. Lycaenida.

Larva oval, depressed. Pupa or chrysalis short, con-tracted, obtuse at both extremities. Tarsi with very small nails.

Genus CCCCXXVII. THECLA. Fabr.

POLYOMMATUS. Latr.

Feet in both sexes all alike; nails scarcely produced beyond the pulvilli, which are large. Antenna generally clubbed; the club elongate, cylindrical oval. Hinder wings tailed.

Sp. 1. Betula. (Brown hair streak.)
Papilio betula. Gmelin.
Thecla betula. Fabr.
Polyommatus betula. Latr.

Inhabits Europe, frequenting the borders of woods.

Sp. 2. Pruni. (Black hair-streak.)
Papilio pruni. Hübner.
Thecla pruni. Fabr.

Polyommatus pruni. Latr.

Inhabits borders of woods.

Sp. 3. Quercus. (Purple hair-streak.)
Papilio quercus. Gmelin.
Thecla quercus. Fabr.

Inhabits oak woods, flying on the highest branches of the trees.

Genus CCCCXXVIII. LYCÆNA. Fabr.

POLYOMMATUS. Latr.

Legs alike in both sexes; nails projecting beyond the pulvilli, which are small. Antenna with an abrupt club, somewhat ovate, or somewhat oval.

* Hinder wings more or less tailed.

Sp. 1. Dispar. (Large copper.)
Papilio dispar. Haworth.

Papilio Hypophloeus. Donovan.

Inhabits the fens of Cambridgeshire, and has been observed near Aberdeen in Scotland.

Sp. 2. Chryseis. (Purple-edged copper.)
Lycaena Chryseis. Fabr.

Inhabits Europe. In Britain it is extremely rare.

Sp. 3. Virgaea. (Scarce copper.)
Lycaena virgaea. Fabr.

Inhabits Europe. Very local in Britain. It is found in some parts of Huntingdonshire.

Sp. 4. Phlaeas. (Small copper.)
Lycaena Phlaeas. Fabr.

Polyommatus Phlaeas. Latr.

Inhabits Europe; much attached to syngenesious plants.

Sp. 5. Rubi. (Green underside.)
Papilio rubi. Gmelin.

Lycaena rubi. Fabr.

Polyommatus rubi. Latr.

Inhabits Europe.

* * Hinder wings with the posterior margin entire.

Sp. 6. Corydon. (Chalk-hill blue.)
Papilio Corydon. Linn. Gmelin.

Lycaena Corydon. Fabr.

Polyommatus Corydon. Latr.

Inhabits chalky districts.

Sp. 7. Adonis. (Cliffen blue.)
Papilio Adonis. Linn. Gmelin.

Lycaena Adonis. Fabr.

Inhabits chalky districts.

Sp. 8. Dorylas. (Common blue.)
Papilio Dorylas. Gmelin?
Papilio Icarus. Lewin.

Inhabits Europe everywhere.

Sp. 9. Argus. (Studded blue.)
ENTOMOLOGY.

Metamorphosis.

Papilia Argus. Gmelin.
Lycaen Argus. Fabr.
Polyommatus Argus. Latr.
Inhabits fields and meadows.

Idas.

Sp. 10. Idas. (Black-spot brown).
Papilia Idas. Gmelin.
Lycaen Idas. Fabr.
Inhabits Europe.

Artaxerxes.

Sp. 11. Artaxerxes. (White-spot brown).
Papilia Artaxerxes. Gmelin, Stewart.
Lycaena Artaxerxes. Fabr.
Inhabits Arthur's Seat, and the base of Kirk-hill, one of the Pentland range, near Edinburgh, in great plenty.

Alsus.

Papilia Alsus. Gmelin.
Lycaena Alsus. Fabr.
Polyommatus Alsus. Latr.
Inhabits Europe.

Argiolus.

Papilia Argiolus. Gmelin.
Inhabits meadows.

Cymon.

Papilia Cymon. Gmelin, Lewin.
Inhabits Europe. In Britain it is very local. It is found near Sherborne in Dorset, in great abundance.

TRIBE II. HESPERIDES.

Hinder tibiae with two pair of heels or spurs, one pair at the middle, the other at the usual place. Antennae hooked at their extremities. Hinder wings elevated when the insect is at rest.

FAMILY I. Uranida.

Antennae filiform, their points narrower and bent.
Palpi long, slender.

Genus CCCCXXIX. Urania. Fabr. Latr.

Papilia. Linn. Cramer.
Palpi with the second joint much compressed, the third slender, somewhat cylindrical, almost naked.

Dinóz.

Sp. 1. Leilus.
Papilia Leilus. Linn.
Urania Leilus. Fabr.

FAMILY II. Hesperida.

Antennae distinctly terminated with a club. Palpi short, thick, and squamous in front.

Latr. Walek.
Papilia. Linn.
Palpi with the third joint cylindrical, or cylindrical-conic.

* Antennae ending in an abrupt, very acute hook.

Comuna.

Papilia Comma. Gmelin.
Hesperia Comma. Fabr. Latr.
Inhabits Europe. In England, near Lewes, in Sussex.

Sylvana.

Papilia Sylvana. Gmelin.
Hesperia Sylvana. Fabr. Latr.
Inhabits the borders of woods.

* * Antennae with their points arcuate.

Tagetes.

Sp. 3. Tagetes. (Dingy skipper).
Papilia Tagetes. Gmelin.
Hesperia Tagetes. Fabr. Latr.
Inhabits Europe, on dry heaths and banks.

Malva.

Sp. 4. Malva. (Mallow skipper).

Papilia malva. Gmelin.
Hesperia malva. Fabr. Latr.
Inhabits dry banks.

* * Antennae with straight points.

Sp. 5. Linea. (Small skipper).
Hesperia linea. Fabr. Latr.
Papilia linea. Gmelin.
Inhabits the margins of woods.

Sp. 6. Paniscus. (Scarce skipper).
Papilia Paniscus. Gmelin.
Inhabits meadows. Very rare in Britain, excepting in some parts of Bedfordshire, where it is common.

Sect. II. CREPUSCULARIA.

Wings horizontal in repose. Antennae prismatic or fusiform.

The insects of this tribe constitute the Linnean genus Sphinx, which has been divided by Fabricius, Latrellle, Scopoli, and Hoffmannsegg, into a number of genera.

TRIBE I. SPHINXES.

Palpi short, covered with very short, close scales; the last joint tubercuiform and very short.

Genus CCCCXXXI. Laothoe. Fabr.

Sphinx. Linn.

Spectrum. Scopoli.

Smerinthus. Latr.

Antennae somewhat prismatic, serrated towards the middle, gradually thicker. Tongue very short. Anterior wings angulated. Palpi contiguous.

Sphinx ocellata. Linn.
Laothoe ocellata. Fabr.
Spectrum ocellatum. Scopoli.
Smerinthus ocellatus. Latr.
Inhabits Europe. The larva in the willow and poplar.

Sp. 2. Tiliae. (Lime hawk-moth).
Sphinx tiliar. Linn. Gmelin.
Laothoe tiliar. Fabr.
Spectrum tiliar. Scopoli.
Smerinthus tiliar. Latreille.
Inhabits the lime in the caterpillar state.

Sp. 3. Populi. (Poplar hawk-moth).
Sphinx populi. Linn. Gmelin.
Laothoe populi. Fabr.
Spectrum populi. Scopoli.
Smerinthus populi. Latr.
Inhabits Europe. The larva on poplars and willows.

Spectrum. Scopoli.

Palpi contiguous above the tongue. Tongue long, very distinct, convoluted. Antennae prismatic, thicker towards their middle, in the males slightly ciliated.

Abdomen with the anus not bearded.

Sp. 1. Porcellus. (Small elephant hawk-moth.)
Sphinx porcellus. Gmelin, Fabricius, Latreille.
Inhabits Europe. Is rare in Britain.

Sp. 2. Alpensperg. (Elephant hawk-moth.)
Sphinx Alpensperg. Linn. Latreille, Fabricius, Gmelin.
Inhabits Europe.

Sp. 3. Lineata. (Silver line hawk-moth.)
Sphinx lineata. Linn.
Inhabits Europe. Obs. Sphinx Lineata of Donovan.
ENTOMOLOGY.

Palpi long, separate, covered with long scales, or correded hair.

**Tribe Zygænidae.**

Palpi short.

Sp. 1. Statice. (Forrester.)
*Sphinx* statice. Linn.
*Zygæna statice.* Rossi, Panzer.
*Procris statice.* Fabricius, Latreille.
*Procris no 1.* Leach.

Inhabits the margins of woods in meadows.

**Section III. Nocturna.**

Wings horizontal in repose. Antenna setaceous, gradually narrowing towards their extremities.

**Tribe L. Bombycides.**

**Family L. Cossida.**

Antennae with a single series of cilia. Wings elongate.

*Obs.* The larve of this family generally live on the solid wood of trees, which they perforate in every direction. Sides of the chrysalis denticulated.

**Genus CCCCXXXVII. Hepialus.** Fabr. Latt.

*Phalaena* (Noctua.) Linn.

Antenna moniliform, shorter than the thorax. Pal-
pi very small, and very hairy. Wings elliptic, equal, long.

Hemul. Sp. 1. *Humuli.* (Giant-swift.)
Noctua humuli. Linn.
Hepialus humuli. Fabr. Latt.
Inhabits fields.

Mapa. Sp. 2. *Mapa.* (Map-wing swift.)
Phalaena *mappa.* Donovan.
Inhabits Britain. Has been taken near Dunstar castle, in Somerset, by Mr G. Sowerby. It may be synonymous with *Bombus velleta* of Hübn.

Hectus. Sp. 3. *Hectus.* (Golden swift.)
Phalaena *nocta* hector. Gmelin.
Hepialus hector. Fabr. Latt.
Inhabits Europe.

Obs. We have in Britain several other species, but their characters are evanescent, and their names have never been determined with accuracy.

Genus CCCCCXXXVIII. Cossus. Fabricius, Latt.

*Cossus* Bombyx. Linn.
Antenne as long as the thorax, setaceous, furnished with a single series of short transverse obtuse teeth. Palpi very distinct, thick, cylindrical, and squamous. Anterior wings larger than the posterior.

Ligntiperda. Sp. 1. *Ligntiperda.* (Coast moth.)
Phalaena (Bombus) *Cossus.* Linn.
*Cossus ligntiperda.* Fabricius, Latt.
Inhabits Europe. The larva feeds on the internal parts of the willow and ash. The celebrated Lyonnert has immortalized himself by his laborious work on the anatomy of the larva, and perfect insect. The caterpillar diffuses a scent, by which its residence may frequently be made known to those passing such trees as are much infested by it. It remains three years in this state, when it spins a strong web, intermixed with particles of wood, and changes into the chrysalis, which it does in the month of May, and in June the perfect insect starts into existence.

Genus CCCCCXXXIX. Zeuzera. Latt.

*Bombyx.* Hübn.
Hepialus. Schrank.
*Cossus.* Fabr. Latt.

Antenne setaceous, (in the male pectinated to the middle).

*Cossus aevulci.* Fabricius.
*Bombyx aevulci.* Hulper.
Zeuzera aevulci. Latt.
Phalaena aevulci. Linn.
Inhabits Europe. In England it is rather rare, but may be found in St James's Park, in July, if industriously sought after.

Family II. Bombycidae.

Antenne of the males with a double series of pectinations.

Obs. The larva of this family live on the leaves of trees. Sides of the chrysalis not serrated or denticulated.

Genus CCCCCXL. Saturnia. Schrank.
*Cossus.* (Attacus.) Linn.
*Bombyx.* Fabricius, Hulper, Latt.

Wings horizontal. Antenna with the second joint (in the male) hidended. Caterpillar naked, elongate, with the anal feet distinct, and resembling the middle ones.

Favonia. Sp. 1. *Favonia minor.* (Emperor moth.)

Phalaena *attacus* pagonia minor. Linn.
*Bombyx pagonia minor.* Fabr. Latt.

Inhabits Europe.

Genus CCCCCXL. *Lasiocampa.* Schrank.

*Bombyx.* Fabricius, Latt.

Superior wings deflected; inferior ones reversed. Antenne of the male very much pectinated. Palpi not produced into a rostrum. Caterpillar naked, elongate, with the anal feet distinct, and resembling the middle ones.

Sp. 1. *Quercus.* (The egger moth.)
Phalaena bombyx *quercus.* Linn.
*Bombyx quercus.* Fabr. Latt.
Inhabits Europe. The larva feeds on the bramble.

The four last are distinguished by their palpi, being more hairy than the rest, and may be considered as forming a subdivision.

Superior wings deflected, inferior ones reversed. Antenne of the male very much pectinated. Palpi produced into a rostrum. Caterpillar naked, with the anal feet like the middle ones distinct.

Sp. 1. *Quercifolia.* (Lappet moth.)
Phalaena bombyx *quercifolia.* Linn.
*Bombyx quercifolia.* Fabr. Latt.
Inhabits Europe.

Obs. The following indigenous *Bombyxes* of Fabricius belong to this genus, viz. 2. *Potatoria.* 3. *Pini.*

Genus CCCCCXIII. Laria. Schrank.

*Cossus.* (Bombus.) Linn.
*Bombyx.* Fabricius, Latt.

Wings deflected, the under ones entirely covered by the upper ones. Antenne of the male much pectinated, or much ciliated. Caterpillar naked; the hinder feet distinct like the middle ones.

Sp. 1. *Dispar.* (Gipsy moth.)
Phalaena dispar. Linn.
*Bombyx dispar.* Fabricius.
Inhabits Europe.

Genus CCCCCXIV. Cerura. Schrank.

*Bombyx.* Fabricius, Latt.

*Cerura.* (Bombus.) Linn.

Phalaena. (Bombus.) Linn.

Inhabits Europe. The larva feeds in willows and poplars.

Sp. 1. *Vinula.* (Puss moth.)
Phalaena bombyx *vinula.* Linn.
*Bombyx vinula.* Fabricius, Latt.
*Cerura vinula.* Schrank.

Inhabits Europe. The larva feeds in willows and poplars.

Sp. 2. *Furcula.* (Kitten moth.)
*Bombyx furcula.* Latt.
Inhabits Europe; not common in Britain.
Tribe II. Arctides.

Noctua-Bombyctae. Latreille.
Palpi two. Antennae pectinated, or ciliated. Tongue visible, but often short, and somewhat membranaceous. Wings trigonate, deflexed, undivided. Caterpillar with sixteen feet.

Genus CCCXLV. Arctia. Schrank, Latreille.
Bombyx. Fabricius.
Palpi with long scales. Antennae of the males (at least) with a double series of pectinations. Tongue often short, composed of two separate filaments.

* Antennae pectinated.

** Antennae ciliated.

Phaorhest. Sp. 3. Phaorhest. (brown tail moth). Bombyx phaorhest. Haworth. Bombyx chrysaorica. Hübner. Inhabits Europe. This is the species whose larvae commit such destruction amongst white thorn hedges, as mentioned in our history of entomological dissertations.

Genus CCCXLVI. Callimorpha. Latreille.
Bombyx. Fabricius.
Lotodia. Fabricius. Palpi with short, not pectinated scales. Antennae simple, or slightly ciliated. Tongue long, the two filaments conjoined.

Tribe III. Tineides.
Antennæ setaceous, simple. Tongue distinct. Palpi two, cylindrical. Wings long, oblong, somewhat elliptic, incumbent or convoluted, inferior ones much folded, all undivided.

Family I. Tineida.
Antennæ distant from each other. Eyes separate, divided by a frontlet.

Division I.
Tongue distinct, elongate. Front not very hairy.
Genus CCCXVII. Lithosia. Fabr. Latr.
Wings horizontal. Palpi shorter than the head, last joint cylindrical, distinctly shorter than the second. Back much flattened. Antennæ simple, or but slightly ciliated.

Genus CCCXLVIII. Yponomeuta. Latreille.
Wings rolled, or convoluted. Palpi as long as the head, the third joint oblique, as long or longer than the one before it. Antennæ simple.

Genus CCCXLIX. Nemapogon. Schrank.

Wings broadly fringed, lying on the back. Palpi twice as long or more than the body; the second joint longer than the head; the last joint almost naked, recurved beyond the head.

Obs. To this genus Tinea, 1. Linneus; 2. Flavella; 3. Roseella, and their congeners, belong.

Division II.
Tongue not distinct, very short. Front very hairy.
Genus CCCXL. Euplocamus. Latreille.
Palpi two; the second joint with numerous elongated scales, the third joint naked and ascending. Antennæ much pectinated.

Phalana (Tinea). Linneus.
Palpi four, distinct, upper ones small, inflexed. Antennæ simple, or slightly ciliated.

Obs. All the cloth moths, of which there are several species, belong to this genus.

Family II. Nemophorida.
Antennæ inserted very near to each other. Eyes nearly meeting behind.

Genus CCCXLI. Nemophora. Hoffmannsegg.

Obs. All the long-horned Japan moths, as they are called by English collectors, belong to this genus.

Tribe IV. Noctuides.
Antennæ setaceous; in the males sometimes pectinated or ciliated. Tongue distinct. Palpi much compressed. Wings horizontal or incumbent; not divided.

Thorax thick, often crested.
Family I. Erebida.

Palpi with the last joint as long or longer than the preceding.

Genus CCCCLVII. Entomaria. Linneus.

Noctua. Fabricius.

Wings expanded.

Noctua odorata. Fabricius, Latreille.

Family II. Noctuidae.

Palpi with the last joint much shorter than the preceding, squamous.

Bombyx. Fabricius, Hübner.

Phalana (Bombyx). Linneus.

Phalana (Noctua). Linneus.

Fabricius, Hübner.

Pachyta. Schrank.

Pucellia. Schrank.

Obs. The genus Noctua requires a minute investigation.

It contains several very natural genera, as exhibited in the following divisions:

1. Caterpillar with sixteen feet.

* Caterpillars half-loopers, their anterior feet membranaceous, evidently shorter than the others.

Wings horizontal.

Frazini.

Noctua fraxini. Fabricius, Latreille.

Sp. 2. Sponus, (crimson underwing).

Noctua spona. Fabricius, Latreille.

** Caterpillars with membranaceous feet of conformable size.

1. Wings horizontal.

Sp. 1. Fimbris. (Broad bordered yellow underwing moth).

Noctua fimbris. Fabricius.

2. Wings deflexed.

b. Sp. 1. Liguistei. (Coronet); 2. Pisii. (Broom moth), &c.

B. Caterpillar with fourteen feet.

Sp. 1. Chrysitis. (Barnished brass moth); 2. Festucce. (Gold spot moth), &c.

 Tribe V. Phalanaeides.

Antennae approximating at their base; those of the male often pectinated or ciliated. Clypeus scarcely prominent. Feet slender, rarely hairy. Palpi two.

Wings undivided.

Family I. Phalaenida.

Larva with twelve feet.

Genus CCCCLV. Phalana. Linneus, Fabricius, Latreille, Leach.

Geometra. Haworth, Hübner.

Antennae of the male pectinated.

Sp. 1. Margaritaria. (Large emerald moth), &c.

Family II. Geometrina.

Larva with ten feet.

Genus CCCCLVI. Biston. Leach.

Phalana. Linneus, Fabricius, Latreille.

Geometra. Haworth, Hübner.

Antennae of the male much pectinated. Body thick.

Palpi very hairy.

Phalana. Fabricius, Latreille, Linneus.

Antennae of the male pectinated. Body slender. Palpi but little or not at all hairy. Wings horizontally extended, hinder margin very angular.

Genus CCCCLVIII. Ourapteryx. Leach.

Phalana. Latreille, Fabricius, Linneus.

Antennae somewhat ciliated. Body slender. Palpi but little hairy. Wings horizontally extended, inferior ones prolonged, truncate, and terminated by a tail.

Inhabits Europe.

Genus CCCCLX. Abaxias. Leach.

Antennae simple, not ciliated. Body slender. Palpi scarcely hirsute. Wings extended horizontally, not angulated or indented.

Phalana piniaria. Fabricius, Linneus, Latreille.

Inhabits pine woods.

Genus CCCCLXI. Hipparchius. Leach.

Phalana. Fabricius, Linneus, Latreille.

Geometra. Hübner, Haworth.

Family III. Herminiaida.

Caterpillars with fourteen feet, the anal ones distinct, the first pair of membranaceous ones wanting.

Genus CCCCLXII. Herminia. Linneus.

Phalana (Pyhalis). Linneus.

Chambus. Fabricius, Bosc.

Pyralis. Hübner.

Wings triangulate, nearly horizontal, anterior margin of the upper wings straight. Palpi two recurved, compressed, often very large. Antennae ciliated.

Family IV. Platypterycidae.

Caterpillar with fourteen feet, anal ones wanting, the first pair of membranaceous ones distinct.

Genus CCCCLXIII. Platypteryx. Laspeyres, Latreille.

Phalana. Fabricius.

ENTOMOLOGY.

135

Obs. The two last species have their anterior wings dentate.

Genus CCCCLXIV. Ciliis. Leach.

Bombyx. Fabricius.

Platypteryx. Latreille.

Bombyx compressus. Fabricius.

Ciliis compressa. Leach.

Family V. Tortricida.

Caterpillars with sixteen feet. Wings, with the body forming a broad short triangle, dilated on side anteriorly.

Genus CCCCLXV. Tortrix. Hubner.

Phalaena (Tortrix). Linnaeus.

Pyralis. Latreille, Fabricius.

Palpi with the second joint distinctly longer than the third, and more squamous; third joint short, truncate or obtuse, not recurved over the head.

Fagana.

Tortrix. Hubner.

Pyralis. Latreille.

Palpi short, rising, the last joint not recurved over the head; with the second and third joints nearly equally long and equally squamous. Inferior wings not completely covered by the upper ones.

Dactana.

Pyralis dactana. Latreille.

Simaea dactana. Leach.

Inhabits Europe.

Nola.

Genus CCCCLXVII. Nola. Leach.

Pyralis. Hubner, Latreille.

Palpi short, porrect; last joint not recurved over the head; the second and third joints nearly equally long and equally squamous. Under wings completely covered by the upper ones.

Pallialasia.

Nola pallialasia. Leach.

Inhabits Europe.

Tribe VI. Pyralides.

Palpi four. Larva (as far as has been ascertained) with sixteen feet.

Family I. Pyralida.

Superior wings forming with the body a nearly horizontal depressed triangle.

Genus CCCCLXVIII. Botys. Latr.

Phalaena (Pyralis). Linnaeus.

Pyralis. Hubner, Schrank, Scopoli.

Nymphila. Schrank.

Scopula. Schrank.

Pyrausta. Schrank.

Crambus. Fabricius.

Tongue distinct, conspicuous. Palpi exserted.

4. Lemnata, &c.

Genus CCCCLXIX. Pyralis. Hubner, Schrank, Schiffermüller.

Phalaena (Pyralis). Linnaeus.

Crambus. Fabricius.

Aglossa. Latreille.

Tongue none. Inferior palpi largest, the second joint very squamous, the squamae so formed in bundles.

Phalaena pyralis. pinguiiialis. Linnaeus.

Crambus pinguiiialis. Fabricius.

Aglossa pinguiiialis. Latreille.

Inhabits Europe.

Family II. Tinctida.

Superior wings very long, enveloping the sides of the body.

Genus CCCCLX. Galleria. Fabricius, Linn.

Phalaena (Tinea). Linnaeus.

Tongue very short. Palpi short: inferior palpi largest, with short scales; upper ones concealed by the scales of the clypeus. Wings narrow, covering and pressing against the sides of the body.

Galleria alvearia. Fabricius, Linn.

Genus CCCCLXX. Crambus. Fabr. Linn.

Phalaena (Tinea). Linnaeus.

Tinea. Geoffroy.

Wings narrow, convoluted round the body. Palpi exserted, inferior ones largest. Head with short closely applied scales. Tongue distinct.

Pineti.

Color.

Alucita. Latreille.

Phalaena (Tinea). Linnaeus.

Ypsilonus. Fabricius.

Wings narrow abruptly deflexed, behind and above ascending. Inferior palpi with the second joint covered with numerous fasciculi of scales; the last erect, conic, naked. Head with a bifid crest in front.

Nemorum.

Tribe VII. Alucitidae.

Pterophorites. Latreille.

Wings divided, or formed of feathers united at their base.

Linn.

Alucita. Hubner, Schrank, Scopoli.

Phalaena (Alucita). Linnaeus.

Alucita. Hubner, Schrank, Scopoli.

Phalaena (Alucita). Linnaeus.

Ornithodes. Latreille.

Palpi produced much longer than the head; the second joint very squamous; the last joint naked, erect.

Pupa folliculate.

Pterophorus hexadactyla. Fabricius.

Phalaena alucita. hexadactyla. Linnaeus.

Alucita hexadactyla. Hubner.

Inhabits Europe, often entering houses.

Order XII. Trichoptera.

Order TrichoPTERA. Kirby.

Order NeuroPTERA. Linnaeus, Cuvier, Linn. T. Lam.
Characters of the Order.

Wings much deflexed, with strong nervures, hispid or hairy, the lower wings plicate. Antennæ inserted between the eyes, often very long, composed of an infinity of joints. Feet elongate, spinulose. Tarsi elongate, five jointed; the last joint with two small nails.

Larva elongate, agile, somewhat cylindrical, composed of twelve joints, the three first harder than the rest, and each bearing a pair of feet; the last segment with two hooked processes. It inhabits tubes constructed of sand, bits of wood, stone, or grass, glued together by a cement impenetrable to water.

Papa somewhat resembling the perfect insect, shut up in the tube it lived in whilst a larva, but having the power of motion prior to its emerging from the water (in which it resides), for the purpose of changing into the fly-state.

Obs. This genus Dr Leach has divided into several genera, from the proportion of the antennæ and palpi. We shall give as many examples as we can; but we must refer to a work which he is about to publish, entitled Trichoptera Systematica, for a more particular account, and for the characters of these genera, and of others named, 1. Ceratella, 2. Göresa, 3. Potomaria, 4. Prosoponia, 5. Chimarra, 6. Tinodes, 7. Philoptopus, and 8. Neurobia.

 Tribe I. Leptocerides.

Antennæ much longer than the whole body.

Genus CCCCLXXVI. Leptocerus. Leach's MSS.

Antennæ simple, not denticulated.

Sp. 1. Interrotus.

Phryganea interrotus. Fabricius.

Leptocerus interrotus. Leach's MSS.

Inhabits Great Britain. It is found in great plenty near Luss, on the banks of Loch Lomond, on the margins of rivulets at Dregen near Edinburgh, and near Carlisle in northern England. It occurs during the day time on the smaller branches of trees, and in the afternoon flies about in great abundance, in flocks.

Genus CCCCLXXVI. Odontocerus. Leach's MSS.

Antennæ with their inner edge denticulated.

Odontocerus griseum. Leach's MSS.

Inhabits Ireland and England. It is common at Dunlough Gap, near Kilbrany; and near Carlisle, on the banks of the Eden river. It has likewise been taken in Norfolk by Mr Scales, near Cheltenham, and near Plymouth, by Dr Leach.

Tribe II. Phryganides.

Antennæ as long as the body.

Genus CCCCLXXVII. Phryganea. Leach's MSS.

Anterior wings soft, villous.

Inhabits Europe.

Genus CCCCLXXVIII. Limnephilus. Leach's MSS.

Anterior wings slightly coriaceous, nervures hispid or hairy.

Phryganea rhombica. Linn.

Limnephilus rhombicus. Leach's MSS.

Inhabits Europe.

Order XIII. Neuroptera.

Genus CCCCLXXXIX. Libellula. Linn. Fabricius.

Libellula, Leach.

Posterior wings alike in both sexes.

Libellula depressa. Linn. Fabr. Latr.

Sp. 2. Conspectra.

Sp. 3. Quadrinaculata.

Libellula quadrinaculata. Donovan.

Sp. 4. Cancellata.

Libellula cancellata. Linn. Donovan.

Inhabits Europe. Is common on the Croydon Canal, near London.

Sp. 5. Vulgata.

Sp. 6. Donovani.

Libellula Donovani. Leach.

Libellula biguttata. Donovan.

Sp. 7. Scotica.

Libellula Scotica. Leach. Donovan.

Genus CCCCLI. Cordulegaster. Leach's MSS.

Posterior wings in the male produced into an angle at the anal edge.

Libellula anca. Linn. Donovan, Panzer, Latreille.

Cordula anca. Leach's MSS.

Family II. Libellulidae.

Wings horizontal. Head hemispheric, with a distinct vesicle on which the little eyes are placed in a triangle. Abdomen more or less depressed. Lip with the middle lamella smallest.

Genus CCCCLXXXVIII. Libellula. Linn. Fabricius.

Libellula, Leach.

Posterior wings alike in both sexes.

Libellula depressa. Linn. Fabr. Latr.

Sp. 2. Conspectra.

Sp. 3. Quadrinaculata.

Libellula quadrinaculata. Donovan.

Sp. 4. Cancellata.

Libellula cancellata. Linn. Donovan.

Inhabits Europe. Is common on the Croydon Canal, near London.

Sp. 5. Vulgata.

Sp. 6. Donovani.

Libellula Donovani. Leach.

Libellula biguttata. Donovan.

Sp. 7. Scotica.

Libellula Scotica. Leach. Donovan.

Genus CCCCLI. Cordulegaster. Leach's MSS.

Cordula anca. Leach's MSS.

Family II. Libellulidae.

Wings horizontal. Head hemispheric, without a distinct vesicle for the little eyes, which are arranged in a straight line. Abdomen cylindric, sometimes clavate. Lip with the middle lamella not much smaller than the others.

Genus CCCCLXXXIX. Cordulegaster. Leach's MSS.

Libellula. Linn. Donovan.

Aeshna. Latreille.

Hind wing of the male angulated at their anal
Metaboli. edge. Abdomen of the male clavate, of the female with an acuminate process.

Annulat. 

482. Gom. 

Genus CCCCLXXII. Gomphus. Leach’s MSS. Libellula. Linn. Donovan. Wings of the male angulated at their anal edge. Abdomen clavate in both sexes.

Vulgatissimus. 

Grandis. 

Obs. There are several European species, which have been confounded with Aeshna grandis.

484. Anax. 

Genus CCCCLXXIV. Anax. Leach’s MSS. Hinder wings of the male not angulated at their anal edge, but resembling those of the female. Abdomen cylindric in both sexes; not clavate.

Imperator. 

Family III. Agrionida.

Obs. We have of this genus several indigenous species, not accurately determined.

486. Lestes. 

Genus CCCCLXXVI. Lestes. Leach. Wings membranaceous, with an oblong quadrate stigma. Abdomen of the male armed with a forceps-like appendage.

Obs. We have three indigenous species.

Genus CCCCLXXVII. Calopteryx. Leach’s MSS. Agrion. Fabricius Latreille. Wings coriaceo-membranaceous, without a real stigma, in place of which is sometimes an irregular opaque spot. Abdomen of the male furnished with a forceps-like appendage.

Obs. This genus comprehends those Agrionida with coloured wings.

Tribe II. Ephemерides.

Tarsi four-jointed. Mouth not distinct. Inferior wings much smaller than the others, sometimes wanting. Abdomen with the extremity furnished with filaments.

Metamorphosis quadraple.
ENTOMOLOGY.

Wings vary: triangle. -i:

Inhabits southern France.

Tribe II. Myrmeleonides.

Antennae thicker towards their extremities. Palpi six. Wings equal. Tarsi five-jointed, the first and last joints longest; claws two, strong, elongate, acute.

Antennae gradually thicker towards their extremities; shorter than the body. Eyes entire. Abdomen very long, linear. Labial palpi very long, apex obconic, truncate.

Sp. 1. Libelluloides. Body yellow, lineated with black; antennae black; wings hyaline, with distant spots and points of blackish colour; under wings less maculated, with two abbreviated blackish bands; feet variegated.

Sp. 4. Formicarius. Wings hyaline, apex acute maculated with fuscous; costal mark and some Anastomoses whitish.

Sp. 5. Formicarius. Leach's MSS. Inhabits Europe in sandy districts; it varies with immaculate wings.

Genus CCCXCVI. Ascalaphus. Fabricius, Latreille, Linn. Thorax and abdomen of this species are as follows:

Barbarus. Body black spotted with yellow; wings nervured with golden yellow; upper ones from the base of the hinder margin even to the border, blackish, the border broadly paler; inferior ones with the base blackish, hyaline, in the middle, the apex blackish.

Sp. 3. Ascalaphus. Fabricius, Latreille. Inhabits southern Europe and part of Germany.

Tribe III. Hemerobidae.

Antennae filiform or setaceous. Palpi four. Wings equal. Tarsi five-jointed.

Family I. Hemerobida.

Genus CCCXCVII. Chrysopa. Leach's MSS. Hemerobius. Linne, Geoffroy, Fabricius, Latreille, Olivier, Lamarck. Antennae (at least as long as the body) with cylindrical joints longer than broad.

Genus CCCXCVIII. Hemerobius. Linne, Fabricius, Latreille, Leach. Antennae as long, or shorter than the body, joints moniliform.

Family II. Osmylida. Ocelli three distinct.

Tribe IV. Corydalidae.

Thorax with the first segment large, not much longer than broad. Tarsi five-jointed. Wings of equal size. Feet resembling each other.

Family I. Corydalida.

Obs. Latreille considers this genus akin to Raphidius, notwithstanding the difference of the tarsal joints, both in number and form.

ENTOMOLOGY.

Family II. Siatida.
Wings deflexed. Tarsi with the last joint but one bilobed. Ocelli none.

Genus DIII. Sialis. Latreille.
Hemerobius. Geoffroy, De Geer, Olivier.
Semblis. Fabricius.

Genus IV. Siatis. Latreille.
Hemerobius. Geoffroy, De Geer, Olivier.
Semblis. Fabricius.

Tribe V. Mantispides.
Anterior feet raptorial. Thorax with the first segment large, long. Tarsi five-jointed. Wings of equal size, deflexed.

Genus DIII. Mantispa. Illiger, Latreille.
Raphidia. Scopoli, Linnaeus.
Mantis. Fabricius, Pallas, Olivier.
Nerveurs hairy.

Mantispa pagana. Illiger, Latreille.
Raphidia mantispa. Scopoli, Linnaeus.
Mantis pera. Pallas.
Mantis pagana. Fabricius, Panzer.
Inhabits France and Germany.

Tribe VI. Raphidides.
Wings of equal size. Thorax with the first segment large. Tarsi with four distinct joints, the last but one bilobate. Antennae nearly setaceous. Ocelli three, arranged in a triangle.

Head oval, narrowed behind, inflexed. Thorax with the first segment very long, narrow, and somewhat cylindrical. Anus of the females with two united setae.

Raphidia ophiopis. Linn. Fabr. Latr.
Inhabits Europe.

Tribe VII. Termitides.
Wings of equal size, horizontally incised. Thorax with the first segment large. Tarsi with three distinct joints, the penultimate joint entire. Antennae moniliform, inserted before the eyes. Head short, rounded behind. Ocellus one.
The animals of this tribe congregate in great numbers, and live in societies, being generally known by the term white ants, a name applied to all the species indiscriminately.

Hemerobius. Linn.

Lucefugum. Sp. 1. Lucefugum. Black, shining, and pubescent; thorax transversely quadrate, with the angles rounded, with an impression on each side of the anterior part, the intermediate space somewhat carinated; wings fuscous-livine, the costa blackish; apex of the joints of the antennae, tibie, (base excepted), and all the tarsi, pale-redish.

Termes lucefugum. Rossi, Latreille.
Inhabits Italy.

Tribe VIII. Psocides.
Inferior wings smaller than the superior ones. Some are apterous. Palpi two, composed of four joints.

Hemerobius. Linnaeus.

Psocus bipunctatus. Variegated with yellow and black; head above the clypeus black; superior wings with a small costal mark, and another on the opposite margin black; the interjected cords blackish; stigma white, with a black spot.

Psocus bipunctatus. Latreille, Fabricius, Coquebert. Linnaeus.
Inhabits Europe.

Family II. Atropida.
Tarsi three-jointed.

Genus DVI. Atropos. Leach's MSS.
Psocus. Fabricius, Latreille, Coquebert.
Pediculus. (Pou.) Geoffroy.

Termes pulitorium. Linn.
Termes lignarius. De Geer.
Psocus pulitorius. Fabricius, Latreille, Coquebert.
Inhabits old books, often beating like a watch, whence it has acquired the name of death-watch.

Psocus fatidicus of Fabricius, is referable to the genus Atropos, but whether it be a distinct species from Atropos lignaria is certainly very doubtful.

Tribe IX. Perlariides.
Inferior wings larger than the superior ones, with longitudinal folds. Tarsi with three joints. Mandibles distinct. Thorax with the first segment large.

Obs. The wings horizontally incised.

Genus DVIII. Nemoura. Latreille.
Phryganea. Linnaeus.
Semblis. Fabricius.
Labrum very distinct, almost semicircular. Mandibles cornaceous. Palpi filiform. Tarsi with equal lengthened joints (the middle one scarcely shorter) not spongy beneath. Anus without setae.

Sp. 1. Nebulosa. Fuscous-black, pubescent; abdomeen and feet reddish-fuscous; wings cinereous, immaculate, the nerveurs darker.

Le Perle Brun. à ailes pâles. Geoffroy.
Nemoura nebulosa. Latreille.
Inhabits Europe.

Phryganea. Linnaeus.
Semblis. Fabricius.
Labrum obscure, transversely linear. Mandibles almost membranaceous. Palpi almost setaceous. Tarsi with the two basal joints shorter than the third. Anus with two long setae.

Perla marginata. Latreille.
Inhabits Europe.

Phryganea bicaudata of Linnaeus belongs to this genus.
ENTOMOLOGY.

Order XIV. Hymenoptera.

Class Pherata. Fabricius.

Characters of the Order.

Wings narrower, (the aedece large and unequal in size,) the inferior ones smaller than the upper. Anus of the females with a sting or an oviduct.

Section I. Terebrantia.

Oviduct lamelliform or filiform, in a few resembling a sting and valved; the vagina bivalve, received in a canal beneath the anus, the valves compressed, in some compressed lamelliform; in others elongate-cylindric, sectaceous.

Division I.

Abdomen united to the thorax along its whole breadth, without any distinct peduncle.

Tribe I. Tenthredinidae.

Abdomen sessile. Oviduct composed of two lamellae which are serrated. Mandibles more or less long, terminated by two strong teeth. Wings with the marginal cells complete.

Family I. Tenthredinidae.

Labrum distinct. Larve with membranaceous feet.

Cimex. Geoffroy.

Antenna terminated by a distinct club, nearly ovoid. Genus this genus is artificial; it contains several natural genera, which may be defined from the joints composing their antenna.

Antenna with five joints before the club, which is nearly solid.

Antenna with five joints before the club, which is distinctly articulated.

Sp. 3. Leucorum. Fabricius.

Antenna with four joints before the club, which is distinctly articulated.

Antenna with four joints before the club, which is two-jointed.

Tenthredo sericea and nits of Linnaeus are but sexual distinctions of the same species.

Cryptus. Jurine.

Arce. Schrank.

Antenna gradually thickening towards their extremities, composed of three joints. Superior wings with four submarginal cells, and one marginal cell emitting a little branch.

Inhabits Europe.

Obs. Hylotoma furcata of Latreille, Tenthredo furcata of Panzer, and its congeners, are distinguished from the genuine Hylotoma, by having filiform bifurcate antenna, and should constitute a peculiar genus.

Allantus. Jurine.

Antenna simple, composed of nine joints. Superior wings with two marginal and with four submarginal cells.

Allantus scrophulariae. Jurine.

Inhabits Scrophularia nodosa and aquatic when in flower.

Inhabits grassy places and the margins of woods.

Dolerus. Fabricius, Linneus.

Antenna simple, nine-jointed. Superior wings with two marginal and three submarginal cells.

Tenthredo gonager. Fabricius, Panzer.

Inhabits Europe.

Antenna simple, nine-jointed. Superior wings with one marginal and four submarginal cells.

Inhabits the European woods.

Genus DXV. Pristiphora. Latr.

Pertoni. Jurine.

Antenna simple, nine-jointed. Superior wings with one marginal and three submarginal cells. Mandibles bidentate.

Pristiphora testacea. Latr.

Genus DXVI. Cladius. Latr. Illiger.

Cladius. Panzer.

Antenna nine-jointed, branched in the male, simple in the female. Superior wings with one marginal and four submarginal areole or cells. Mandibles bidentate.

Clastis diforinis. Latr.

Inhabits Europe.

Genus DXVII. Lophurus. Latr.

Lophurus. Jurine.

Hylophora. Fabr.

Antenne pinnate in the males, serrated in the females. Superior wings with one marginal and three submarginal cells. Mandibles tridentate.

Metabolia.

Hylotoma pini. Fabr.
Lophyrus pini. Latr.
Inhabits Europe.

**Family II. Xiphydrida.**

Labrum obscure. Larvae with scaly feet, or at least membraneous.

Sphex. Scopoli.
Mandibles with their internal edge not dentated.
Maxillary palpi long and pendulous. Antenna filiform, compressed, inserted under the anterior margin of the eye. Superior wings with one marginal cell, and two submarginal, the last incomplete. Oviduct capillary, hidden in a longitudinal groove.

Sphex abietina. Scopoli.
Inhabits Europe.

**Genus DXXII. Urocerus.** Geoff. Schaaff. Oliv. 522. Uro-
Lam. Latr. Leach.
Mandibles dentated on their internal edge. Maxillary palpi very small. Labial palpi terminated by a very thick, hairy joint. Antenna gradually narrowing externally, inserted in the front; longer than the thorax. Superior wings with two marginal and two submarginal cells complete. Abdomen terminating in a point. Oviduct exserted, composed of three parts, the outer ones valviform.

**Obs.** This genus contains two great divisions, which, from their characters, are evidently natural genera.

**Genus Urocerus.** Leach.
Sirex marinus. Fabr. (Male).
Sirex gigas. Linn. Fabr. Latr. (Female).
Urocerus gigas. Latr.
Inhabits Europe. Is rare in Britain.

Inhabits Europe. Was taken near Edinburgh by Mr John Wilson, of the College, Edinburgh.

** Antenna with 21 or 23 joints. Maxillary palpi with their basal joint very short, scarcely to be found.

A. Abdomen of the female terminated by an abrupt, elongate horn. Labial palpi distinctly trissected.

**Genus Sirex.** Leach.
Urocerus spectrum. Latr.
B. Abdomen of the female with the extremity gradually acuminate.

Urocerus juvenus. Latr.
Sirex juvenus. Leach.
Inhabits Europe. Is rare in Britain.

**Genus DXXIV. Tremex.** Latr.

**TRIBE II. UROGERIDE.**

Abdomen sessile. Oviduct filiform, exserted, or inscribed in a groove beneath the abdomen. Mandibles short.

* This tribe, Dr Leach has proposed to divide into two families, the one to contain the genus Oryssus, the other Sirex, Urocerus and Tremex.
in the front. Superior wings with two marginal, and two submarginal cells, complete. Abdomen terminating in a point. Oviduct exserted, composed of three parts, the outer ones valviform.

Tribe III. Evaniidae.

Abdomen united to the thorax by a slender peduncle.

Tribe IV. Ichneumonidae.

Abdomen attached to the thorax by a part of its transverse diameter. Inferior wings with very distinct nervures. Antenne with 21 joints and more.

Family I. Stephanida.

Mandibles terminated by an entire point, or with but a very obscure notch. Head globose.

Thorax much attenuated anteriorly. Metathorax cylindric, straight or horizontal. Abdomen inserted at the superior and posterior extremity of the metathorax, the first segment abruptly narrower than the rest.

Inhabits Germany.

Metathorax with the hinder segment convex, and at the apex rounded. Abdomen distinctly pedunculated, inserted under the posterior and superior apex of the metathorax.

Inhabits Europe.

Family II. Ichneumonida.

Mandibles bidentate, or notched at their extremity.

Division I.

Abdomen with five very distinct segments.

Subdivision 1.

Superior wings with the first submarginal cell very large; the two discoidal cells situated longitudinally, one above the other.

Genus DXXXI. Ichneumon. Latreille.

Maxillary palp with very unequal joints. Oviduct with its base not covered by a large scale, exserted.

Obr. This genus, which has been attentively examined by Latreille, consists of several natural genera; but the characters are obscure, and are not yet fully understood. Under this head, the following genera, (or parts of them), proposed by Jurine, Fabricius, Panzer, Illiger, and Walckenaer, are comprehended; viz. 1. Cryptus, 2. Basus, 3. Pimpla, 4. Joppa, 5. Metopius, 6. Trogas, 7. Atomya, 8. Pelastus, 9. Ophius, and 10. Banchus.
The following divisions are proposed by Latreille, who has submitted these insects to a scrupulous and daily investigation.

**Division A.**
Abdomen but little or not at all compressed.

**Subdivision a.**
Extremity of the abdomen of the female compressed, and obliquely truncated ; oviduct exserted.

1. *Abdomen cylindrical, with a very short peduncle.*
   - **Genus Pimpa of Fabricius.**

2. **Abdomen somewhat ovoid, with the peduncle long, slender, and arcuate.**
   - **Genus Cryptus of Fabricius.**

**Subdivision b.**
Extremity of the abdomen of the female slightly compressed, not obliquely truncated; oviduct scarcely prominent or exserted.

3. *Abdomen cylindrical, almost sessile.*
   - **Genus Metopius of Panzer; Pelastes of Illiger.**

4. **Abdomen almost fusiform or cylindrical, gradually narrower towards the base; the peduncle not slender or arcuate.**
   - **Genus Aloeomyia of Panzer.**

5. ***Abdomen ellipsoid or ovoid, with the peduncle slender and arcuate.**
   - **Genus Ichneumon of Fabricius.**

**Division B.**
Abdomen very much compressed.

6. *Abdomen, apex truncate in the females.*
   - **Genus Opinion of Fabricius.**

7. **Abdomen with the apex pointed.**
   - **Genus Banchus of Fabricius.**

---

**Family III. Alysiida.**

Mandibles tridentate at their extremities, forming an irregular square.

**Genus DXXVII. Alysius. Latr.**
   - **Cryptus. Fabricius.**
   - **Banchus. Panzer.**
   - **Cechinus. Illiger.**
   - **Sp. 1. Manducator.**
   - **Cryptus manducator. Fabricius.**
   - **Banchus manducator. Panzer.**

**Tribe X. Diplolepides.**

Abdomen inserted to the thorax by a part only of its transverse diameter. Superior wings without distinct nervures. Body not contractile into a sphere. Abdomen compressed or depressed. Oviduct filiform. Palpi very short. Antennae filiform, straight, from thirteen to sixteen-jointed.

**Family I. Diplolepidida.**

Abdomen very shortly, or not at all pedunculated.

**Genus DXXVIII. Alysius. Latreille, Illiger.**
   - **Banchus. Fabricius.**
   - **Sagaris. Panzer.**
   - **Cynips. Jurine.**

Panzeri.

---

**Genus DXXXV. Microaesther. Latreille, Illiger, Spinoli.**
   - **Ichneumon. Linnaeus, Fabricius, Jurine, Ross.**
   - **Cero-plas. Fabricius.**
   - **Cryptus. Fabricius.**
   - **Banchus. Panzer.**

Mouth not produced. Abdomen very small and depressed. Oviduct short. Superior wings with one marginal cell nearly obsolete in some, and three submarginal; the second minute, the last terminal imperfect.

**Sp. 1. Deprimalor.**
   - **Ichneumon deprimalor. Fabricius.**

**Microaesther deprimalor. Latreille.**
Inhabits Germany.

**Division II.**
Abdomen almost inarticulate, with but three distinct segments.

**Genus DXXXVI. Sigalphus. 'Latreille, Spinoli.**
   - **Spheroptyx. Hoffmansegg.**
   - **Cryptus. Fabricius.**
   - **Ichneumon. Fabricius.**
   - **Chelonus. Jurine, Panz. Illiger.**
   - **Banchus. Jurine.**
   - **Sp. 1. Irrinator.**
   - **Sigalphus irrator. Latreille.**
   - **Cryptus irrator. Fabricius.**

**Family III. Alysiada.**

Mandibles tridentate at their extremities, forming an irregular square.

**Genus DXXVII. Alysius. Latr.**
   - **Cryptus. Fabricius.**
   - **Banchus. Panzer.**
   - **Cechinus. Illiger.**
   - **Sp. 1. Manducator.**
   - **Cryptus manducator. Fabricius.**
   - **Banchus manducator. Panzer.**

**Inhabits Germany.**

---

**Genus DXXXII. Acenitus. Latr.**
   - **Cryptus. Fabr. Panzer.**
   - **Ichneumon. Schaeffer, Scopoli, Oliv.**
   - **Anomalia. Jurine.**

Palpi with their joints not very unlike each other. Oviduct covered at its base by a large scale.

**Dubitator.**
   - **Sp. 1. Dubitator.**
   - **Cryptus dubitator. Fabr. Panzer.**
   - **Acenitus dubitator. Latr.**
   - **Inhabits Germany.**

**Subdivision 2.**
Superior wings with the first submarginal cell small, or moderately sized; the two discoidal cells placed in a transverse line by the side of each other.

**Genus DXXXIII. Braccon. Jurine, Fabr. Panzer, Illiger, Spinoli, Latr.**
   - **Ichneumon. Linnaeus, Scopoli, Schrauk.**
   - **Vipio. Latr. (Rejected name).**

Mouth produced into a rostrum. Superior wings with the two first submarginal cells nearly equal, square.

**Descr.**
   - **Sp. 1. Descr.**
   - **Braccon descr. Fabr. Latr.**

**334. Agathis.**
   - **Genus DXXXIV. Agathis. Latr.**
   - **Ichneumon. Jurine.**
   - **Braccon. Fabr. Spinoli.**

Mouth produced into a rostrum. Superior wings with the second submarginal cell very small.

Panzeri.
   - **Sp. 1. Panzeri.**
   - **Ichneumon panzeri. Jurine.**
   - **Agathis panzeri. Latreille.**

---

**Genus DXXXV. Microaesther. Latreille, Illiger, Spinoli.**
   - **Ichneumon. Linnaeus, Fabricius, Jurine, Ross.**
   - **Cero-plas. Fabricius.**
   - **Cryptus. Fabricius.**
   - **Banchus. Panzer.**

Mouth not produced. Abdomen very small and depressed. Oviduct short. Superior wings with one marginal cell nearly obsolete in some, and three submarginal; the second minute, the last terminal imperfect.

**Sp. 1. Deprimalor.**
   - **Ichneumon deprimalor. Fabricius.**

**Microaesther deprimalor. Latreille.**
Inhabits Germany.
ENTOMOLOGY.

541. EC-CHARIS.

Abdomen with a very distinct elongate peduncle.

** Abdomens with six joints, one shorter than the one before it.

Chalcis clavipes. Latreille.
Inhabits Europe.
** Abdomen with a very short peduncle.

Chalcis minuta. Fabricius, Panzer, Latreille.
Inhabits Europe.

Family II. Cynipida.

Hinder tibiae very much arcurated.

Vespa. Sulzer, Christus.

Abdomen as if sessile, somewhat ovate, compressed, thicker above. Maxillary palpi with the second and third joints equally long, the superior wings longitudinally dilated and the second and third marginal cells distinctly abbreviated, open.

Gigas.

Leucopsis gigas. Fabr. Latr.
Inhabits France and Germany.

Sphex. Linnaeus.
Vespa. Linnaeus.

Abdomen ovoid-triangular, not sessile, terminated by a point. Superior wings not folded, with the marginal and submarginal cells none or obliterated. Maxillary palpi, with the last joint but one shorter than the one before it.

Chalcis clavipes. Latreille.
Inhabits Europe.

Chalcis minuta. Fabricius, Panzer, Latreille.
Inhabits Europe.
DIVISION II.

Thorax with the anterior segment very short, transverse-linear.

Subdivision 1.

Mandibles almost quadrate, with three or four distinct teeth.

Genus DXLIX. Perilampus. Latreille.

Diaprius. Fabricius, Illiger, Panzer, Spinolii.

Chalcis. Rossi, Chvler, Lamarck, Jurine.

Cynips. Olivier, Walckenaer.

Mandibles strongly toothed. Club of the antennae short, fusiform.

Viaceaeus.

Diaprius violaceus. Fabricius.

Perilampus violaceus. Latreille.

Sulcata.

Abdomen Phoctotrupides.

38. Kugii-m. 

549. Violaceiu.

Thorax 

DiPLoLEPis. 

Mandibles 

Cleptes. 

Cynips. 

Pieromatus tortricis. Latreille.

Subdivision 2.

Mandibles terminated in a point, with two or more teeth.

Genus DLI. Encyrtus. Latreille.

Ichneumon. Rossi.

Mira? Schellenberg.

Mandibles terminated with but one tooth. Abdomen very short, trigonate. Head much compressed behind. Scutellum large.

Infidus.

Sp. 1. Infidus.

Ichneumon infidus. Rossi.

Encyrtus infidus. Latreille.

Mira maccorn? Schellenberg?

Inhabits Europe.

Genus DLII. Platygaster. Latreille.

Schelio. Latreille, (rejected name.)

Mandibles terminated by two teeth. Abdomen elongated, depressed. Antennae ten-jointed; the first joint very long, the third much longer than the following joints. Head trigonate-globose.

Ruficornis.

Platygaster ruficornis. Latreille.

Inhabits France.

Genus DLIII. Schelio. Latreille.

Ceraphronus? Jurine, Spinola.

Mandibles terminated by two teeth. Abdomen elongated, depressed. Antennae ten-jointed, the first and third joints but little lengthened.

Rugulosus.

Schelio rugulosus. Latreille.

Genus DLIV. Telias. Latreille.

Brevicornis.

Telias brevicornis. Latreille.

TRIBE VII. PROCTOTRUPIDAE.

Abdomen attached to the metathorax by a portion of its transverse diameter. Inferior wings without distinct nervures. Body not contractible into a ball. Abdomen compressed, or depressed, the hinder extremity produced into a point or tubular tail, which is univalve or bivalve. Maxillary palpi long and pendant.

DIVISION I.

Thorax not binodate, the anterior segment transverse, arcuate.

Subdivision 1.

Antennae with the first joint very long; inserted towards the mouth.

Genus DLV. Sparasson. Latreille.

Ceraphron. Jurine.

Antennae twelve-jointed. Abdomen elliptic, depressed, without any very distinct peduncle.

Sp. 4. Frontale.

Sparasson frontale. Latreille.

Ceraphron cornutus. Jurine, (female.)

Inhabits France.

Antennae eleven-jointed. Abdomen ovoid, compressed, pedunculated distinctly.

Antennae ten-jointed. Abdomen very distinctly and abruptly pedunculated, ovoid and depressed.

Anteon jurineanum. Latreille.

Subdivision 2.

Antennae inserted towards the middle of the face, or in the front, the first joint very long.

Genus DLVIII. Psilus. Jurine, Panzer, Spinola.

Diapria. Latreille.

Cleptes. Fabricius.

Ichneumon. Villers, Rossi.

Antennae moniliform; of the males fourteen-jointed; of the females twelve-jointed. Superior wings with no cells; the costal nerve abbreviated, thicker towards its extremity.

Psilus cornutus. Panzer.

Diapria cornuta. Latreille.

Inhabits Europe.

Cinclus. Jurine.

Antennae filiform; of the male fifteen; of the female fourteen-jointed; all the basal joints elongate. Superior wings with the cells complete.

Subdivision 3.

Antennae with the first joint not elongate.

Genus DLX. Proctotrephes. Latreille, Spinola.

Cerditus. Jurine, Panzer.

Eriodus. Walck.

Antennae thirteen-jointed. Mandibles without teeth. Superior wings with three complete cells. Abdomen scarcely pedunculated, terminated by a joint more or less long.

Inns. 4. 38. tab. 13. fig. 1.

Inhabits Europe.

Spinex. Panzer.

561. Helorus.
ENTOMOLOGY.

Antennae fifteen jointed. Mandibles dentated. Superior wings with more than three complete cells. Abdomen distinctly and abruptly pedunculated, not terminated in a point.

Sphecos anomalous. Panzer.
Hedora anomalous. Latreille.
Inhabits Germany and France.

DIVISION II.

Thorax binaudiate, the anterior segment elongate-quadrate, or somewhat triangular. Antennae inserted on the clypeus, near the mouth.

GENUS DLXII. Daivinus. Latreille.
Gonatopus. Klug.
Antennae straight, ten-jointed. Mandibles with many teeth. Thorax binaudiate. Anterior feet very long, terminated by two very large nails internally denticulated, one of these reflexed.

Dryinus fornicarius. Latreille.
Inhabits France.

GENUS DLXIII. Bathyulus. Latreille, Fabricius, Illiger, Spinola.
Omalus. Jurine.
Ceraphion. Panzer.

Bathyulus cenopterus. Latreille.

TRIBE VIII. CHRYSIDIDES.

Abdomen attached to the metathorax by a portion only of its transverse diameter. Inferior wings without distinct nervures. Body not contractable into a ball.

FAMILY I. Cleptida.

Abdomen semicylindric or semicircular, with five segments in the male, and four in the females. Thorax attenuated in front, divided transversely by four segments.

GENUS DLXIV. Cleptes. Latreille, Fabricius, Panzer, Jurine, Illiger, Spinoli.
Sphex. Linn. Vill.
Chrysis. Olivier.
Vespa. Geoffroy.
Ichneumon. Rossi, Walck.
Cleptes seminaturae. Fabricius, Latreille.
Inhabits Europe.

FAMILY II. Chrysidida.

Abdomen semicylindric, truncated or rounded behind, often dentated, composed of three, sometimes of four joints. Thorax semicylindric, divided by three transverse sutures.

DIVISION I.

Metathorax with the middle produced into a scutellum.

Subdivision 1.

Abdomen with the second segment larger than the others. Palpi many-jointed.

GENUS DLXV. Elampus. Spinoli.
Chrysis. Fabricius, Jurine.
Hedychrum. Panzer, Lepeletier.

Mandibles dentated. Abdomen terminated by an obtuse point; the second segment larger than the others.

Elampus panzeri. Spinoli.
Chrysis panzeri. Fabricius.
Inhabits France and Germany.

GENUS DLXVI. Stilbum. Spinoli, Latreille.
Chrysis. Linn. Olivier, Illiger, Jurine.
Mandibles without teeth. Abdomen with the third segment very large, slightly dentate behind.

Chrysis splendidus. Fabricius, Donovan.
Inhabits India.

Subdivision 2.

Abdomen with the third or fourth segment larger than the others. Palpi two-jointed, (and very small.)
GENUS DLXVII. Parnopes. Latreille, Fabricius, Spinoli, Illiger, Lepeletier.
Chrysis. Rossi, Olivier, Jurine.
Parnopes carnea. Latreille.
Inhabits France and southern Italy.

DIVISION II.

Metathorax with the middle not elongated into a scutellum.

GENUS DLXVIII. Euchres. Latreille.
Chrysis. Fabricius, Jurine, Lepeletier.
Mandibles with one tooth on their internal edge. Abdomen semicylindric, elongate, the last segment with a transverse elevation, and a row of impressed dots.

Chrysis purpuratus. Fabricius.
Euchres purpuratus. Latreille.
Inhabits France.

GENUS DLXIX. Chrysis of authors.
Vespa. Geoffroy.
Mandibles with one tooth on their internal edges. Abdomen semicylindric, elongate; the last segment abruptly divided by an impression, with a transverse row of impressed dots.

Sp. 1. Ignita.
Chrysis ignita. Linn. Fabricius, &c.
Mandibles bidentate on their internal edge. Abdomen semicircular, with the extremity rounded; all the segments united.

Chrysis aurata. Fabricius.

SECTION II. ACULEATA.

Oviduct none. Sting or aculeus in the females having a communication with poisonous glands. Abdomen attached to the thorax in all by a part only of its transverse diameter.

DIVISION I.

Hinder feet not pollinigers; their tarsi with the first joint cylindric, not much larger than the others, nor much compressed. Larve omnivorous.

Subdivision 1.

Ocelli or stemmata not distinct. Wings often wanting in the females and neuters.
ENTOMOLOGY.

TRIBE I. Formicarides.*

Abdomen with a peduncle abruptly formed, with a scale on two knots. Antennae thicker towards their extremities, the first joint very long, more so in the females and neuters. Labrum large, perpendicular, cornous.

Obs. These insects live in societies consisting of vast numbers. The males and the females are furnished with wings, the neuters being aperous.

GENUS DLXXI. Formica of authors.

Lasiurus, Fabricius.

Peduncle of the abdomen formed of one simple scale. Sting not punctorous. Poisonous glands in the females and neuters. Antennae inserted in the front.

Inhabits the European woods, building a large nest with bits of sticks.

GENUS DLXXII. Polyergus. Latreille, Spinoli.

Formica. Jurine.

Peduncle of the abdomen formed of but one simple scale. Sting not punctorous. Poisonous glands in the females and neuters. Antennae inserted near the mouth.

Sp. 1. Polyergus.

Polyergus rufescens. Latreille.

GENUS DLXXXIII. Ponera. Latreille, Illiger.

Peduncle of the abdomen formed of two knots. Sting in females and the neuters.

Ponera chelifer. Latreille.

** Mandibles of the neuters broad and triangular. Genus Ponera of Latreille's older works.

Formica crassinoda. Fabricius.

Ponera crassinoda. Latreille.

Peduncle of the abdomen formed of two knots. Sting in the females and the neuters. Antennae entirely exserted. Palpi very short; maxillary ones with six distinct joints. Head of the neuters very large.

* Mandibles of the neuters very narrow, and much elongated.

Genus Ecton of Latreille's older works; Myrmecia, Fabr. us.

Myrmecia hamata. Fabricius.

A. Hamata. Latreille.

** Mandibles of the neuters elongate-trigonate, much denticulated.

Formica of Latreille's older works; Atta, Fabr.

Atta cephalotes. Latreille, Fabricius.

** Mandibles of the neuters short, trigonate, scarcely denticulated.

Genus Formica of Latreille's older works, and of Fabricius.

Capitata. Sp. 3. Capitata.

Atta capitata. Latreille.

GENUS DLXXV. Myrmica. Latr. Spinoli.

Manica. Jurine.

Myrmecia. Fabricius.

* Mandibles very narrow, very long: Antennae filiform.

Myrmica forficata. Latr.

** Mandibles trigonate, but little elongate: Antennae thicker towards their extremities.

a. Superior wings with three submarginal cells; the first and second perfect.

b. Superior wings with two submarginal cells; the first perfect.

Formica. Linn. Olivier.

Manica. Jurine.

Cryptocerus atratus. Latr.

TRIBE II. Mutillarides.

Antennae filiform, vibratory, the first and third joints elongate.

The insects of this family are solitary. The males are winged, the females aperous, and there are no neuters.

FAMILY I. Dorylida.

Antennae inserted at the mouth, the first joint very long. Head small. Abdomen cylindric, having the first joint nearly trigonate, with the superior sides more elevated, or transverse; rounded above, and separated from the following joint by an incision. Tibia slender, not spinose.

Abdomen with the first segment nearly trigonate, with the sides elevated like a horse's shoe. Superior wings with three submarginal cells.

Dorylus medius fabricius is probably to be referred to this genus.

GENUS DLXXVIII. Dorylus.† Fabricius, Jurine, 578. Dorylus. Dorylus Illiger, Olivier, Latreille.

Abdomen with the first segment transverse, rounded above, and separated from the following joint by an incision. Superior wings with two submarginal cells.

FAMILY II. Mutillida.

Antennae inserted in the middle of the face. Head large. Abdomen somewhat conic or ovoid. Tibia spinose.

A. Huber has written a work on the economy of these animals.

† The males only of this and the preceding genus are known; the females are supposed to be aperous and solitary.
ENTOMOLOGY.

DIVISION I.

Abdomen with the two first segments nodiform. Superior wings with one submarginal cell.

\[ \text{Genus DLXXXIX. Apterogyna. Latreille.} \]

Antennae setaceous, of the male as long as the body, of the females a little shorter. Mandibles arcuate. Maxillary palpi long.

\[ \text{Sp. 1. Olivieri. Apterogyna Olivieri. Latr. Inhabits Arabia.} \]

DIVISION II.

Abdomen with the first segment of the abdomen nodiform. Superior wings with three submarginal cells.

\[ \text{Subdivision 1.} \]

Maxillary palpi as long or longer than the maxilla. Antennae longer than the head, the first joint not receiving the second.

Abdomen (of both sexes) ovoid and convex, the second segment larger, somewhat constricted. Thorax of the females cubical, with no transverse sutures.

\[ \text{Genus DLXXXI. Methoca. Latreille.} \]

Mutilla. Jurine. Abdomen (of the females) ovoid and convex, with the second segment large. Thorax composed of three segments, nodose.

\[ \text{Sp. 1. Ichneumonomoeides. Methoca ichneumonomoeides. Latr. Inhabits Europe.} \]

\[ \text{Genus DLXXXII. Muremosa. Latreille. Jurine.} \]

Abdomen depressed, elliptic in the males, conic in the females. Thorax composed of two segments, the anterior segment transverse.

\[ \text{Sp. 1. Melicephala. Myrmecocysta melicephala. Latr.} \]

\[ \text{SCHLERODEIUS.} \]

Abdomen of the females conic. Thorax divided into three segments by two transverse sutures, the hinder one elongate.

\[ \text{Subdivision 2.} \]

Maxillary palpi shorter than the maxilla. Antennae slender, longer than the head; the first segment receiving the second.

\[ \text{Genus DLXXXIV. Myrmecodes. Latreille.} \]

Thyria. Fabricius. Mandibles porrect, arcuate, dentulous. Palpi very short, three or four-jointed, the last joint obsolete; labial palpi shorter, scarcely visible, somewhat conic; labial ones cylindrical. Antennae not much longer than the head. Thorax elongate-cubic, a little narrowed behind, composed of three segments meeting together, the first segment largest.

\[ \text{Subdivision 2.} \]

Ocelli distinct, smooth. Wings never wanting.

\[ \text{SUBDIVISION 2.} \]

THREE. SCOLIDES.

Thorax with the first segment transverse quadrato, or forming an arc. Feet short, or moderately long; the hinder ones thick, spinulose, or strongly ciliate. Antennae shorter than the head and trunk. Superior wings with the marginal cell detached from the apex; not doubled longitudinally.

\[ \text{FAMILY I. Tiphia.} \]

Maxillary palpi long, with the joints very unequal. Antennae with the first joint obconic.

\[ \text{FAMILY II. SCOLICA.} \]

Maxillary palpi short, joints equal. Antennae with the first joint long, nearly cylindrical.

\[ \text{DIVISION 1.} \]

Thorax with the anterior segment transverse-quadrato, the hinder margin straight or but little arcuate.

\[ \text{Genus DLXXXVII. Miltia. Latreille. Jurine.} \]

\[ \text{Sp. 2. F. Tiphia masu}. \]

\[ \text{SCHLERODEIUS.} \]

Mandibles bidentate.

\[ \text{Sp. 2. F. maculata. Tiphia maculata. Fabricius, Panz. Jurine.} \]

\[ \text{FAMILY II. SCOLICA.} \]

Mandibles without teeth. Antennae shorter than the thorax in both sexes. Abdomen ovate.

\[ \text{Sp. 1. F. sambu}. \]

\[ \text{FAMILY II. SCOLICA.} \]

Mandibles without teeth. Antennae shorter than the thorax in both sexes. Abdomen ovate.

\[ \text{Sp. 1. F. sambu}. \]
Superior wings with three submarginal cells, the last small; and two perfect discoidal cells. Four hinder tibiae with acute spurs or heel.

Hortorum.

Seclia hortorum. Fabricius, Latreille.

** Superior wings with three submarginal cells, the last small; and with three perfect discoidal cells. Hinder tibiae with the heels broader at their extremities, and rounded.

Interrupta.

Sp. 2. Interrupta.

Elis interrupta. Fabricius.

** Superior wings with two submarginal cells, the second receiving two recurrent nerves. Three perfect discoidal cells: Tibia as in the last division.

Abdominalis.

Sp. 3. Abdominalis.

Seclia abdominalis. Latreille.

*** Superior wings with two submarginal cells, the second receiving one recurrent nerve; two perfect discoidal cells, and one imperfect below: Four hinder tibiae with acute heels.

Tridens.

Sp. 4. Tridens.

Seclia tridens. Fabricius.

TRIBE IV. SAPPYIDAE.

Thorax with the first segment forming an arch, or a transverse square. Feet moderate, or short, slender, not strongly ciliated or spined. Antennae in both sexes as long as the head and the trunk. Superior wings with the marginal cell not remote; not folded longitudinally.

Apis. Linn.

VESPA. Geoffroy.

HELLUS. Fabricius, Panzer.

SPHEX. Villers.

Mandibles very strong, trigonate, many-toothed. Antennae thicker towards their extremities.

Serpunctatus.

Helius serpunctatus. Fabricius.

Inhabit Europe.

POLYCHRUM. Fabricius, Salzer, Latreille, Jurine, Donovan.

Mandibles very strong, trigonate, many-toothed. Antennae filiform.

Repandum.

Polychrum repandum. Spinolii, Latreille.

Genus DXCI. THYNUS. Fabricius, Salzer, Latreille, Jurine, Donovan.

Mandibles (of the males) narrow, bidentate, arcuate. Antennae slender, nearly setaceous.

Dentatus.

Sp. 1. Dentatus.

Inhabits New Holland.

TRIBE V. POMPILIDAE.

Thorax with the first segment forming an arch, or a transverse square. Feet long; the hinder ones as long as the head and trunk. Antenna slender, formed of elongate, and slightly serrated joints. Superior wings not folding longitudinally.

FAMILY I. POMPILIDAE.

Superior wings with three submarginal cells complete.

Genus DXCIII. PEPPIIS. Fabricius, Latreille.

POMPIIUS. Jurine, Illiger.

Palpi equally long; the two last joints of the maxillary ones, and the last of the labial ones, shorter than the rest.

Stellata.

Pepsis stellata. Fabricius, Latreille.

Genus DXCIV. POMPILUS. Latreille.

Maxillary palpi longer than the labial ones, with the last joint thicker, conico-ovate; the three last joints nearly equally long. Labrum inserted under the elytra. Antennae (of the females at least) with their joints convoluted.

Obs. This artificial genus contains the following genera, proposed by the most learned writers on the hymenopterous insects, viz. 1. Pompiulus, Fabr, Panzer, Jur. Illig, Walck. Spin. 2. Serex, Linn. Scop. Vill. Cuv, Laup. 3. ICHNEUMON, Geoff. 4. PESPIIS, Fabr. 5. SALIUS, Fabr. 6. CRYPTOCHILUS, Panzer. With the rejected genus 7. PSAMMOCHEILES of Latreille.

Pompiulus annulatus. Latr. Fabr.

Cryptocheilus annulatus. Panzer.

Sp. 2. Viaticus.

Sp. 3. Bicolor.

Salius bicolor. Fabricius.

Pompiulus bicolor. Latreille.

Sp. 4. Dispar.

Pompiulus dispar. Latreille.

Sp. 5. Planiceps.

Pompiulus planiceps. Latreille.

Spinoli.

Evania. Olivier, Villers, Rossi, Cuvier.

Maxillary palpi pendulous, longer than the maxillary ones; the three last joints equally long, the last joint thicker, conico-ovate. Labrum entirely exerted, entering to the anterior margin of the elytra. Antennae (in both sexes) thick, rigid, with the middle arcuated; not convoluted.

Ceropales maculata. Fabricius, Latreille.

FAMILY II. APHORIDA.

Superior wings with two complete submarginal cells.

Genus DXCVI. APORUS. Spinolii, Latreille.

Superior wings with the second submarginal cell receiving two recurrent nerves.

Aporus unicolor. Spinolii, Latreille.

TRIBE VI. SPHECIDAE.

Thorax with the first segment transverse linear. Feet long; the hinder ones as long as the head and trunk. Ocelli distinct. Superior wings not folding longitudinally.

FAMILY I. SPHECIDA.

Mandibles with their internal edge denticulated.

Genus DXCVII. AMPHILAE. Kirby, Latreille.

PESPIIS. Fabricius, Spinolii.

MISCA. Jurine.

Antennae inserted about the middle of the face. Maxilla and labrum much longer than the head, bent in the middle. Palpi very slender, with cylindrical joints.

a. Superior wings with the third submarginal cell not petiolated.

Sphex armata. Rossi.

Amophila armata. Latreille.
ENTOMOLOGY.

b. Superior wings with the third submarginal cell petiolated.

Antennae inserted at the mouth, (at the base of the clypeus?) Maxillary palpi filiform, longer than the labial palpi. Maxillae terminated by a lanceolate lobe. Lip with the intermediate division elongate.

** Family II. Belopæda. Mandibles without teeth on their internal edges.

Obs. The above four species are often confounded under the title of Sphex spiris of Linneus.

** Tribe VII. Bembecides. Thorax with the first segment transverse-linear. Feet short or moderately long. Labrum entirely exserted, very large. Ocelli very distinct. Superior wings not folded longitudinally.

Labrum elongate-triangular. Mandibles simply undentate on their internal edge. Maxillary palpi very short, four jointed. Superior wings with the marginal and the last submarginal cell almost meeting at their extremity, separated only by a very short angle.

Labrum elongate-triangular. Mandibles with two or three denticules on their internal edge. Maxillary palpi as long as the maxille, composed of six-joints. Superior wings with the marginal and last submarginal cells divided by a very distinct space.

** Tribe VIII. Labridae. Thorax with the first segment transverse-linear. Feet short or moderately long. Labrum entirely concealed, or but very obscure. Eyes elongate, reaching the hinder margin. Ocelli very distinct. Antennae inserted near the mouth; the first joint obovoid, or in-
ENTOMOLOGY.

Superior wings with the second submarginal cell petiolated.

Sp. 1. Flavipes.

Palarus flavipes. Latr.

Philanthus flavipes. Fabr.

Genus DCXII. Larra. Fabricius, Olivier, Jurine, 612. Larra.

Panzer, Spinola, Latreille.

Liris. Fabricius, Illiger.

SpheX. Villers, Rossi.

Antenna filiform. Superior wings with the third submarginal cell narrow, almost lunate. Mandibles without a tooth-like process on their internal edge.

Sp. 1. Ichneumoniformis.

Genus DCXII. Lyrops. Illiger, Latreille.

Tachytes. Panzer.

Larra. Fabricius, Jurine.

Liris. Fabr.

Andrena. Rossi.

Antenna filiform. Superior wings with the third submarginal cell narrow, almost lunate. Mandibles with a strong tooth on their internal edge.

Larra tricolor. Fabr.

Tachytes tricolor. Panzer.

Inhabits Germany.

Subdivision 2.

Superior wings with two submarginal cells.

Latreille.

SpheX. Schaeffer.

Pomphilus. Fabricius.

Crabro. Rossi.

Antenna, (of the males) moniliform, terminated by elongate, cylindric joints, convoluted in the middle. Mandibles acutely undentate on their internal edge.

Superior wings with the marginal cell appendiculated; the two submarginal cells sessile.

615. Miscophus.

Antenna with the joints alike in both sexes. Mandibles without distinct teeth. Superior wings with the second submarginal cell petiolated.

Inhabits France.

Division III.

Eyes notched.

616. Pison.

Tachybulus. Latreille's older works.

Alyson. Spinola.

Superior wings with three distinct submarginal cells.

Abdomen conic, with a very short, almost imperceptible peduncle.

Pison nigric. Latreille.

Alyson ater. Spinola.

Genus DCXVII. Trypoxylon. Latreille, Fabricius, Panzer, Illiger, Spinola.

Alyson. Jurine.

Superior wings with three submarginal perfect cells; the first distinct, receiving a recurrent nerve; the second obsolete, much smaller, receiving another ner-
Family I. Oxybellida.

Superior wings with one complete submarginal cell.

Genus DCXVIII. NITELLA. Latreille.

Antennae filiform nearly straight, longer than the head, the second and third joints nearly of equal length. Mandibles bidentate at their extremities. Tibiae not spinose. Tarsi with small pulvilli.

NITELLA Spinnus. Latreille.

Inhabits the south of France.

Genus DCXIX. OXYBELUS. Latreille, Fabricius.

Vespa. Linnéus, Illiger, Spinaola.

Sphex. Schaeffer.

CABRO. Olivier, Rossi.

Antennae thicker towards their extremities, longer than the head, convoluted, the second joint much shorter than the third. Mandibles without teeth at their extremities. Tibiae spinose. Tarsi with large pulvilli.

Sp. 1. Uniglaumis.
VEPSA Uniglaumis. Linn.

OXYBELUS uniglaumis. Fabricius, Latreille.

Inhabits Europe.

Tribe IX. CRABRONIDES.

Thorax with the first segment transverse-linear. Feet short, or moderately long. Labrum entirely concealed or but obscure. Eyes not reaching the hinder part of the head. Ocelli very distinct. Superior wings not folded longitudinally. Antennae inserted at the mouth with the first joint cylindrical or conic, or towards the middle of the face.

Family I. Crabronida.

Superior wings with one or two complete submarginal cells.

Division I.

Mandibles with their extremities bifid. Superior wings with but one recurrent nerve.

Genus DCXX. CRABRO. Fabricius, Olivier, Rossi, Jurine, Panzer, Illiger, Spinaola.

Sphex. Linnéus, Villers, Christus.

Vespa. Linnéus, Rossi, Harris.

Superior wings with all the submarginal cells sessile. Abdomen distinctly pedunculated. Tarsi terminated by a thick joint, bearing a large pulvillus.

Sp. 1. RUFICORNIS.
CRABRO RUFICORNIS. Fabricius, Jurine, Illiger, Spinaola.

Vespa. Linnéus, Villers, Christus.

Vespa. Linnéus, Rossi, Harris.

Superior wings with the second submarginal cell petiolated. Abdomen with a short peduncle. Tarsi with a small pulvillus.

Sp. 1. Lunicornis.
POMPIDUS L unicornis. Fabricius, Jurine, Panzer, Lute.

Division II.

Antennae thicker towards their extremities, inserted about the middle of the face. Clypeus trilobate.

Genus DCXXVI. CERCERIS. Latreille, Illiger, Spinaola.

Sphex. Schaeffer, Villers, Rossi.

Vespa. Geoffroy, Olivier, Harris.

PHILELANTHUS. Fabricius, Jurine, Panzer.

BEMEX. Rossi.

CRABRO. Rossi.

Antennae gradually thicker externally, very much approximating at their base, almost as long as the thorax, the third joint somewhat cylindrical. Mandibles with a tooth in their internal edge. Superior wings with the second submarginal cell petiolated.

Cerceris major. Spina, Latreille.
Philanthus quadricinctus. Fabricius, Panzer.
Inhabits Europe.

Vespa. Geoffroy, Villers.

Symex. Scharf.,

Crabro. Rossi.

Antennae distinct, abruptly thicker towards their extremities. Mandibles without any process in their internal edge. Superior wings with all the submarginal cells sessile.

Philanthus coronatus. Fabricius, Panzer, Latreille.
Inhabits Europe.

Tribe X. Vespides.

Superior wings folded longitudinally. Thorax, with the first segment forming an arc, prolonged behind even to the origin of the superior wings. Antennae twelve-jointed, with their extremities pointed. Lip with three glandiferous divisions, or with four long plumose setae.

Family I. Eumenida.

(Solitary wasps.)

Mandibles longer than broad, anteriorly meeting like a rostrum. Lip with the intermediate division narrow, and very long. Clypeus cordiform, with the point projected, and more or less truncated.

Division I.

Lip without glands at their extremity, divided into four very long linear and plumose divisions. Mandibles of the male very large.

Genus DCXXXI. Synagris. Latreille, Fabricius.

Vespa. Olivier, Jurine.

Palpi four-jointed; maxillary ones very short, labial ones longest. Abdomen ovate-conic, the two anterior segments not coarctate.

Synagris cornuta. Fabricius, Latreille.

Division II.

Lip having four glandular points at its extremity, parted into three pieces, the middle one large, and bifid or notched at its extremity.

Subdivision 1.

Superior wings doubled, three submarginal cells complete. Maxillary palpi six-jointed, not very much shorter than the labial ones.

Genus DCXXIX. Rycchium. Spinola.

Odynerus. Latreille.

Vespa. Fabricius.

Abdomen ovoid-conic, the first segment not, or scarcely, narrower than the second. Maxillary palpi, with the last joint scarcely longer than the terminal process of the maxillae; labial palpi smooth, the last joint distinct, the first evidently longer than the second. Maxillae with their process very long and narrow.

Rycchium Europeum. Spinola.
Vespa occulta. Fabricius.
Odynerus Europeus. Latreille.
Inhabits Europe.

Vol. IX. Part 1.

Odynerus. Latreille.

Vespa. Panzer.

Abdomen ovoid-conic. Labium very long. Maxillary palpi, with the last joint not extending beyond the extremity of the maxillae; labial palpi hairy, the fourth joint obtuse, scarcely visible. Maxillae with the terminal lobe narrow and long.

Pterochilus phaleratus. Klug.

Vespa phalerata. Panzer.

Odynerus phaleratus. Latreille.

Vespa. Panzer, Fabricius.

Abdomen ovoid-conic, the second segment broader than the first. Maxillary palpi, with two or three of the joints extending beyond the extremity of the maxillae. Maxillae with the terminal lobe short, short-lance shaped.

Vespa spinipes. Panzer, Fabricius.

Odynerus spinipes. Latreille.

Inhabits Europe.

Genus DCXXXII. Eumenes. Latreille, Fabricius.

Abdomen with the first segment contracted into an elongate peduncle, the second segment campanulated. Clypeus longitudinal, anteriorly produced into a point. Mandibles forming by their junction a long-pointed rostrum.

Eumenes coarctata. Fabricius, Latreille.

Inhabits Europe.

Genus DCXXXIII. Zethus. Fabricius, Latreille.

Clypeus as broad, or broader than long, without any remarkable production in front. Maxillary palpi shorter than the maxillae.

Zethus ceruleo-pennis. Latreille, Fabricius.

Genus DCXXXIV. Discus. Latreille.

Vespa. Panzer.

Clypeus as broad, or broader than long, without any remarkable protuberance before. Maxillary palpi longer than the maxillae.

Vespa zonalis. Panzer.

Discus zonalis. Latr.

Inhabits Europe.

Subdivision 2.

Superior wings extended, two submarginal cells complete. Maxillary palpi with less than six joints, shorter than the labial ones.

Genus DCXXXV. Ceramius. Latreille.

Sp. 1. Fonscolumbii.

Ceramius Fonscolumbii. Latreille.

Family II. Vespida.

(Social wasps.)

Mandibles longer than broad, long-quadrate, with their extremities obliquely truncated. Clypeus almost quadrate. Lip with the intermediate division a little lengthened, cordiform.

Genus DCXXXVI. Polistes. Latreille, Fabricius.

Vespa. Illiger, Spina, Jurine.

Vespa. Linneus, Geoffroy, Panzer, Jurine.

Mandibles (at least of the females and neuters) with their internal edge armed with three equal teeth, the
ENTOMOLOGY.

**Genus DCXL. Colletes.** Lateille, Illiger, Spinola, Klug.

**Apis.** Linnaeus, Olivier, Villers.

**Andrena.** Fabricius, Jurine.

**Hyloëus.** Cuvier.

**Evodia.** Panzer.

**Melitta.** a. Kirby.

Hinder feet pollenigerous. Superior wings with three submarginal cells. Antennae with the third joint longer than the second. Abdomen much elongated, more or less villose. Ocelli forming a curved line. Tongue obtuse, the apex bilobate.

The shape of the tongue is admirably adapted for the construction of its cells, which are described by the accurate Reaumur in the fifth memoir of his sixth volume, "don tene midls sont faits d'espees de membranes soyeuses."

According to this author, they make their nests in the earth that fills the cavities of certain stone walls. Some of them choose a northern aspect sheltered by trees. These nests are cylindrical, and consist of from two to four cells placed end to end, each of which is formed like a thimble, the end of one fitting into the other. The cells vary in size. The cylinder runs in a horizontal direction; but sometimes, from the intervention of a stone or of some other obstacle, it takes a different course, so that the last cell forms an angle with the first. The cells are composed of many layers of a very thin and transparent membrane, and the colour is generally reddish brown, which arises from the substance with which they are constructed. This is sometimes nearly liquid, at others it is merely a paste composed of pollen and honey. The larva, when hatched, very soon imbibes all that is liquid, and when full grown quite fills its cell. The substance with which they form their cells has not been ascertained, but Reaumur conjectures it to be a secretion from the insect.

**Succincta.**

Inhabits Europe.

**Sp. 2. Fodiens.**

**Colletes fodiens.** Latr.

**Melitta fodiens.** Kirby.

Inhabits Europe.

**Genus DCXLI. Prosopis.** Jurine, Fabricius, Illiger, Panzer, Spinola, Klug.

**Apis.** Linn. Geoff.

**Andrena.** Olivier.

**Bespa.** Rossi.

Hinder feet not pollenigerous. Superior wings with two submarginal cells. Antennae with the second and third joints nearly equally long. Abdomen conic, gibbous above. Tongue obtuse, the apex truncated, on each side auriculated. Ocelli placed in a triangle.

**Obs.** The insects of this genus, when pressed between the fingers, emit an agreeable odour.

**Family II.** Andrenida.

Lip with the intermediate process lanceolate, acute.

**Division I.**

Lip when at rest reflexed.

**Subdivision I.**

Superior wings with two submarginal cells.

**Genus DCXLII. Dasyphora.** Lateille, Fabricius, Illiger, Panzer, Illiger, Spinola, Klug.
Superior wings with three submarginal cells, the second small.

*Melitta.** c. Kirby.

Maxillae bent at their extremity, their terminal lobe scarcely longer than broad. Hinder feet, with the first joint of their tarsi shorter than the tibiae. Labium or lip little elongate, shorter than its palpi.

The species of this genus are extremely numerous, and a very large portion of them inhabit Britain. Their proboscis is downy and thick. The hinder legs of the male are furnished with a flosculus at their base, the tibiae with a thick scopar or brush, and their anus is covered by a fringe of hairs. They nidificate under ground in a light soil, some choosing banks over which bushes are scattered, others bare perpendicular sections, but all seem to prefer a southern aspect. They excavate burrows of a cylindric form, from five inches to nearly a foot or more in depth, of such a diameter only as to admit the insect. In making these holes, they remove the earth grain by grain, which they throw up on the outside of their holes in the form of a hillock. Some species penetrate in a horizontal, and others in a perpendicular direction. They construct a cell at the bottom of this hole, which they replenish with pollen made into a paste with honey, and in this they deposit their eggs. The pollen they carry in the scopar or brush of their hinder tibiae, upon the flosculus at the base of the hinder thighs, and on the hairs of the metathorax. When the female has committed her egg to the paste, she very carefully stops the mouth of her hole, to prevent the ingress of ants, or of other insects that might be enemies to the larvae.

Genus DCXLIV. *Ciliissa.* Leach's MSS.

*Melitta.** Kirby.

*Andrena.** Latreille, Panzer.

Maxillae bent near their middle, the terminal process very much longer than broad. Lip elongate, longer than its palpi. Superior wings with three submarginal cells, the second small.

This genus is not only distinguished from *Andrena* by the characters of the lip and maxillae, but also by having a longer tongue with very minute auricles, and the tops of the valves cultriform.

*Melitta tricincta.** Kirby.

*Andrena tricincta.* Latreille.

*Ciliissa tricincta.* Leach's MSS.

Inhabits England.

Sp. 2. *Hamorrhoidalis.*

*Andrena hamorrhoidalis.* Panzer.

*Melitta chrysa.** Kirby.

Inhabits Germany and England.

Division II.

Lip with the intermediate division incurved, or nearly straight. Superior wings in all with three complete submarginal cells.

Subdivision 1.

Lip with the intermediate division nearly straight, not twice the length of the head.

Genus DCXLV. *Sphecodes.* Latreille.

*Sphecodes.* Linnaeus, Villers, Rossi.

Apis. Geoffroy.

Proapis. De Geer.

Nomada. Fabricius.

*Andrena.* Olivier, Panzer, Jurine, Spinola.

*Dichroa.* Illiger, Klug.

*Melitta.** a. Kirby.

Labrum trigonate, of the male entire, of the female generally emarginate. Antennae of the males longer, almost moniliform, arcuased. Abdomen with the greater portion smooth.

The species of *Sphecodes* at first sight, bear a near resemblance to *Spex.* They make their nests in bare sections of banks exposed to the sun, and nearly vertical. According to Reaumur, they excavate to the depth of nine or ten inches, and deposit their eggs in a mass of pollen mixed with honey.

*Sphecodes gibbus.* Latreille.

Nomada gibba. Fabricius.

*Melitta gibba.* Kirby.

*Dichroa analis.* Illiger.

Inhabits Europe.

Subdivision 2.

Lip with the intermediate division incurved, longer than the lateral ones, and twice as long or more than the head.

*Hylæus.* Linnaeus, Villers, Rossi.

*Andrena.* Olivier, Panzer, Jurine, Spinola.

*Hylæus.* Fabricius, Illiger, Klug.

*Melitta.** b. Kirby.

*Halictus.* Latreille.

Lip lanceolate, little sericeous. Hinder feet in both sexes alike. Anus of the females with a longitudinal groove above.

The males of this genus are remarkable for an elongate cylindric body. The wings of many of the species are beautifully iridescent. They nidificate in bare banks.

*Hylæus sextincetus.* Fabricius.

*Halictus sextincetus.* Latreille.

Inhabits Europe.

Genus DCXLVII. *Nomia.* Latreille.

*Nomia.** Fabricius.

*Lasius.* Jurine, Panzer.

Lip very hairy, or tomentose. Hinder feet of the male with dilated incrassated tibia and thighs.

*Nomia diversipes.* Latreille.

*Megilla curvipes?* Fabricius.

Sp. 2. *Disformis.*

*Lasius disformis.* Jurine, Panzer.

Inhabits Germany.
TRIBE XIII. APhides.

Lip with the apex inflected, the intermediate labia filiform, and very long. Labial palpi, with the two first joints resembling a compressed seta.

FAMILY I. Panurgida.

(Solitary bees)

Hind legs with the first joint nearly equally broad, or gradually narrowing from the base to the apex, the second joint originating from the middle of its apex.

DIVISION I.

Palpi alike.

Genus DCXLVIII. Syfrophiia. Illiger, Klug.

Apis. Schaeffer, Rossi.

Eucera. Scopoli.

Andrena. Olivier.

Hylander. Fabricius.

Ceratina. Jurine.

Anthidiurn. Panzer.

Mandibles bidentate. Superior wings with three complete submarginal cells. Ocelli disposed in transverse straight lines. Antennae filiform, elongate; the apex convoluted in the males, of the females elongate-clavate, the apex acuminate.

Spiralis.

Syfrophiia spiralis. Illiger.

Andrena spiralis. Olivier.

Hylander spiralis. Fabricius.

Anthidiurn spiralis. Panzer.

Inhabits Europe.

Genus DCXLIX. Panurgus. Panzer, Spinola, Latr.

Apis. Scopoli.

Dasypoada. Illiger, Fabricius.

Erinops. Klug.

Mandibles not dentated. Antennae straight in both sexes, and subclavate. Superior wings with two submarginal cells. Ocelli disposed in a triangle.

Labatus.

Panurgus labatus. Panzer.

Dasypoada labata. Fabr.

Inhabits Europe.

DIVISION II.

Palpi unequal; the labial palpi setiform.

Subdivision 1.

Labrum nearly quadrate, transverse, or not much longer than broad. Mandibles tridentate at their points. (Superior wings with three submarginal cells).

Apis. Linn. Geoff. Vill. Rossi, Kirby. (** d. 2. a. b.).

Bombus. Fabr.

Centris. Fabr.

Labrum transverse, abruptly carinated transversely, the anterior margin ciliated, emarginated. Antennae filiform, with the scape very long. The wings of this genus are generally violet coloured, and composed of a substance between membrane and corium.

Violacea.

Apis violacea. Linn.

Inhabits Europe.

The following account of the economy of this species is extracted from Reaumur. "The mother bee usually makes her appearance in the spring, as soon as the winter is over; she may then be met with in gardens, visiting such walls as are covered with trees trained on trellis-work, in a sunny aspect. When once she has begun to make her appearance, she frequently returns, and for a long period may be known by her size, and her humming noise, which much resembles that of the genus Bombus. The object of these early visits is to fix upon a piece of wood calculated for her purposes. She generally selects the pertuscent supports of arbours, or vine-props, and will sometimes attack garden-seats, thick doors, and window-shutters; but she generally (if not always) selects a piece cylindrical and perpendicular. With her strong mandibles she bores into it, directing her course obliquely downwards, then proceeding in a direction parallel with its sides, till she has bored a cylindrical hole from twelve to fifteen inches in length, and seven or eight lines in diameter. Sometimes three or four tunnels are bored in the same piece, nearly parallel with each other. A passage is left where she enters, or first begins to bore, and another at the end of the pipe. As the industrious animal proceeds in her employment, she clears away the wood which she detaches, throwing it out upon the ground, where it appears like a small heap of saw-dust. Thus we see she has prepared a long cylinder in the midst of the wood, sheltered from the weather and from external injuries, and fitted for her purposes. She now enters to the bottom of the cylinder, and deposits an egg, and then lays in a store of pollen mixed with honey, sufficient for the nutriment of the larva when hatched. At the height of seven or eight lines, which is the depth of each cell, she next constructs, of particles of the saw-dust (formed in the boring of her tunnel) glued together, and also to the sides of the cylinder, an annular stage. When this is sufficiently hardened, its anterior edge affords a support for a second ring of the same materials; and thus the ceiling is gradually formed of these concentric circles, until a small orifice in the centre only remains; and this is also filled up with a circular mass of the agglutinated saw-dust. This partition exhibits the appearance of as many concentric circles as the animal has joinings; and is about the thickness of a French crown-piece. It serves for the ceiling of the lower, and floor of the upper apartment. One cell being completed, she proceeds to another, which she furnishes in the same manner; and so on, till she has divided her whole tunnel into apartments, which are usually about twelve. When the larva assumes the pupa, it is placed in its cell, with its head downwards, and is thus prevented, when it has attained its perfect state, and is eager to emerge into day, from disturbing the tenants of the upper cells, who, being of later date each than its superincumbent neighbour, are not quite so perf ected as to be ready to go forth upon the world."

Apis. Villers, Rossi, Kirby. (** d. 2. a.)

Prosopis. Fabr.

Pithitis. Klug.

Clavicaera. Walckenaer.

Labrum almost quadrate, perpendicular, entire. Antennae gradually thickening towards their extremities; the scape not large.

Apis cerulea. Villers.
Inhabitats Europe.

**Subdivision 2.**

Labrum longer than broad, inclined perpendicularly; is not rather beneath the mandibles, elongated, quadrato. Mandibles strong; proctored, with the apex bidentate, in some, trigonate, and often multidentate, in others.

* Labial palpi with the three joints continuous, the fourth inserted under the external apex of the third.

**Genus DCLII. Rophites.** Spinola, Latr.

Mandibles triangular. Maxillary palpi six-jointed.

**Genus DCLIII. Chelostoma.** Latr.

Apis. Linn. Villers, Kirby. (** c. 2. 7).

Hyleus. Fabr.

Anthophora. Illiger, Fabr.

Anthidium. Panzer.

Trachusa. Jurine.

Mandibles (of the females) arcuated, their apex bidentate or forked, with rather, internally hairy. Maxillary palpi three-jointed.

The bodies of the insects composing this genus are very long, slender, and cylindrical. The belly of the male, near the anus, is concave, and covered with down; and at its base is a horn or protuberance. When asleep, they roll themselves up like an armadillo, the horn or protuberance fitting into the anal cavity. They nidificate in posts and rails. The males usually repose in the centre of a flower.

Sp. 1. Florisomnias.

Apis florisomnias. Linn.

Chelostoma florisomnias. Latr.

Inhabitats Europe. The female is Apis maxilliosa of Linné and Kirby; Hyleus maxilliosus of Fabricius.

**Labial palpi with the third joint inserted obliquely on the external side of the second, near to the apex.**

**Genus DCLIV. Heriades.** Spinola, Latr.

Apis. Linn. Kirby. (** c. 2. 7).

Anthophora. Fabr. Illiger, Klug.

Anthidium. Panzer.

Trachusa. Jurine.

Labial palpi with the second joint longer than the first. Body very long, cylindrical.

This genus, in habit and in economy, resembles Chelostoma; the males are often taken asleep in flowers; their abdomen is then doubled, so that the tuhellece with which its base is armed fits into the cavity near the anus.

Sp. 1. Truncorum.

Heriades truncorum. Spinola, Latr.

Inhabitats Europe.

**Genus DCLI. Stellifer.** Panzer.

Apis. Kirby. (** c. 1. β).

Anthophora. Illiger.

Trachusa. Jurine.

Gyrodrom. Klug.

Labial palpi with the second joint not longer than the first. Maxillary palpi two-jointed; the first joint longest. Mandibles strong. Abdomen convex above, smooth below, and scarcely hirsute.

Stella aterrima. Panzer, Latreille.

Inhabitats Europe.

**Genus DCLI. Antidium.** Fabr. Panzer, Klug, Linn. Latreille.

Apis. Linn. Geoff. Schweffer, Kirby. (** c. 2. β.)

Anthophora. Illiger.

Megachile. Walckenaer, Spinola.

Trachusa. Jurine.

Labial palpi with their second joint not longer than the first. Maxillary palpi one-jointed. Abdomen of the females, below, very hairy; above, convex, incurved; the base broadly truncate. Mandibles broad, multidentate.

The anus of the males of this genus is always armed with spines.

Antidium manicatum. Panzer, Latreille.

Apis manicata. Kirby, Linn.

Inhabitats Europe.

The following interesting account of the economy of Antidium manicatum, is extracted from Kirby's *Monographia.* "Linnæus," says he, "observes, upon this bee, in *arboribus canis nidos construit;* but he takes no notice of the materials of which the nidi were made. This deficiency has been supplied by Mr James Trimmer and Sir Thomas Cullum: The former of these gentlemen some time since informed me, that having had frequent opportunities of watching the motions of Antidium manicatum, and finding that the female constantly attended *stackya germanica, agrostemma coronaria, and other woolly-leaved plants which grew in his garden, he was curious to know the reason of this preference. It was not long before his curiosity was gratified; and he discovered that it was the wool which covers the surface of the leaves of these plants, that was their attraction; for he observed the little animal, with her strong "mandibles," scraping it off with great industry and perseverance, and while these were thus employed, rolling it up, with her fore legs, into a little ball; making, all the time, a considerable hum. The use to which she applied the material thus collected, Mr Trimmer could never discover; we only conjectured that she employed it in the construction of her nest. Our conjecture is almost turned into certainty by the following account given by my ingenious friend Sir Thomas Cullum, to Mr Marsham, of a nest which he found made of similar materials. He thus expresses himself, in a letter to that gentleman. "I observed, in a lock of one of my garden gates, that the key did not turn easily round; and upon looking into the keyhole, I saw something white. I had the lock taken off; and it was completely full of a downy substance, containing the pupa of some bee; I conclude. Upon examining the downy substance, I am certain it is the fine pappus or down from the *Aemone sylvestris,* of which I had two plants in my garden. I have preserved the whole as I found it; but the bee has not yet made its appearance in its perfect state. I shall watch their progress, and send them to you or to Mr Kirby." This letter is dated October 10, 1800. Sir Thomas has since had the goodness to send me the nidi; the papes are still quiescent, (April 2, 1801), and will probably not be disclosed till after Midsummer. Upon comparing it with the anecdote which I have just related of this bee, I cannot help being of opinion, that it is the nidi of that species. It is with some hesitation that I venture to differ from so accurate an observer as Sir Thomas Cullum; but it appears to me that the wool which envelopes the nest and the cells, is scraped from the leaves of one of the first mentioned plants. I gather-
ENTOMOLOGY.

ed some leaves of *Agrostemma coronaria*, and with my penknife shaved off some of its down; and upon comparing it with that used in the nest, under a magnifier, I found that they were exactly the same. This, in conjunction with Mr. Trimmer's account, persuades me that the material employed in this instance is not the pappus of *Anemone arborescens*, which is of a more silky texture. There were several cells or cases included in the lock unconnected with each other, except by the wool which was their common covering. These cases were of an oval form, and consisted of an exterior coat of wool; under this was a membranaceous cell of a pale colour, which was covered with a number of vermiciform masses of a brown substance, seemingly made of pollen and honey, in shape and size much resembling *Spharia cannuculata*, and like that fungus distinguished by a longitudinal furrow slightly impressed. These were laid, without any regular order, over the cell, and by means of them the wool, which formed its exterior coat, was made to adhere. It is remarkable that this bee should employ these materials to cover its cells, which others use only as food for their larvae. At the summit of this membranaceous case is a small chimney, with an orifice; and within it contains another cell, which is rather coriaceous, strong, and of a brown colour, in the inside shining very much, as if covered with tinfoil. This may be the folliculus or cocoon made by the larva, previous to its assuming the pupa. I opened one of these in the autumn, and another in the spring. In both, the animal was still in its larval state, but had no food remaining in its cell. In that opened in the spring, it appeared to be dead. I imagine, when Sir Thomas Cullum first took them, that they were just ready for their first change; but that the alteration produced by removing the nest from the situation the parent insect had chosen for it, was fatal to some, if not all, of its inhabitants. Amongst the wool were masses of sweet pollen paste." He afterwards adds an extract from the Rev. Gilbert White's *Naturalist's Calendar*, (p. 109.) "There is a sort of wild bee frequenting the garden campion for the sake of its tormentum, which probably it turns to some purpose in the business of nidification. It is very pleasant to see with what address it strips off the pubes, running from the top to the bottom of a branch, and shaving it bare with all the dexterity of a hoop-shaver. When it has got a bundle almost as large as itself, it flies away, holding it secure between its chin and its fore legs."

**Genus DCLVIII. Osmia.** Panzer, Spinola. Latt. Apis. Linn. Villers, Kirby. (** c. 2. 2.**)

**Anthophora.** Fabricius, Illiger, Klug.

**Megaclile.** Waleknaer.

**Trachusa.** Jurine.

**Hoplitis.** Klug.

**Ambeys.** Klug.

Labial palpi with the second joint not longer than the first. Maxillary palpi four-jointed. Abdomen convex above, hairy beneath in the females. Mandibles broad.

**Coreutaces.**

**Osma cornuta.** Latreille.

**Osma bicarinata.** Panzer?

**Apis bicarum.** Kirby?

Inhabits Europe.

This species selects the hollows of large stones for the purpose of nidification.

**Sp. 1.** Cornula.

**Sp. 2.** Coreutacea.

**Coreutus.** Kirby, Linn. Apis cornuta. Linn.

**Coreutus.** Kirby, Linn.

Inhabits Europe, constructing its nest of argillaceous earth mixed with chalk, upon stone walls. Mr. Kirby supposes that it nidificates also in chalk pits.

**Genus DCLVIII. Meaclile.** Latr. Walek. Spin. Apis. Linn. Villers, Kirby. (** c. 2. a.**)

**Anthophora.** Fabr. Illiger, Panzer, Klug.

**Trachusa.** Jurine.

**Xylocopa.** Fabricius.

**Centris.** Fabricius.

Labial palpi with the second joint not longer than the first. Maxillary palpi two-jointed, the first rather longest. Mandibles very strong. Abdomen triangular, flat above, very downy beneath in the females.

The insects of this genus are well known by the name of *Leaf-cutters, Carpenter-bees*, and *Coupéuses de feuilles*; their interesting economy having attracted the attention of many naturalists. So early as 1670, it was noticed by Ray, Dr. Lister, Willoughby, and Sir Edward King. Linnaeus in this, as in many other instances, (supposing the economy of a genus to be peculiar to one species only,) has confounded several species under the general title of *Apis centuncularis*, and denoted it by the orange-coloured hairs which cover the under side of the abdomen, a character which it possesses along with a great number of species.

Some of the species nidificate in trees, and others beneath the ground. The following history of the economy of the genus, (and which will apply to all with which we are acquainted,) is given by Reaumur. "The nests they construct are cylindrical, sometimes six inches in length, and composed entirely of the leaves of trees. They usually consist of several cells, each of which is shaped like a thimble, the convex end of the second fitting closely into the open end of the first, the third into the second, and so on with respect to the rest. Although these cells are honey-tight, which is often found within them in a liquid state, yet the portions of the leaves are not glued together, but merely most accurately adjusted to each other. In forming the cell, the pieces of leaf are made to lap over one another, so that the natural margin of the leaf is kept on the outside, and that which has been cut within; thus a tube is first formed, and in this way coated with three or four layers, the exterior covering being made of larger pieces than the interior. In coating, the provident insect is very careful to lay the middle of each leaf over the margins of those that form the first tube; thus the sutures are covered and strengthened. At the closed end, or narrow extremity of the cell, the leaves have a bend given to them, so as to form a convex termination; when a cell is formed in this manner, her next care is to fill it with pollen and honey. When it is nearly filled, she deposits an egg, and closes it with three pieces of leaf," (sometimes with more,) "which are so exactly circular, that a pair of compasses could not define their margin more truly; and these coincide most accurately with the sides of the cell, and are retained in their situation by no gluten, but by the accuracy of their adaptation alone. After this covering is fitted in, there remains still a concavity which receives the convex end of the succeeding cell. In this manner, the patient and indefatigable little animal proceeds, till she has completed her cylinder of six or seven cells. This cylinder is coated externally by other pieces of leaf of larger dimensions than those used in making the cells, and of a different form, for they are nearly oval; those at the ends are bent inward, to cover each extremity. These nests are usually made in fistular passages, which these indefatigable creatures bore under ground in a horizontal direction;
their diameter is exactly that of the cylinder, to which indeed, they give its form, and their bend to the pieces which compose it. If by any accident their labour is interrupted, or their edifice deranged, it is astonishing with what persevering patience they set themselves to put all things again in order. Their mode of cutting the leaf, too, requires particular notice. Nothing can be more expeditious; they are not longer about it than we should be with scissors. When the insect has selected a bush furnishing the leaves required, she keeps hovering over and flying round it, until she has discovered the leaf best adapted for her purpose. When she has chosen the leaf, she alights on it, sometimes on the upper surface, sometimes underneath it, or at other times on its edge, so that the margin passes between her legs. As soon as she has made a beginning; (which she usually does near the main nerve,) she continues cutting with her mandibles, until the work be completed. As she proceeds, she keeps the margin of the detached part between her legs, those on one side being above, and the other below it, so that the section keeps yielding to her, and does not interrupt her progress. She makes her incision in a curve line, approaching the rachis at first; but when she has reached a certain point, she keeps receding from it towards the margin, still cutting in a curve. When she has nearly detached the portion she has been employed upon from the leaf, she balances herself, lest its weight should carry her to the ground; and the moment of its parting from the parent stock, she flies off, the detached portion remaining bent between her legs, and being perpendicular to her body. She pursues the same mode, whatever the form or size of the piece necessary for her purpose. The larvae when arrived at full size, spin a cocoon thick and solid of silk, which they attach to the sides of the cell. 

Mr Kirby very justly supposes resumur to be mistaken with respect to the mode of forming their cylindric nests. He considers that the nest takes its form, and the leaves composing it their bend from the passage, and that the external cost must be first deposited, as the insect could not get between the side of the cylinder and of the nest.

**Genus DCLXI. AMMOCITES. Lateire.**

Maxillary palpi six-jointed. Superior wings with two submarginal cells complete.

*Apis DCLXI. Ammocites. Latreille.*

Maxillary palpi two-jointed. Superior wing with two submarginal cells.

*Apis DCLXI. Rufiventris. Latreille.*

Maxillary palpi four-jointed. Superior wings with two submarginal cells.

*Apis DCLXI. Punctatus. Fabricius.*

Maxillary palpi two-jointed. Superior wings with two submarginal cells.

*Apis DCLXI. Punctatus. Fabricius.*

Metabola.

**Subdivision 3.**

Labrum remarkably longer than broad, inclining perpendicularly to the mandibles, triangulate, truncate. Mandibles narrow, pointed, unidentate on their internal edge. Body simply pubescent. Superior wings with two submarginal cells complete.

**Subdivision 4.**

Labrum a little broader than long, subsemicircular or semi-oval. Mandibles slender, pointed, unidentate on their internal edge. Abdomen not pollenigerous. Superior wings with three submarginal cells complete. Maxillary palpi six-jointed.

**Genus DCLXII. Nomada. Scop. Fabr. Illiger.**

Superior wings with three complete submarginal cells. Maxillary palpi one-jointed.

Superior wings with two complete submarginal cells. Maxillary palpi two-jointed.

Superior wings with two complete submarginal cells. Maxillary palpi four-jointed.

Maxillary palpi with more than four joints. Lip with its lateral divisions as long or longer than the labial palpi. Antennae of the males very long.

** Lateral divisions of the lip almost as long as the palpi. Body very villose in parts. Scutellum spinose. Superior wings with three submarginal cells.

** Lateral divisions of the lip almost as long as the palpi. Body very villose in parts. Scutellum spinose. Superior wings with three submarginal cells.

Maxillary palpi six-jointed. Labial palpi filiform.

Maxillary palpi one-jointed, very short.

Maxillary palpi three-jointed.

Crocisa. Jurine. Symmorpha. Klug. Maxillary palpi six-jointed, with five very distinct. The insects of this genus are supposed to be parasitical.

Crocisa. Jurine. Symmorpha. Klug. Maxillary palpi six-jointed, with five very distinct. The insects of this genus are supposed to be parasitical.

Family II. Apida.

Lip with the apex generally hirsute, not inflected.

Division I.

Hinder feet of the females, with their tibiae externally, and the first joint of the tarsi very hairy.

Subdivision 1.

Maxillary palpi with more than four joints. Lip with its lateral divisions as long or longer than the labial palpi. Antennae of the males very long.

Maxillary palpi distinctly six-jointed. Superior wings with two submarginal cells, complete.

Genus DCLXIX. MACROCERA. Latreille.

Eucera. Panzer. Maxillary palpi distinctly five-jointed, the sixth joint very obsolete, or wanting. Superior wings with three submarginal cells complete.

Subdivision 2.

Maxillary palpi with four joints or more. Lip with the lateral divisions shorter than the palpi. Superior wings with three submarginal cells complete.

* Labial and Maxillary palpi alike.

** Labial palpi setiform.

Apis. Linn. Geoff. Kirby, (**) d. 2. a.

Genus DCLXXII. SAROPODA. Latreille.

Genus DCLXXIII. CENTRIS. Fabricius.

Subdivision 3.

Maxillary palpi one-jointed.

Division II.

Hinder feet with the tibia and first joint of the tarsi shortly hairy. (Social bees.)

Subdivision 1.

Hinder tibiae terminated by two spurs or heels. Superior wings with three submarginal cells in all, complete, the last neither linear nor oblique.

ENTOMOLOGY.

TRIBE IX. Anthracidae.
Body short. Wings divericating. Antennae distant, three-jointed. Head as high as the thorax.

TRIBE X. Bombilides.

TRIBE XI. Acroceridae.
Body short, as if inflated. Wings divericating. Antennae three or two-jointed.
6. Proboscis (when at rest) retractile within the cavity of the mouth.

TRIBE XII. Syrphidae.
B. Has terminal with two setae.

TRIBE XIII. Conopidae.
Proboscis prominent, nearly clyclic or conic, without any remarkable dilatation.

**Index.**
the built, ladies, the curtain full and of that Senhora of Villanova, of Porto, and of Villar de Veiga.

The valley of Villanova is extremely beautiful. Small fields of maize, even of rye and barley, and rarely of wheat, are encircled with lofty oaks, chestnuts, and poplars, every tree supporting a vine, which spreads over its summit, and often reaches the top even of the highest oak. The fields are watered by artificial brooks, which communicate an agreeable freshness to the air even in summer.

Arid mountains, covered with heath, separate the valley of Villanova from that of Braga. The city of Braga, of which we have already given a full description in that article, is situated in a broad open vale, shaded by trees, and well cultivated, and abounding with cork trees.

The valley of Porto de Porto, where there is a stone bridge over the Cavado, and a village of the same name, is about a league from Braga. This valley is extremely beautiful, appearing like a thick wood of high trees, though the houses, fields, and gardens, are embosomed among the trees. At the distance of two leagues from that valley, and at the foot of the mountain, stands the rich and extensive Bernardine monastery of Bouro, situated about 500 feet above the level of the sea. On a mountain, at a great distance, is the church of Nossa Senhora de Abadia, where there is a miraculous figure of the Virgin, which is visited by numerous pilgrims.

Into the valley of Villar de Veiga, which is the name of a large village, the rapid stream of the Rio das Caldas pours itself over rugged rocks; and, after climbing the mountains for about a league, the traveller reaches the village of Caldas de Gerez, celebrated for its warm baths. The valley is here extremely narrow. To the eastward, the houses lean against the rocks, a stream waters them to the west, and also the foot of another mountain. The valley to the northward rises rapidly up the heights; and an eminence to the southward, before it descends, incloses this dell. The mountains are steep, lofty, and rocky, trees being found chiefly on the banks of the river, consisting of oaks, berry bearing alders, aceiros, and olives. The mountains are covered with thick bushes, especially along the brooks, and consist of strawberry trees, erica arborea, aceiros, and two new varieties of cytisus, which render the mountains impassable. Single oaks of a remarkable kind, grow on the highest summits.

The village of Caldas de Gerez consists of 40 stone houses, which are ill built, and have but one story. The apartments are small and inconvenient, the windows have in general no glass, and the floors are so bad that one can see through them. Their only furniture consists of a rough wooden table and coarse chairs. A small square, about 200 paces in length, serves as the promenade; but there is no place where the company can ride; ladies, and feeble patients, being carried in litters borne by two horses. The warm springs rise to the eastward from a wall of granite rock, at the foot of a high mountain. They are four in number, and over each a square house is built, in the middle of which is a bath walled round. One person only can bathe at a time; and a curtain is the only screen for protecting the bathers from view. One of the springs contains hepatic gas. The heat of the warmest does not exceed 40° of Reaumur; and the hottest may be used as a bath. The bathing season continues from June till August.

The company, which consists of a part of the English from Porto, and of the inhabitants of the small towns of the Minho, rise at four in the morning, bathe or drink the waters immediately, and then walk till near seven. They dine at 12, and then take a long sleep; at four they again bathe or drink the water; after sunset they take a second walk, and, after assembling at a tea or card party, they sup at 10.

The mountains of Serra de Gerez, which separate this province from Spain, extend in general from east to west, but send out many arms to the south. The valley where Caldas lies, stretches in the same direction, rising continually to the north, till it again sinks towards the frontiers of Galicia, which are only three leagues distant from Caldas. The valley rapidly narrows, becomes more woody and rocky, till the traveller enters a thick shade of lofty oaks. Lofty walls of rugged rocks now appear, and the mountain assumes an appearance of sublimity. Near Galicia, the river homen intersects the valley obliquely, and flows into another. In this place are the ruins of a Roman bridge and a Roman road, which the mountain torrents have in vain endeavoured to destroy. From this spot a narrow footpath leads into Spain, which commences in a pass called Portela de Homem. The highest of the mountains of Gerez is to the eastward of Caldas, towards Montalère; the highest peak, which is between 3000 and 4000 feet high, is named O Muero de Burrageiro, and consists of rocks heaped together. The view to the west is extensive, commanding the greater part of the province of Minho and the sea. The horizon in other quarters is bounded by mountains. The granite of which this range of mountains consists, often contains bary salt, and, in the clefts, mountain-crystals and smoke topazes, and sometimes a fine rose-coloured quartz. The flora consists of Biscayan and Pyrenean plants, and of several nondescript species. Wolves are here so numerous, as to render this range dangerous for travellers. The Caucasian goat abounds here; it is found in the northern part of the peninsula: its flesh is much esteemed; the skin is used as covers for mules, and the horns for household ornaments. Great numbers of lizards and snakes abound in this range; these are generally the Lacerta agilis of Linnaeus, and the Vipera Roti.

Between Caldas and the village of Covide, appear the remains of an old mountain fort, which the inhabitants affirm are the ruins of an old city called Chalecodon. No inscription occurs among these ruins.

The chief towns of this province are Braga, Porto, Viana, Ambante, Guimaraes, Ponte de Lima, and Pe
174

EPA

so de Regina. The principal rivers are, the Minho, the Douro, the Lima, the Neiva, the Cavado, the Ave, &c., all of which run westward into the Atlantic.

The province contains three cities, 25 towns, 223,495 houses, and 900,000 inhabitants. (w) ENYDRA, a genus of plants of the class Syngeneia, and order Polygama Segregata. See Botany, p. 512.

EPACRIS, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 141, 170.

EPAMINONDAS, a celebrated Grecian general, was born at Thebes in Boeotia; and was descended, by his father Polyommis, from the ancient sovereigns of his country. He was educated in his father's house, along with Philip of Macedonia, under the Pythagorean philosopher Lysis; and, from an early age, devoted himself to the study of philosophy. Nor was he inattentive to the more ornamental accomplishments; and particularly applied himself to those athletic exercises, which at that time formed the chief amusement of the Greek youth. While he was distinguished by the most amiable dispositions, and mingled freely with young persons of his own age, he was remarkably reserved in his manners. He spoke seldom, even to his intimate friends; but the few words which he occasionally uttered were so uniformly pertinent and judicious, that, when he was only 15 years of age, it was said of him by Spintarus of Tarentum; “I never knew a man who understood so much, and spoke so little. Though thus accomplished and admired, he was one of the poorest citizens of Thebes; and no solicitations of his friends could ever prevail upon him to accept of riches, or to alter his frugal mode of life. Anxious to correct the luxurious manners of his countrymen, and to inspire them with that virtuous spirit, which might enable them to maintain their public liberties, he omitted no opportunity of resisting their dissipated habits; and, when once questioned, at a public festival, why he had appeared in so plain a dress, and with so pensive an air, he replied, “For I wish, that one person may remain to watch over the safety of the city, when you are all drowned in wine and debauchery.” Having attracted the esteem and affection of Pelopidas, one of the wealthiest and most illustrious of the Thebans, he inspired his friend with similar sentiments; and, by their united influence and example, they revived among their fellow citizens that love of sobriety and virtue, which laid the firm foundation of their future eminence. These two friends, having been appointed to join the troops, which were sent to the assistance of the Lacedemonians, in the war against the Arcadians, gave the first signal proof of their own military spirit, and raised the character of their country among the neighbouring states. At the battle of Mantinea, they sustained with heroic courage the hottest of the fight, and Pelopidas, having fallen covered with wounds upon heaps of slain, the desperate exertions of Epaminondas for his rescue, restored the victory to the routed Lacedemonians. When the Spartans, a few years afterwards, jealous of the rising power of the Thebans, had treacherously made them believe themselves masters of their city, and when Pelopidas, with the other exiles, had formed a scheme for the liberation of their country, Epaminondas, whose obscure station and love of study had saved him from banishment, privately seconded the enterprise with the utmost sagacity, and after the execution of the plot, openly appeared among the asserters of the independence of Thebes. Sacrificing his love of retirement and philosophy to the interests of his country, he came forward with his friends to share all the burdens of government, and the dangers of war. By their prudence, vigilance, and activity, they baffled all the exertions of the renowned Agesilaus in several campaigns; prevented him from gaining any other advantage than that of laying waste their country; and gradually taught the Theban soldiers to face, and even to vanquish, on equal terms, their hitherto triumphant invaders. Aratus, the Persian monarch, having convoked an assembly of the Grecian states at Sparta, for the purpose of accomplishing a general pacification, Epaminondas was placed at the head of the Theban deputation. Here, while the other deputies were overshadowed by the haughty Agesilaus, he alone asserted the independence of his country, and recommended a general resistance to the overgrown power of the Lacedemonians. The Spartan king excluded the Thebans from the league, and war was declared against them as the enemies of Greece. Epaminondas was unanimously chosen to conduct the affairs of Thebes; and, having selected six of the principal citizens as his associates, to whom he gave the appellation of Bootarchs, or governors of Boeotia, he marched with 6000 infantry and a small body of cavalry, to oppose the Lacedemonian king, Cleombrotus, at the head of 10,000 foot and 1000 horse. The hostile armies met at Leuctra, a small town in Boeotia, B.C. 371. Epaminondas, by the courage with which he inspired his troops, and the new plan of attack which he adopted, gained a complete victory over double his numbers; and cut off the Spartan commander with the flower of his army. The victorious chief rejoiced in the exaltation of his country; but declared that his highest personal gratification consisted in having acquired so great glory while his parents were alive. Two years after this memorable success, he entered the territories of the Lacedemonians, where, for the space of 600 years, an enemy's camp had never been pitched; and, at the head of 70,000 troops from different states, overran all Laconia with fire and sword, and advanced to the very walls of Sparta, which on one occasion he had in his power to destroy; laid waste its suburbs in the sight of its kings, and, having completely humbled that formidable power in the sight of all Greece, returned to Thebes with an army crowned with victory, and loaded with the spoils of the enemy. Entering his native city, which he had raised from the lowest humiliation to the height of political greatness, he found a factious party prepared to accuse him and his colleague of treason against the state, for having retained their office as Bootarchs four months beyond the term prescribed by law. An assembly of the ungrateful people was ready to condemn the two friends to capital punishment, when Epaminondas, anxious to save the life of Pelopidas, acknowledged the breach of the law which he had committed, and took upon himself the whole of the guilt in having advised the measure; “The law condemns me,” he exclaimed before his judges, “and I consent, if it must be so, to suffer as an example; but permit me to make this single request. I suffer for having led you into Laconia, where no enemy before you had dared to proceed; I suffer for having carried into their towns and territories, the desolations which they first brought upon our miserable country; I suffer for gaining your victories and enlarging your power. Behold the crimes for which I am condemned! let them be engraved upon my tomb, that, when posterity shall hear of my punishment, they may also be informed of the cause.” This speech
was received with shouts of applause, and the judge pronounced a sentence of acquittal. Epaminondas, stripped of authority, returned without a murmur to the station of a humble citizen; and when, a few years afterwards, an army was sent against Alexander the tyrant of Pherae, he enrolled himself to serve as a common soldier. In that capacity he saved the army from destruction, and was instantly, by the unanimous voice of the soldiers and citizens, reinstated in the command. During the intervals of peace, he laboured to introduce order and integrity into the management of the public finances; and, in his enlarged views of policy, he adopted the most effectual plans for rendering his country as powerful by sea as it was by land. He persuaded the people to vote a large sum for building a fleet; and succeeded in gaining possession of the maritime stations at Rhodes and Chios. But the growing power of Thebes having excited the jealousy of the other states, he was called to make head against a formidable confederacy of the Mantinians, Athenians, and Lacedemonians. With his usual promptitude in warlike expedi tions, he made a sudden attempt upon the city of Sparta; but, after having penetrated to the Kom, he was compelled to retreat by the desperate resistance of Agesilaus and his son Archidamus. He then hastened to make a similar attack upon Mantinea; but, contrary to his calculations, found it prepared against a surprise. Anxious to retrieve his own fame, and to raise the courage of his army, which had suffered some depression by the failures of these enterprises, he determined to risk a general engagement. He had an army of 30,000 infantry and 3000 cavalry, while the united forces of the Lacedemonians and of their allies did not exceed 20,000 foot and 2000 horse. But, though superior in numbers, he omitted no advantage which it was possible to derive from military skill; and never exerted his talents more than on this occasion, to deceive and to disconcert the enemy by his manoeuvres. His order of battle is considered as the most simple and best concerted, that has been recorded in the annals of ancient tactics. Pretending to pass the Lacedemonians, as if upon a march, he suddenly formed his line of attack, charged their centre with a strong column in an oblique direction, and routed their main body with immense slaughter. To gain a complete victory, he had only to collect his Thebans, and fall upon the wings of the enemy, which were ready to give way; but hurried along by his desire of victory, and his inveteracy against the enemy, he advanced almost alone into the midst of the fugitives. Recovering from their panic, they assailed him, with the utmost fury, overwhelmed him with a shower of darts, and one of them at length plunged a lance into his breast, the iron head of which, broken off by the force of the blow, was left in his body. Carried to his tent, he heard without emotion the declaration of the surgeons, that his wound was mortal, and that his death must follow the extraction of the weapon. He first asked his attendants if his buckler had been saved; and when it was brought, he clapped it to his breast as the companion of his exploits. He next inquired concerning the event of the battle; and, having been informed that the Thebans were victorious, he exclaimed, "it is enough; I die unconquered; advise my countrymen to conclude a peace!" One of his intimate friends, lamenting his death, and his want of any offspring to revive his name; "you mistake," he replied, "I leave behind me two immortal daughters, the victory of Leuctra, and that of Mantinea." Having said this, he directed the iron to be extracted, and instantly expired, B.C. 363. The glory of his country perished along with him, and his distinguishing greatness consists in this, that he inspired an obscure and oppressed people with his own exalted sentiments. He has justly been regarded as one of the most distinguished characters that any age or nation has ever produced; and was equally eminent as a philosopher, a statesman, a commander, and a virtuous citizen. **EPHEUSIS.** A celebrated city of Ionia, and once the metropolis of Asia Minor, is affirmed by Pliny, Justin, and Orosius, to have been built by an Amazon, whose name also it is supposed to bear. It was then possessed by the Carians and Leleges; but was occupied by Androcles, the son of Codrus king of Athens, who conducted the first colony of Ionians into Asia. This prince and his immediate descendants continued, during several generations, to exercise the regal power in the new colony; but afterwards, a change of the name, of the date and the occasion are unknown, took place in the form of government; and the city remained under the administration of a senate, till the time of the tyrant Pythagoras, who usurped the sovereign power, and who flourished before the birth of Cyrus the Great.

Under his successor Pindarus, who ruled with an authority equally absolute but with greater moderation, Ephesus was besieged by Croesus king of Lydia, who, from respect to the tutelary goddess of the place, restored to the citizens their former liberty, and conferred upon them numerous marks of his favour. Pindaros, who, according to Elian, was the nephew of Croesus, being obliged to resign his power, retired to Peloponnesus; but the city, which was successively subject to the Persians and to the Grecian states, seems to have again fallen under the dominion of tyrants. Of these, history has mentioned Athenagoras, Comas, Aristarchus, and Hegesias, the last of whom was expelled by Alexander, when he defeated the Persians on the banks of the Granicus, and a democracy established in the city. After his death it passed into the hands of several of his successors, and particularly of Lysimachus, who caused the ancient city to be destroyed, and, built a new town in a more commodious situation, and nearer to the temple of Diana, which was about seven stadia from the walls of the former. From this period the Ephesians were subject to the kings of Syria, till the Romans, when they gave liberty to the Greek states, in Europe, extended the same privileges to the Greek colonies in Asia. Reinstated in their ancient rights, they became the allies of Rome; but were afterwards persuaded by Mithridates of Pontus to take part with him against their protectors, and even to massacre, without distinction, all the Roman citizens within their gates. For this barbarity they were severely punished by the victorious Sylla, who suffered his soldiers to live upon them at discretion, and almost reduced them to beggary by the heavy contributions which he imposed; but by the favour which they experienced from the future emperors of Rome, they regained, in a great measure, their former splendour, and enjoyed for many years...
years some show of liberty. The city suffered severely from the earthquake, which desolated the principal cities of Asia in the reign of Tiberius; but was completely repaired by that emperor, and ornamented with many magnificent edifices. The games, originally instituted in honour of Diana, appear to have been much attended so late as the reign of Caracalla. It is celebrated as having been the seat of the most flourishing of the first Christian churches, where the apostle Paul preached for three years, where the evangelist John resided during the latter part of his life, and where Timothy was the first bishop. Under the auspices of Constantine and Theodosius, the Christian faith made rapid progress, and numerous churches were erected on the ruins of the Pagan temples. Under the reign of the emperor Alexis, the father of Anna de Comnena, it first fell under the power of the Saracens, from whom it was retaken by the Greeks in 1206, but was again lost in 1222, and from the commencement of the 14th century has formed a part of the Turkish dominions. Long before the extinction of the Greek empire, Ephesus had fallen into general decay; and a new town and citadel having been founded at Aiassoluk or Ajasuluk, about two miles distant, the ancient city was soon totally deserted.

Ephesus was known in ancient times by a variety of names, Alopea, Ortygia, Morges, Smyrna, Trachaea, Samornion, and Tela; and is described by ancient geographers as at once the ornament of Asia, and the most frequented emporium of that continent. Its citizens, in addition to their mercantile eminence, were liberal patrons of the fine arts, and their temples possessed many of the most celebrated productions of ancient genius. Their architecture was conducted principally by Phrasex, whom Vitruvius mentions with much commendation. Agesilaus the son of Dosotheus was one of the most eminent sculptors. Partheus, Apelles, and Euphorus, (the master of the latter,) all holding the first rank as painters, were natives of Ephesus. Artemidorus the historian and geographer, and Heracleitus the melancholy philosopher, were also born within its walls. The Ephesians were equally noted for their luxurious and licentious manners; and are said to have banished one Hermolodus solely on account of his virtue. (See Dr. Goodwin's Works, vol. i. p. 7.) They were much addicted to superstition, sorcery, and magical arts; whence arose the proverbial expression, "Ephesian letters," to denote those spells or sentences, which they used to write upon their girdles, or to imprint upon different parts of their bodies, as charms against evil, or as sources of supernatural power.

But the great boast of the Ephesians, and the principal ornament of their city, was the celebrated temple of their tutelary goddess Diana. The original object of their worship was a small statue of chry or ebony, made by one Canitis, though commonly believed in those days to have been sent down from heaven by Jupiter; but, what is more remarkable, it had no resemblance to the elegant huntress Diana, and was merely an Egyptian head with a many-breasted, representing the goddess of Nature. As the original figure became disfigured by extreme age, it was propped by two rods of iron like spears, which, even after its renewal, were religiously adopted in the substitute. It was at first placed upon a block of beach or elm wood, but in later times was preserved in a shrine adorned with all that wealth and genius could contribute. As the veneration for the goddess increased among the inhabitants of Asia, a magnificent temple was constructed on the spot where the elm had stood, and the sacred image placed within it. This temple seems to have been several times (Pliny says seven times, lib. xvi. c. 40.) ruined and rebuilt, a circumstance which may help to reconcile the discrepancies which occur in ancient writers, as to the dates and descriptions of these successive erections. One of them is expressly affirmed by Livy (lib. i. c. 45.) to have been completed in the reign of Servius Tullius, who flourished at the latest 570 years before Christ. Another is described which was originally designed by Ctesiphon, a Chilian architect, 541 years before the Christian era, whose plan was continued by Dnecrtius, a priest of Diana, and the whole at length completed by Daphnis of Mileus, and a citizen of Ephesus. This temple is said to have been partially destroyed by fire on the day when Socrates was poisoned, 400 years B.C. and again 356 B. C. by the philosopher Herostratus, on the day when Alexander the Great was born. Diana says Timaeus the historian, being then absent at the delivery of Olympia. The incendiary confessed, upon being put to the torture, that his only motive for the sacrilegious act, was a desire to immortalize his name; and though an assembly of the Ionian states passed a decree condemning his name to oblivion, the prohibition served only the more to perpetuate its remembrance. According to some accounts, nothing but the four walls and a few columns escaped the fury of the flames; while others relate, with greater probability, that only the roof, and some other parts constructed of timber, were destroyed. The Ephesians had begun its reparation, when Alexander, in his expedition against the Persians, offered to appropriate his spoils to the completion of the work, upon condition that his name should be inscribed, as its restorer, upon the front of the edifice. This proposal they accounted it disgraceful for them to accept; but secured the forgiveness of the conqueror by the flattering style in which his refusal was conveyed: "It is not suitable for one divinity," said the Ephesian deputy, "to decorate the temple of another." The women of Ephesus, besides working at the materials intended for its ornament, devoted their jewels to its restoration; and all Asia contributed to its progress. Cheiraroplastes, who assisted in building Alexandria, and who had proposed to cut Mount Athos into a statue of Alexander, was the architect employed at its commencement; but 220 years (says Pliny, lib. xxvii. c. 14.) or even 400 years (says the same author, lib. xvi. c. 40.) were spent in completing the building. It is difficult to determine whether the description of the temple given by this writer applies to its appearance prior or posterior to the conflagration in 356; and it is impossible to make it in any measure intelligible, except by supposing, with the Marquis de Poleni, that its dimensions were exactly the same both before and after the time of Herostratus, and that it was merely restored, though with greater magnificence and taste, to its former state. It was built on a marshy spot, that it might be more secure from the effects of earthquakes; and under its foundations was laid a bed of charcoal firmly rammed, and above that another of wood. The whole building was 425 feet in length, and 220 in breadth, supported by 127 pillars of Parian marble, and of the Ionic order, each 60 feet high. Those pillars were furnished by so many princes, and 36 of them were curiously carved by Scopas, while the rest were finely polished. Along the flanks of the cell was a double row of columns, 15 on each side. It is considered as the first instance in which, according to the Ionic style, the fluted column and
capital with volutes were introduced; it is calculated that each pillar, with its capital and base, contained 150 tons of marble. The doors and panelling were made of Cypress wood, polished and shining; and the stair-case of vine wood. Its internal decorations were heightened by the lustre of gold, and especially by the most perfect productions of the artists of antiquity. It contained a statue of Hebe, by Scopas; a picture of the goddess Diana, by Timarete, the first female artist upon record; a painting, by Apelles, of Alexander grasping a thunderbolt, purchased for 20 talents of gold. The shrine was adorned by Praxiteles and his son Cephisodorus; and the walls by Parrhasius and Apelles. The priests who served in the temple suffered emasculation, and the sacred virgins were devoted to inviolable chastity. They were eligible only from the higher classes of the citizens, and enjoyed a great revenue with numerous privileges, in addition to the presents received from the crowds of worshippers who flocked to the annual festivals. Their luxurious mode of living, and particularly the cost of their dyed vestments, are described by ancient writers in the most extravagant terms. The Asiarchs mentioned by Luke, (Acts xix. 31,) were the principal officers chosen by the community of the Asiatic cities, to preside over the games celebrated at Ephesus in honour of Diana, some of whom might also have been priests of the temple. Among other privileges, the sacred edifice afforded an asylum to those who sought its protection. The inviolable space at first extended one furlong, and was afterwards increased, first by Mithridates, next by Mark Antony, so as to include a part of the city; but, in consequence of the disorders which attended the exercise of such a privilege, it was entirely revoked by Tiberius, who declared, that even the altar itself should not protect a criminal from justice. This celebrated edifice, after suffering various partial demolitions, was finally burnt by the Goths in their third naval invasion, A.D. 260; and travellers are now left to conjecture even as to its site and its foundations; but the confused heaps of architectural fragments which still remain, sufficiently testify the ancient grandeur of Ephesus. A part of the aqueduct which conveyed water into the city from the spring of Halitza, still subsists; and the pillars which support the arches are of fine marble; but this structure is generally believed to have been raised by the Greek emperors, out of the ruins of Ephesus. A high wall, at the circular end of the stadium, is perfect, constructed of heavy rough stones; and the gate of the left wing, built of white marble, is nearly entire, but is also made up of fragments of former buildings, and must have owed its origin to a later age. Two vast gateways of a theatre or a Naumachia, and some walls of brick, faced with large marble slabs, supposed to have been either a part of the temple of Diana, or of the church of St John, form the other principal objects of any magnitude. At Aiasoluk or Ajasoluk, once the rival of the parent city, and the residence of the Saracens princes in the 14th century, is a large portal, formerly leading to the citadel, wholly built with Roman tiles, and faced with polished marble. Over the gateway, and above a very rich frieze, are three pieces of exquisitc sculpture, one of which, in alto relievo, represents the bringing of the body of Patroclus to Achilles. For some unknown reason, the Greeks call it the Gate of Persecution, and believe that it represents the martyrdom of Christians. Aiasoluk itself is a miserable village of mud cottages, and about a dozen small square buildings of brick, the ruins of oratories or baths, inhabited by 30 or 40 families of Turkish herdsmen. Its name is considered by some as a Turkish word, signifying the temple of the moon, in reference to the temple of Diana; but is supposed, by others, to be a corruption of Aiasoluk, the modern Greek of Αϊας Ὀλυμπίων, referring to the residence there of the evangelist John. Even the vale of Ephesus has undergone a total change; and the town could never be supposed, by an observer ignorant of its history, to have had a fine communication with the sea. The Cayster, formerly navigable, is now choked with sand, and flows through sedges, which render it almost invisible. Atalmenus Philadelphus, king of Pergamus, in order to improve the port, which was shallow and incommodious, was persuaded by an architect to construct an extensive mole; but, by the interruption thus given to the current, the earth brought down the river to the port, and even encroached some miles on the dominion of the sea.

When the city was taken by the Turks in 1300, "the desolation was so complete," says Rycart, "that the temple of Diana, and the church of Mary, will equally elude the search of the most industrious traveller." EPICURUS. A celebrated philosopher of ancient Greece, and the founder of that sect which flourished under his name, was born at Gargettus, a village of Attica, in the 100th Olympiad. He was the son of Nocles and Chares, of the illustrious family of the Philaides at Athens. At the age of eighteen, he commenced his philosophical studies in this central seat of learning; during the period when Xenocrates and Aristotle were engaged in exploring the most profound mysteries of science, and extending the circle of human knowledge.

Having acquired an high reputation for natural genius, extensive learning, and patient investigation, when about thirty years of age, he instituted, at Athens, a new philosophical school, and propounded to crowded audiences the peculiar tenets of a system of physical and moral science, which was different, in many essential points, from the doctrines that were taught by the most popular sages of those times. For the grand outlines of his theory of the universe, indeed, he was indebted to the previous labours of Leucippus and Democritus, the most ancient atomic philosophers; but from the sublime conceptions and plastic genius of Epicurus, these broken and discordant features first acquired such a rational form and consistency, as entitled them to the name of a system.

His theory of morals was as much opposed to the rigid maxims of the Stoics, as his life and conversation contrasted with the ascetic habits of the disciples of that celebrated school. In the unassuming walks of a delightful garden, Epicurus enjoyed the society of his friends, and delivered his instructions to his numerous pupils; whence the institution was denominated the School of the Garden, as that of Plato was called the Academy, that of Aristotle the Lyceum, that of Zeno the Porch, and that of Antisthenes the Cynosarges.
His manners were easy and affable; his life temperate and virtuous. Having devoted his days to the propagation of science, he died of an inflammation, occasioned by a stone in the bladder, after suffering the most excruciating pain with admirable composure and patience, in the 127th Olympiad, and the seventy-second year of his age.

It is unnecessary for us, in this place, to enter into any discussion respecting the physical principles inculcated by Epicurus, as we have already exhibited a view of his cosmological hypothesis in a former article: (See Atoms. 2.4 Philosophy.) But whatever objections the combined lights of reason and revelation may have afforded us against the principles of that system, it must still be acknowledged to have been the offspring of a bold, vigorous, and scientific mind; and it is, perhaps, the only rational profane theory, on the subject of cosmogony, which has had sufficient merit to attract respectable disciples in modern times.

The moral principles promulgated by Epicurus have afforded a theme of reprehension to the ascetic philosophers of all ages; and, by a singular misconception of the natural tendency of his opinion, the very name of that illustrious sage has been converted into an epithet expressive of every thing that is unprincipled, licentious, base, and grovelling, in human conduct and manners. Having assumed, as the basis of his ethical system, the principle, that pleasure is the chief good of man, it has been unwarrantably supposed, that his doctrines give countenance to habitual intemperance, and even recommend the unrestrained gratification of every illicit passion. Nothing, however, can be more unjust than such a representation of the moral theory of Epicurus. His system, indeed, as we have already observed, was directly opposite to that of the Stoical school. He rejected the absolute doctrine of fatality, which constituted the foundation of the philosophy of Zeno, and boldly contended for the free agency of man: a principle, without the admission of which it was vain to attempt to erect any rational system of morality. Disclaiming the external aid of gravity in speech, and of any singular austerity in dress and demeanour, and being himself naturally endowed with an affable and cheerful disposition, he deemed it not necessary for a wise man to be morose, but taught his disciples, on the contrary, to look for pleasure in the pursuit of wisdom, and to consider happiness as the concomitant of virtue. "Wisdom," says Epicurus himself, in his epistle to Menoeceus, "is the chief blessing of philosophy, since she gives birth to all other virtues, which unite in teaching us, that no man can live happily who does not live wisely, conscientiously, and justly; nor, on the other hand, can he live wisely, conscientiously, and justly, without living happily; for virtue is inseparable from a life of happiness, and a life of happiness is equally inseparable from virtue." Such principles, whether resulting from correct views of human nature or not, cannot surely be considered as holding out any encouragement to intemperate conduct, or indulgence in illicit pleasures. "Those," says one of his disciples, "whom we call lovers of pleasure, are real lovers of goodness and justice; they are men who practise and cultivate every virtue; for no true pleasure can exist without a good and virtuous life. When we assert, then, that pleasure is the chief good, the prime felicity of man, we do not mean the pleasures of the luxurious and the libidinous, the pleasures of the taste, the touch, or any of the grosser senses, as the ignorant, or those who wilfully mistake our opinions, maliciously assert; but what constitutes pleasure with us, is the possession of a body exempt from pain, and a mind devoid of perturbation," &c. The summum bonum of Epicurus, therefore, was nothing else than the mens sana in corpore sano of the Roman poet; he proposed to conduct mankind to happiness, not through the deceitful labyrinths of sensual gratification, but along the pleasant paths of knowledge and of virtue.

Among those, indeed, who controverted the doctrines of Epicurus, there were some who ventured to arraign his personal character, and who had recourse even to falsehood and forgery, in order to vilify and degrade him in the opinion of the people. These attempts, it must be confessed, however unjustifiable, have been too successful; as the vulgar prejudices of mankind, from the age of that philosopher down to the present times, sufficiently evince. But the malicious libels, which were industriously circulated, and too readily believed, against the moral character of Epicurus and his disciples, are abundantly refuted by the concurrent testimony of the most respectable authorities—of men who, although they might dissent from his principles, yet bore witness to the virtuousness of his life, and to the purity and excellence of his precepts.

In reality, both the Stoic and the Epicurean professed temperance and virtue, though from opposite principles. According to the former, virtue consisted in a total subjection of the passions, and in the constant and habitual practice of austerity and discipline. The Epicurean, on the other hand, assumed pleasure as the chief good, but, at the same time, sought this pleasure in a proper restraint of the desires and passions, and in the attainment of wisdom, and the exercise of virtue. Pain, according to the Stoic, ought to be considered as an object of indifference, beneath the regard of a wise man; with the Epicurean, on the contrary, it was a great evil, and to be avoided by all means. The theory of the latter sect preserved the influence of the social and moral affections entire; while that of the former evidently tended to produce ascetic apathy and indifference. We shall have no reason, therefore, to quarrel with the ethical system of Epicurus, if its principles be only understood in the same sense in which he seems to have elucidated them. To teach mankind the true road to happiness, has been the professed object of almost every theory of morals; and of all those means by which we can promote it, happiness it will be readily admitted, that there are none more efficacious than the cultivation of temperate and virtuous habits, and the exercise of our intellectual faculties, and benevolent affections.

The doctrines of Epicurus long continued to be favoured by the Romans; and his school was found to flourish under the emperors, after other institutions had begun to decay. The most celebrated adherents to this system were the elder Pliny, Celsus, Lucian, and Diogene Laertius. The Epicurean theory, however, was not encouraged at Alexandria, which, after the decline of Grecian learning, became the chief seat of literature and science; where the eclectics; who still continued to call themselves Platonists, superseded every other school. In the earlier ages of the Christian church, it fell into utter neglect and obscurity; but, during the 15th century, the doctrines of Epicurus again began to receive some encouragement; and they were subsequently revived in the 17th century, by the writings of Gassendi, Du Rondelle, and others. See Diogenes Laertius X. Gassendi and Rondellius, or Du Rondelle, de Vit. et Mor. Epicur. Des Courtils, Sur la Morale d'Epicure. Le Blane de Guilel. French Translation. of Lucretius, Paris, 1785, 2 vols. 8vo. Brucker, Cud- worth, Bayle, Mason Good's Lucretius.
EPICYCLOID, in Geometry, is the curve generated by any point in the plane of a moveable circle, which rolls either on the inside, or the outside of the circumference of a fixed circle. If the circles be both in the same plane, the curve generated will be the plane epicycloid.

If again the moveable and fixed circles be in different planes and the former be the base of a right cone, that rolls on the surface of another right cone, the base of which is the latter, so that the vertices of the cones are at the same point; then, in this case, the curve generated by any point on the plane of the moveable circle is called a spherical epicycloid; because the generating point being always at the same distance from the common vertex of the cones, the curve described by it will be on the surface of a sphere.

If a circle roll along a straight line, any point in the plane of the circle will generate a curve, which is called a cycloid. The three classes of curves evidently belong to the same family; for if we suppose the cones by which the spherical epicycloid is generated to change to cylinders, by their axes becoming infinitely long; then, the spherical will change to a plane epicycloid; and if again we suppose one of the cylinders to change to a plane, by the radius of its base becoming infinite, the epicycloid will be changed to a cycloid.

Galileo appears to have been the first that noticed particularly the cycloid about the year 1599. From the elegance of its form, he was led to regard it as a proper figure for the arches of a bridge; he endeavoured to find its area, but did not succeed, on account of the imperfect state of mathematical analysis at that time. It was he that gave the curve the name by which it is now commonly known.

Merriens, a learned Frenchman, also turned his attention to the cycloid, about the year 1615; but neither was he able to square it. Happening, however, in the year 1628 to become acquainted with Roberval, he proposed the problem of squaring the curve to him; but he also was unable to accomplish it. However, this circumstance led Roberval to study the works of the Greek mathematicians, particularly the writings of Archimedes, and about six years afterwards, when Mersennus again proposed the problem to him, he effected its solution. His success was communicated by Mersennus to Descartes, as a thing of importance, but he did not think there was much merit in the discovery. He was not made acquainted with the demonstration; but in his answer to Mersennus, he sent a sketch of one. Afterwards, when Roberval, mortified by the opinion of Descartes, retaliated by saying, that he had discovered his demonstration by his knowing beforehand what ought to be the result, the latter investigated the method of drawing tangents to the curve, and sent his solution to Mersennus, challenging Roberval, and also Fermat, with whom he then had a dispute, to resolve the same problem. Roberval made various vain attempts, and sent five or six different solutions; and it is even supposed that in the end he availed himself of the true solution of Fermat, which had come into the hands of his friend Mersennus, as Descartes called on him, but in vain, for a demonstration.

Galileo having been informed by Mersennus about the year 1639, that the question of the area of the cycloid was then greatly agitated among the French mathematicians, but, as it appears, without having been made acquainted with what had been found, he requested Cavalierius to attempt its solution. Cavalierius tried it, but did not succeed; however, after the death of Galileo, which happened in 1642, his disciples Torricelli and Viviani, were more successful; the former found the area, and the latter the method of drawing tangents to the curve. The claim of Torricelli to the honour of his discovery was contested by Roberval; but the charge of plagiarism, which he brought against the Italian mathematician, has not been believed by his countryman Montucla, who has discussed the controversy in the second volume of his History of Mathematics, second edition.

The cycloid, the source of so much contention, and on that account compared to the golden apple thrown by Discord among the gods, was again brought into notice by Pascal. This philosopher, not less celebrated for his piety and zeal in defence of the Christian religion, than his mathematical invention, took the cycloid as the subject of his meditation in those sleepless nights which he passed, in consequence of bad health; and he soon extended his discoveries beyond what was then known. He was not of a disposition to boast of his discoveries in geometry; but some of his pious friends supposed that it would be useful to have it known, that the man who had defended religion and Christianity against infidelity, was perhaps the most profound thinker, and the greatest geometer in Europe. They therefore requested that he would try the skill of the mathematicians his cotemporaries, by proposing publicly his problems on the cycloid. He took their advice; and, under the assumed name of A. Detonville, he addressed a circular letter to the geometers, in 1658, inviting them to resolve his problems, and promising forty pistoles to the author of the first solution, and twenty to that of the next, requiring them also to be sent to Paris by an assigned time. Only two contended for the prize; Lalonde, a French mathematician, and our countryman Dr Wallis. As the former had merely made a partial attempt to resolve the problems, and had failed, his claims were immediately set aside. Dr Wallis, however, had been more successful, yet he had committed some mistakes, and, on this account, the prize was not awarded to him. There were others, who, without aspiring to the prize, sent solutions of one or other of the problems to Pascal. Of this number were, Slussius; the prelate Richi; the celebrated Huygens; and Sir Christopher Wren, who discovered the rectification of the curve. Pascal published his own solutions in the beginning of the year 1659, in a work entitled Letters from A. Detonville to M. de Caracci. In the same year, Dr Wallis published a work on the cycloid, and other curves, in which he resolved some of Pascal's problems by his Arithmetica of Infinites; and, in the year following, Lalonde also published a treatise on the cycloid; and another work appeared about the same time from the pen of P. Fabri, the Jesuit.

The cycloid is remarkable, as well on account of its mechanical as of its geometrical properties; and Mr Huygens discovered some of the most interesting of both kinds. To the latter class belongs the property, which we shall demonstrate in this article, by which he shewed how a pendulum may be made to vibrate in an arc of a cycloid; and to the former, the very beautiful property, that all vibrations of a pendulum in arcs of a cycloid, are performed in equal times. See Mechanics.

The very curious problem proposed by John Bernoulli, viz. "to find the path along which a body may roll from one given point to another, in the shortest time possible, the points being supposed neither in the
180  

EPICYCLOID.

1. **Of the Cycloid.**

**Definitions.**

1. If a circle, EPF, roll along a straight line AB, (Plate CCLIII. Fig. 1.), so that every point of the circumference may touch the line in succession; and if P be that point of the circumference which was in contact with the straight line at the beginning of the motion, when the circle has made a complete revolution, the point P will have described a curve line APDB, which is called a **cycloid**, also sometimes simply a **cycloid**.

2. As before, a circle roll along a straight line a b, (Fig. 2. and 3.), and Q be that point of its circumference which was in contact with the straight line at the beginning of the motion; and P be a given point in OQ, the radius of the circle, (Fig. 2.), or in the radius produced (Fig. 3.), when the circle has completed a revolution, the point P will have described a curve line APDB, which is called a **prolate or infected cycloid**, if the point P be within the circle (Fig. 2.); and it is called a **curtate cycloid**, if the point is without the circle.

3. In each of the three cycloids, the circle EF is called the **generating circle**.

4. The straight line AB, which joins the points in each cycloid, where the motion of the point that describes the curve begins and ends, is called the **base** of the cycloid.

5. A straight line CD which bisects the base at right angles, and terminates in the curve, is called the **axis**; and the point D, in which it meets the curve, is called the **vertex** of each kind of cycloid.

6. A straight line drawn from any point in the curve, perpendicular to the axis, is called an **ordinate** to the axis; and the segment of the axis between the vertex and an ordinate, is called an **abscissa**.

**Corollary to Def. 1. and 2.** If the generating circle be supposed to continue to roll along the base produced, in each case the generating point will describe other cycloids, exactly like the first. In fact, they may be considered as forming with it a continuous curve, which never returns into itself, but goes on indefinitely.

**Proposition I.**

In any cycloid, the base is equal to the circumference of the generating circle.

In the **common cycloid** APB, (Fig. 1.) every point in plane the circumference of the generating circle will manifestly touch the base, without sliding along it, while the Fig. 1 circle makes a complete revolution; therefore, the base of the cycloid is equal to the circumference of the circle.

In the **prolate and curtate cycloids**, (Figs. 2. and 3.) Figs. 2, 3. Q being the point of the circumference of the generating circle, which touches the line a b at the beginning and end of the motion; and P being the point in the revolving radius OQ, which generates the cycloid APDB, it is manifest that at the beginning of the motion, the line QP will have the position a A, a perpendicular to a b; and at the end, it will have the position b B, another perpendicular to a b; therefore a A, b B are equal and parallel, and consequently AB is equal to a b, which again is manifestly equal to the circumference of the generating circle (Def. 2.).

**Prop. II.**

In the three kinds of cycloids, the axis is equal to twice the straight line drawn from the point that generates the curve to the centre of the generating circle.

It is evident from the generation of the curves, that as the circle rolls along the base AB of the common cycloid (Fig. 1.) or along the line a b of the curtate and prolate cycloids, (Figs. 2. and 3.) which is parallel and equal to the base AB, the centre advances in a straight line parallel to AB; and that the part of the line described by the centre from the beginning of the motion is equal to the arc of the circle that has been applied to AB (Fig. 1.), or to a b (Fig. 2. 3.). Therefore, when the circle has completed half a revolution, its centre O will be in CD, the axis, and the point P that generates the curve, will be at D, the vertex; so that the distance between the centre and the vertex is equal to the line OP: but the height of the centre of the circle above the base is the same as it was at the beginning and end of the motion, that is, it is equal to the same line OP; therefore the distance of the vertex from the base is equal to twice OP, that is, to twice the distance between O, the centre of the circle, and the point P that describes the curve.
Con. A circle described on the axis of the common cycloid, as a diameter, is equal to the generating circle.

**Prop. III.**

If a circle be described on the axis of a common cycloid as a diameter, and an ordinate be drawn to the axis; the segment of the ordinate between the circle and the cycloid is equal to the arc of the circle between the ordinate and the vertex.

Let $DHC$ (Fig. 4.) be the circle described on the axis $DC$ as a diameter, and $PHG$ the ordinate; the straight line $PH$ is equal to the circular arc $HD$.

Let $FPE$ be the position of the generating circle when the point in the circumference that describes the cycloid is at $P$. The circles $CHD$, $EPF$ are equal, and the lines $HG$, $PI$ are manifestly the half-side of chords equally distant from the centre; therefore $PI$, $HG$ are equal, (See Geometry.) and $PH = IG = EC$. Now the semicircumference $CHD$, $EPF$, is equal to the straight line $CA$ (Prop. 1.), and the arc $CH$ or $EP$ is equal to $AE$, part of that line to which it has been applied by the revolution of the circle; therefore the remaining arc $HD$ is equal to $EC$, that is to $PH$.

Con. Let the abscissa $DG$ be denoted by the letter $x$, and the ordinate $PG$ by $y$; then, if the radius of the generating circle be expressed by $a$, and the arc $DH$ by $z$; the nature of the common cycloid will evidently be expressed by the equations

$$\begin{align*}
x &= a - \cos z, \\ y &= a + \sin z.
\end{align*}$$

By exterminating $z$, and its functions $\cos z$ and $\sin z$, the relation of $x$ to $y$ will be found, which, however, cannot be expressed in finite terms; therefore the curve is transcendental. The relation of the abscissa and ordinate may, however, be expressed in infinite terms, by a fluxional equation. See Fluxions.

**Prop. IV.**

If a circle be described on the axis of a prolate or curtate cycloid as a diameter, and any ordinate be drawn to the axis, the arc of the circle between the vertex and the ordinate will be to the segment of the ordinate between the cycloid and circle, as the axis to the diameter of the generating circle.

Let $DHC$ be a circle described on the axis $DC$ as a diameter, and $PG$ an ordinate meeting the circle in $H$; and let $DE$ be the diameter of the generating circle; the arc $DH$ is to the straight line $PH$, as $DC$ to $DE$.

Let $EQF$ be the position of the generating circle when the point that describes the curve is at $P$; and let $FE$, its diameter, which is perpendicular to $a$, meet the ordinate in $I$; draw $IO$ to the centre, and on $O$, with $PO$ as a radius, describe a semicircle $MPN$. The semicircles $MPN$, $DHC$, being equal (Prop. 2.), and their centres at the same distance from $a$, and consequently from $AB$ and $PG$; the lines $PI$, $HG$, which are the halves of chords at equal distances from the centres of equal circles, are equal; also, the arc $PN$ is equal to the arc $HC$; and the arc $PM$ to the arc $HD$. Now, the semicircumference $EQF$ of the generating circle being equal to $AC$, half the base; and the arc $EQ$ equal to the straight line $a$, along which it has rolled; that is to $AN$, a part of the base, the remaining arc $QF$ is equal to $NC$, the remainder of the base; but because $PI = HG$, therefore $PH = IG = NC$; therefore the arc $QF$ is equal to the straight line $PH$. Now, from similar figures, $OP$: $OQ = arc PM = arc DH$; $arc QF = straight line PH$; therefore $CD: CD = arc DH: PH$.

**Con. I.** The arc $DH$ is to the straight line $PH$ as the circumference of the circle $DHC$ to the base $AB$. For the base is equal to the circumference of the circle $FQE$.

**Con. 2.** Let $DG = x$, $PG = y$, arc $DH = z$; and let $a$ be the radius of the circle described on the axis, and $b$ the radius of the generating circle; then because by the theorem $HI = \frac{a}{z}$, the nature of the prolate and curtate cycloids will be expressed by the two equations

$$\begin{align*}
x &= a - \cos z, \\ y &= b \frac{a}{z} + \sin z.
\end{align*}$$

**Prop. V.**

In the common cycloid, if a circle be described on $DC$, the axis, as a diameter; and from any point $P$ in the curve, an ordinate $PG$ be drawn to the axis, meeting the circle in $H$; a tangent $PV$ to the cycloid shall be parallel to $HD$, the chord of the arc between the vertex and the ordinate.

At the points $H$, $D$ draw the tangents $HR$, $DR$, the latter of which will be parallel to the ordinate $PG$: draw also another ordinate $PH$ indefinitely near to the former, so that the indefinitely small arcs $PP$, $HH$ may be considered as coinciding with the tangents $VP$, $RH$; lastly, draw $PQ$ parallel to $HH$, and join $D$ and $H$ meeting $PG$ in $m$.

Because $PH = arc DH$, and $PH = arc DH$; therefore $PH = PH = arc DH$, that is, $PQ = HH$; but the triangles $HLM$, $HDD$ being similar, and $DH = DD$, therefore $HLM = HDM$; hence $PQ =🀛M$, and $PQ = PH$; the figure $PQPH$ is thereon a parallelogram, and consequently $PV$ is parallel to $HD$, or to $HD$.

**Prop. VI.**

The arc $DP$ of the common cycloid is double the chord $DH$ of the corresponding arc of the generating circle.

Let the ordinate $PH$ be indefinitely near to $PHG$; join $DH$, meeting $PG$ in $m$, and draw $Hn$ perpendicular to $HP$. Because the arcs $PP$, $HH$ are indefinitely small, as in last proposition, they may be considered as coinciding with tangents to the curves. And because $PP$ is parallel to $DD$, or $DD$ (Prop. 5.) the figure $PQPH$ is a parallelogram; hence $PH = PH$; but $Hn = HH$, as was shown in Prop. 5; and therefore $PH = PH = n$, and $Hn = Hn$. Therefore $PP = Hn$. Now $PP$ and $n$ are evidently the increments which the cycloidal arc $DP$ and the chord $DH$ receive by the ordinate changing its position from $PG$ to $PP$; therefore the increment of the arc is always double the increment of the corresponding chord.

Suppose now the arc and chord to be generated by the ordinate moving parallel to itself from the vertex along the axis, then because the arc and chord begin together, and the increment of one is double that of the other, the arc will always be double the corresponding chord.

Con. The whole cycloid $ADB$ is four times the diameter of the generating circle, or four times the axis.

**Prop. VII.**

If $DM$ be drawn from the vertex of the cycloid parallel to the base, and from any point $P$ in the curve an ordinate $PHG$ be drawn to the axis, meeting the generating circle in $H$; and $PL$ be drawn perpendicular to $DM$; the external cycloidal area $DLP$ is equal to...
the area contained by the circular arc $DH$, and the straight lines $DG$, $GH$.

Take a point $p$ in the curve, indefinitely near to $P$; and draw the co-ordinates $phg$ and $pl$; join $DH$, and complete the indefinitely narrow parallelograms $Gv$, $lr$. Because the indefinitely little arc $lp$ may be considered as a straight line, which is parallel to $DH$, (Prop. V.), the triangles $Ppr$, $HGd$ are similar; hence $pr:pr$, $GD:HG$; that is, $Gr:pl$, $PL:GH$; since then the rectangles $Gr$, $lr$ have their sides reciprocally proportional, they are equal. (See Geometry.)

Now the rectangle $Gr$ may be considered as the increment of the circular space $DhG$; and the rectangle $lr$ as the increment of the cycloidal space $DlP$, corresponding to a change in the position of the ordinates from $PhG$ to $phg$; for as to the triangles $hHv$, $PPr$, they vanish in respect of these rectangles: therefore the increments of the spaces $DhG$, $DlP$, are equal, and consequently the spaces themselves are equal.

Con. If AM be perpendicular to $DM$, the whole cycloidal space $(ADM)$ is equal to the semicircle $DHC$.

**Plate CCLIII.**

**Fig. 8.**

If $PHG$, an ordinate to the axis, meet the generating circle in $H$, and the chord $HC$ be drawn to the middle of the base, and $PK$ parallel to $HC$, meeting the base in $K$; the space bounded by the cycloidal arc $DP$, and the straight lines $PK$, $KC$, $CD$, shall be triple the corresponding space bounded by the circular arc $DH$, and the straight lines $HC$, $CD$.

Draw $HN$, a tangent to the circle, meeting the base in $N$; also draw the ordinate $phg$ indefinitely near to $PHG$, meeting $HC$ in $m$; join $hc$, draw $pk$ parallel to $hc$, and $ks$ parallel to $CH$ or $KP$. Because the triangles $CNh$, $mhH$, are similar, and $NC=NH$; therefore $hm=khH$; and because $p+khH=arcHD=kh\parallel pmh\parallel phm$, that is, because $p+khH=hm+kh$; therefore $p=phm$. And because $ks$ is parallel to $cm$, and $kp$ to $ch$, therefore $ps=phm$, and $p=2ps$; hence the parallelogram $sk$ is double the triangle $pkS$; and the quadrilateral $pks$ is triple the triangle $pkS$, that is $hcm$. Now the former of these is manifestly the increment of the space $PKCD$ corresponding to a change in position of the chord from $CH$ to $Ck$, and the latter is the increment of the space $HCD$; therefore the space $PKCD$ is triple the space $HCD$.

Con. 1. The cycloidal area $DAC$ is triple the semicircle $DHC$.

Con. 2. The interior cycloidal space $PDC$, is the excess of three times the space contained by the arc $HD$, and the lines $HC$, $CD$ above the trapezoid $PGCK$.

**Prop. IX.**

Let $AB$ be the base of a cycloid, $ADB$ and $CD$ its axis: In $DC$ produced, take $CV=CD$; and let a semicycloidal, the same as $DB$, be put in the position $AV$; and another semicycloidal, the same as $DA$, in the position $BV$: Suppose now that a thread is fastened at $V$, and applied along the curve, so as to terminate at $A$; then, if it be unfolded, beginning at the point $A$, its extremity $P$ will describe the cycloid $ABD$.

Draw $AR$ perpendicular to $AB$, and equal to $CD$; and describe the semicircle $AYR$. Let $PX$, the part of the thread which has been unwrapped from $AX$, meet $AC$ in $T$; draw $NX$ perpendicular to $AR$, meeting the circle in $Y$; and $PG$ perpendicular to $DC$, meeting the circle in $H$; and join $AY$, $CH$.

Because $XTP$, the part of the thread unfolded, is a tangent to the curve, it is parallel to $AY$ (Prop. 5); and because it is equal to the arc $XA$, it is double $AY$ (Prop. 6), that is double $TX$; therefore $TX=TP$; and as, on this account, perpendiculars from $X$ and $P$ on $AC$ will be equal; $AZ$ is equal to $CG$: Now, the circles $AYR$, $CHD$ are equal, therefore the arcs $AY$, $CH$ will be equal, and the chords $AY$, $CH$ equal and parallel; hence $PT$ is equal and parallel to $HC$, and $PH$ is equal to $CT$; But $AC$ being equal to half the circumference $CHD$, and $AT$ or $XY$ equal to the arc $AY$ (Prop. 3), that is, to the arc $CH$; therefore $TC$, or $PH$, is equal to the arc $DH$: Hence the point $P$ is in a cycloid, of which $CHD$ is the generating circle (Prop. 3), and therefore it is in the cycloid $ADB$.

**Note.** The property of the cycloid described in this proposition was discovered by Huygens, and applied to the motion of a pendulum. Suppose the line $VD$ to be perpendicular to the horizon, and two thin plates of metal to be bent into the form of semicycloids, and fixed in the positions $VA$, $VB$; then, if a pendulum were formed by fixing a weight to the end of a thread $PVX$, and made to vibrate between the plates, the weight $P$ will, by its motion, describe the cycloid $ADB$.

This manner of describing a curve by the extremity of a thread which is unfolded from another curve, has given rise to the theory of involutes and evolutes, one of the most elegant speculations of modern geometry. See *Fluxions*.

For the application of the properties of the cycloid to mechanics, see *Mechanics*.

## II. Of Epicycloids.

**Definitions.**

1. Let $AEB$ be a given fixed circle, and $EPF$ an Epicycloidal circle, which rolls either on the outside of the former (as in Fig. 10.), or on the inside (as in Fig. 11.), and in the same plane; also, let $p$ be a given point in a line drawn from $O$, the center of the moveable circle, through $P$, a given point in its circumference; and at the beginning of the motion, let $P$ be at $A$, the point of contact of the two circles, and the point $p$ at $a$; then, while the circle makes one complete revolution, by rolling along the arc $AB$, the line $OP$ will revolve about $O$ as a centre, and the point $p$ will describe a line $apdb$, which is called an epicycloid.

2. When the generating circle revolves on the outside of the circumference of the fixed circle, the line described is the *exterior* epicycloid; and when the generating circle rolls on the inside of the circumference, the line described is the *interior* epicycloid.

3. The circle $EPF$ is called the generating circle, and the point $p$ the generating point.

4. A straight line drawn through the centre of the fixed circle, and $H$, the middle of the base, is called the axis; and the point $d$ in which the axis meets the curve, is called the vertex.

**Corollaries to the Definitions.**

Cor. 1. The points $a$ and $b$, the extremities of the epicycloid, are in $CA$, $CB$, the radii of the circles drawn, to the extremities of the base.

2. The base of the epicycloid is equal to the circumference of the generating circle.

**Scholium.** It is evident from the manner of describing the epicycloid, that after the generating circle has made a complete revolution, if it be supposed to continue its motion, a series of epicycloids will be described.
Prop. I. Problem.

To find the equations which express the nature of any epicycloid described on a plane.

Let HEX be the fixed circle, and C its centre; also let F'H be the generating circle when it has made exactly half a revolution. Then its centre O' will be in the axis CH; and the generating point will be at D, the vertex of the curve.

Suppose now that the generating circle has rolled along the arc HE, so that its centre has advanced from O' to O, and the revolving radius from the position O'D to the position OP', while the generating point P has described, by its motion, the epicycloidal arc DP. Draw PK and OG perpendicular to CD, and OM perpendicular to PK, and produce PO to meet the generating circle in L, then L will be the point of the generating circle that was in contact with H, and therefore the arcs LE, HE are equal.

Taking the centre of the fixed circle as the origin of the co-ordinates,

Put CK, the abscissa, $= z$,
KP, the ordinate, $= y$,
Arc HE = arc LE, $= a$,
CE, the rad. of fixed circle, $= c$,
OE, the rad. of gen. circle, $= z$,
OP, the dist. of gen. point from the centre, $= b$.

Then $\frac{z}{c}$ is the arc of a circle, whose radius is unity, which measures the angle $\angle CHF$; and, in like manner, $\frac{z}{a}$ is the measure of the angle $\angle LOE$, or $\angle POF$;

hence $\frac{z}{c} + \frac{z}{a} = \frac{1}{c} + \frac{1}{a}$ is the measure of the angle $\angle POM$:

Hence

$CG = CO \times \cos \angle CHF = (c+a) \cos \frac{z}{c}$,
$OG = CO \times \sin \angle CHF = (c+a) \sin \frac{z}{c}$,
$OM = PO \times \cos \angle POM = b \sin \frac{1}{c} + \frac{1}{a} z$,
$PM = PO \times \sin \angle POM = b \cos \frac{1}{c} + \frac{1}{a} z$.

Now $\frac{z}{c} = CG + OM$, and $\frac{y}{c} = OG + PM$; therefore

(A)

$x = (c+a) \cos \frac{z}{c} + b \cos \left(\frac{1}{c} + \frac{1}{a}\right) z$,
$y = (c+a) \sin \frac{z}{c} + b \sin \left(\frac{1}{c} + \frac{1}{a}\right) z$.

These two equations express generally the nature of all epicycloids, whether exterior or interior; because, although in investigating them, we have supposed the generating circle to be without the fixed circle. By a well known principle in mathematical analysis, we have only to change the sign of $a$ and $b$ from + to −, thereby indicating, that the lines which these letters represent, are to be considered as having a contrary direction to that which they had in the former case, and the equations will be adapted to the case of interior epicycloids.

In the preceding equations, the co-ordinates are expressed in terms of the arc, which the generating circle has rolled over, reckoned from H, the middle of the base, (Fig. 12.) but it will be convenient to have them also expressed by the arc described from the beginning of the motion. Draw a straight line from C through A, (Fig. 13.) the first point of contact of the two circles, and let us suppose, that the generating circle has CCLIII. rolled along the arc AE, while the generating point, which was at first at A', has described the epicycloidal arc A'P. Let P meet the circle in N, then the arcs EN, EA are equal. Produce PO, CO to L and F; draw PQ, O'T perpendicular to CA; and OT perpendicular to QF. Put the abscissa $CQ = x'$, the ordinate $OP = y'$, the arc $AE = x'$; and, as before, put $CE = c$, $OE = a$, $PO = b$. Then the angle OCR, or O'T, is $\frac{x'}{c}$, radius being unity, and the angle NOE, or FOL = $\frac{x'}{a}$, therefore $TOL = \frac{x'}{c} + \frac{x'}{a} = \left(\frac{1}{c} + \frac{1}{a}\right) x'$.

Hence $CR = (c+a) \cos \frac{x'}{c}$,
$OR = (c+a) \sin \frac{x'}{c}$,
$PT = b \cos \frac{1}{c} + \frac{1}{a} x'$;

and since $x' = CR + TO$, and $y' = OR - PT$, we have

(B)

$x' = (c+a) \cos \frac{x'}{c} - b \cos \left(\frac{1}{c} + \frac{1}{a}\right) z$,
$y' = (c+a) \sin \frac{x'}{c} - b \sin \left(\frac{1}{c} + \frac{1}{a}\right) z$.

From this solution we may deduce the following consequences:

1. These two sets of formulae (A) and (B), enable us to find as many points in any epicycloid as we please, by the help of the trigonometrical tables. To do this, we must give particular values to the angle $\frac{z}{c}$, and $\frac{y}{c}$, we must find from the tables the values of the sines and cosines of $\frac{z}{c}$, and of $\left(\frac{1}{c} + \frac{1}{a}\right)$, and from these, the values of $x$ and $y$, the co-ordinates of points in the curve may be found; and, in these calculations, regard must be had to the signs of the sines and cosines, as is explained in our article Arithmetic of Sines.

2. If $c$ and $a$ be commensurable, the indeterminate arc $z$ may be eliminated from either of the formula (A), (B), and hence an equation may be found, which shall express the relation of $x$ to $y$ in finite terms. For example, if $c : a = 3 : 2$, so that $\frac{1}{c} + \frac{1}{a} = \frac{5}{2}$, then, from formula (A),
by these equations, and the equation \( p^{3} + q^{3} = 1 \), \( p \) and \( q \) may be eliminated; and the result will be an algebraic equation, involving \( x \) and \( y \) only, which will be the equation of the curve.

Hence it appears, that if the ratio of \( a \) to \( c \) can be expressed exactly by numbers, the epicycloid, which is an algebraic curve, which returns into itself; (Scholium to Def.) If, however, \( a \) and \( c \) be incommensurables, the elimination of \( z \) produces an equation of an infinite number of terms, and therefore in this case the curve is transcendental; and in this case it also never returns into itself.

3. As the order of the curve depends upon the ratio of the radii of the fixed and generating circles, it may be worth while to examine some of the more simple cases.

First let us take the case of a circle \( EPC \), (Fig. 14) which rolls on the inside of another \( AEH \), so as always to pass through its centre \( C \). In this case, \( b = a = \frac{1}{2} c \), because \( a \) lies now in a contrary direction; therefore, referring the co-ordinates to the line \( CA \), drawn through \( A \), the first point of contact of the two circles, we have by the formula (B),

\[
x = \frac{c}{2} \cos \frac{z}{c} + \frac{c}{2} \cos \left( -\frac{z}{c} \right).
\]

\[
y = \frac{c}{2} \sin \frac{z}{c} + \frac{c}{2} \sin \left( \frac{z}{c} \right);
\]

Now, if in the formula for the cosine and sine of \( a - b \), \( a \) and \( b \) being any arcs, \( \text{Arithmetic of Sines, Art. 10.} \) we suppose \( a = 0 \), and observe that then \( \cos a = 1 \), \( \sin a = 0 \), we shall have \( \cos (b - a) = \cos b \),

\[
\sin (b - a) = -\sin b,
\]

and therefore \( \cos \left( -\frac{z}{c} \right) = \cos \frac{z}{c} \sin \left( \frac{z}{c} \right) = -\sin \frac{z}{c} \); therefore

\[
x = c \cos \frac{z}{c}, \quad y = 0.
\]

This value of \( y \) shows, that the generating point is always in the axis \( CA \), and since the value of \( z \) is evidently the cosine of the arc \( z \), or \( AE \), the distance of the generating point from the centre at any time, is the cosine of the arc that has then been gone over.

The epicycloid in this case is therefore \( AB \), that diameter of the fixed circle which passes through the point \( A \) where the motion begins.

This conclusion is easily proved synthetically. For if upon \( O \), the middle of any radius of the fixed circle, a circle be described to pass through the centre, and meet a diameter in \( P \), and \( OP \) be joined, the angle

\[
POE \text{is manifestly double the angle } ACE; \text{ but } POE = \frac{1}{2} \text{ and } 2 \text{ arc } AE = \frac{AC}{PO} \text{; therefore arc } PE = \text{ arc } AE, \text{ and so } P \text{ is a point in the line, that would be described by the circle } EPC \text{ rolling on the inside of the circle } AEH.
\]

4. Next, let us suppose that the circle \( EP \) rolls on the outside of another \( AEH \), of the same magnitude, (Fig. 15,) and that the generating point departs from the first point of contact of the two circumferences.

In this case, \( b = a = c \), and we have by formula (B),

\[
CR = x = 2c \cos \frac{z}{c} - c \cos \frac{z}{c} \]

\[
PR = y = 2c \sin \frac{z}{c} - c \sin \frac{z}{c}.
\]

Let \( v = \frac{z}{c} \), then observing that \( \cos 2v = 2 \cos^{2} v - 1 \), and \( \sin 2v = 2 \sin v \cos v \), \( \text{Arithmetic of Sines, Art. 14.} \) we have, after substitution, \&c.

\[
x = c \cos v (1 - \cos v) \]

\[
y = 2c \sin v (1 - \cos v).
\]

Hence \( \frac{y^{2}}{v^{2}} = \frac{\sin^{2} v}{1 - \cos^{2} v} = \frac{1}{\cos^{2} v} \).

Let us put \( z = \pi x' \), so that instead of making \( C \) the beginning of the abscissae, we are now to reckon them from \( A \); and let \( v = v = p \), and we have from equations (1) and (2),

\[
x' = 2cp - c^{2} p^{3}.
\]

From these two equations, let \( p \) be eliminated by the usual method, \( \text{Algebra, Sect. 15.} \) and the result will be

\[
4c^{4} (x'^{2} + y^{2}) = (x'^{2} + 2x' + y^{2})^{3},
\]

the equation of the curve, which shews it to be a line of the fourth order.

This curve has been called the 'cardioid.' It has several remarkable properties: For example, if any straight line be drawn through \( A \), to meet the fixed circle again in \( V \), and terminate in the curve at \( P \) and \( P' \), then \( VP \) and \( VP' \) are each equal to \( AH \); and, consequently, all lines drawn through the given point \( A \), and terminating in the curve, are equal. By this property, any number of points in the curve may readily be found. Again, if tangents be drawn to the curve at the points \( P \), \( P' \), they will form a right angle at \( X \), their intersection.

5. As a third particular case, let us suppose the generating point to be in the circumference of the generating circle, and its radius indefinitely great. In this case (Fig. 16,) \( PE \), the part of the circumference of the generating circle between \( P \), the generating point, and \( E \), the point of contact, is to be reckoned a straight line, which being equal in length to the arc \( AE \), the epicycloid is the same curve as would be described by \( P \), the end of a thread \( PEH \), while it was unwrapped from a cylinder or circle \( AEH \), round which it was wound.

In this case, we have \( b = a = \infty \) an infinitely great quantity; and because, in general, \( \cos \left( \frac{z}{c} + \frac{z}{a} \right) = \cos \frac{z}{c} \cos \frac{z}{a} - \sin \frac{z}{c} \sin \frac{z}{a} \) and \( \sin \left( \frac{z}{c} + \frac{z}{a} \right) = \sin \frac{z}{c} \cos \frac{z}{a} + \cos \frac{z}{c} \sin \frac{z}{a} \) \( \text{Arithmetic of Sines; when } a \text{ is infinitely great, then } \cos \left( \frac{z}{c} + \frac{z}{a} \right) \)
If to the $P$, also to the $z$, let circle and pose $c$ $P$, $giJes$ (Fig. 17), and $\tan$ perpendicular at the $E$, property moreover, If $c \parallel EF$, $c$, $z$, an equation expressing a property of the curve, which is indeed sufficiently obvious; but the relation of $x$ to $y$ cannot be expressed by an algebraic equation, and therefore the curve is transcendental. This curve is called the involute of a circle.

**PROP. II.**

A tangent to an epicycloid at any point is perpendicular to a straight line drawn from it; to the point of contact of the generating and fixed circles.

Suppose two polygons $A$, $B$, $C$, $D$, $E$, &c. $N$, $2$, $3$, $4$, $E$, &c. of a great number of sides to be described about the fixed and generating circles (Fig. 17), and that the sides of the one are equal to those of the other. Suppose now the one polygon to roll on the outside of the other; then it is evident that the generating point $P$ will describe a series of arcs of circles, whose centres are the points $1$, $2$, $3$, $4$, $E$, &c. If now $PX$ be a tangent to a curve that touches all these arcs, at any point of contact $P$ it will be perpendicular to $PE$, the radius of the arc that is in contact with the curve at $P$. Imagine now the number of sides of the polygons to be infinite, then the epicycloid may be regarded as the curve that touches all the circular arcs, and $E$, a point where the polygons touch each other, will be the point of contact of the generating and fixed circles. So that the truth of the proposition is manifest.

**Con. 1.** Let $O$ be the point in which the centre of the generating circle crosses the axis (Fig. 18), and $DVI$ a circle described on $O$, with a radius equal to $OP$, (the distance of the generating point from the centre of the generating circle), and $H$ the point in which the generating circle touches the fixed circle, when its centre is at $O$. Then, if a circle be described on $C$ as a centre to meet the epicycloid in any point $P$, and the circle $DVI$ in $V$; and $PE$ be drawn perpendicular to the tangent $PX$, to meet the fixed circle in $E$; the normal $PE$ shall be equal to a straight line drawn from $V$ to $H$. Let $O$ be the centre of the generating circle when the generating point is at $P$; draw $OC$ to the centre, which will pass through $E$ (by the Prop.) and join $OP$, $OV$; and because $CO=CO$, $OV=OP$, and $CV=CP$, the triangles $COV$, $COP$ are equal; therefore the angles $HOV$, $EOP$ are equal; now $HO=EO$, and $OV=OP$; therefore the triangles $HOV$, $EOP$ are equal, and $HV=EP$.

**Con. 2.** If the generating point be in the circumference of the generating circle, a tangent to the curve at any point $P$ (Fig. 21) will pass through $F$, the extremity of the diameter of the generating circle which passes through $E$, the point of contact of the two circles

**Scholium.** From this proposition it appears, that if parallel rays of light fall on the concave circumference of a circle $Dd$ (Fig. 19.), they will, after reflection, be tangents to an epicycloid $DFA$, generated by a circle $FPE$, which rolls upon a circle $AEH$, having the same centre as the circle $DRd$, and its radius half the radius of that circle, and double the radius of the revolving circle; also the generating point being supposed to set out from $A$, the middle of the perpendicular radius $CR$. For let the generating circle be in any position $EPF$, $P$ being the generating point, and $CEF$ that radius of the circle $DFR$, which passes through the points of contact of the circles; draw $FG$ perpendicular to the diameter $Dd$, and join $FP$, which will touch the epicycloid in $P$, (Cor. 2.) The angle $EPF$ at the circumference is half an angle at the centre, on the same arc, and therefore is measured by $\frac{1}{2} \text{arc PE} - \frac{1}{2} \text{arc PE}$, that is by $\frac{\text{arc EA}}{\text{EC}}$; but this last arc is also the measure of the angle $ECA$, or $CFG$; therefore the angles $PFC$, $CFG$ are equal; and hence, if $GF$ be the incident ray, $FP$ is the reflected ray. See **Optics**.

Hence it appears, that in this case the epicycloid is the catacaustic curve, or the curve which passes through the intersection of any two parallel and contiguous rays, after they have reflected from the concave surface. This curve is beautifully shewn on milk in a bowl, by the reflection of the sun’s rays from the polished concave surface which rises above the surface of the milk.

When rays diverge from one end of the diameter of Fig. 23. a circle, and are reflected from the inside of the circumference, in this case also the catacaustic curve is an epicycloid, viz. the *cardioid:* (See Prop. 1) For let the circle $EPF$ roll on the outside of the equal circle $AED$, the point $P$ departing from $A$, and generating the epicycloid $APH$, through $E$, the point of contact of the circles, draw $CEF$, to meet the generating circle again in $F$; on $C$ as a centre, with $CF$ as a radius, describe a circle $HFD$; draw $FP$ to the generating point, and $FH$ to the end of the diameter of the circle $HFD$, which meets the epicycloid. Because $AE$ and $EP$ are equal arcs of equal circles, the angle $ACE$ at the centre is double the angle $EPF$ at the circumference. But because $CF=CH$, and consequently the angle $CHF=CFH$, the angle $ACE$ is double the angle $CFH$; therefore the angle $CFH$ is equal to the angle $CFP$; and consequently $HF$ being any incident ray, $FP$ is the reflected ray; moreover, $FP$ is a tangent to the epicycloid. (Cor. 2).

**Note.** In the remaining propositions, we shall always suppose the generating point to be in the circumference of the generating circle.

**PROP. III.**

Let $H$ be the middle of $HPA$, an exterior epicycle, $C$ the centre of the fixed circle, and $HVD$ the generating circle when its centre is in the axis $CH$. On $C$ describe an arc of a circle to pass through $P$ any point in the epicycloid, and meet the generating circle in $V$, and join $HV$. The chord $HV$ is to the epicycloidal arc $HP$, as the radius of the immovable circle to the sum of the diameters of the immovable and generating circles.

Take $p$, a point in the epicycloid, indefinitely near to $P$; describe the arc $pu$, and join $HV$; let $FPE$, $FPE$,
be the generating circle at P and p; and FE, f e, the diameters which pass through E, e, the points in which it touches the line DA; join CF, f P, which will be tangents to the curves at P and p. (Prop. 2, Cor. 2.) And draw the lines FE, e e, which will be normals to the curve; draw VR perpendicular to HV; also FE perpendicular to FP, and e F perpendicular to PE, and join F E.

Because EF = DV, (Prop. 2. Cor. 1.), therefore PF = VI, and in the same manner p F = H; also, supposing the tangents FP, f P, to meet in K, we have, by rejecting quantities which are infinitely small in respect of others, K F = K V, HF = H P, p F = P F = H V = H R, and PK and KP = the epicycloid arc P P; and since p F = P F = (p K + K P + F P,) = (p K + K P + F S) K F = P F = P F = F S, we have C T = P P = r S E \\

The indefinitely small triangles FP, f P, v V r, are similar; for the angles at s and r are right angles, and (considering the angle v C as coinciding with its tangent) the angle v V r is equal to the angle DH V; or to E F P, that is to F F s; therefore V F, F E, F r = s; but V F, F E, and V R = CE = d; therefore: CE = (d + 2); the corresponding increments of the arc HP; and it appears, that the chord HV and arc HP, which begin together, are augmented by increments which have to each other the constant ratio of c to 3 c + 2 a; therefore the chord HV, and arc HP themselves, will have to each other the same ratio.

Con. The arc HP, half the epicycloid, is a fourth proportional to the three straight lines, c, 2 c + 2 a, and 2 a.

Scholium 1. If the epicycloid be interior, then the chord of the generating circle determined as in the proposition, will be to the epicycloid arc as the difference of the diameters of the fixed and generating circles to the radius of the fixed circle. The proposition is demonstrated in this case exactly as in the other.

2. If we suppose the radius of the fixed circle to be infinite, its circumference is to be reckoned a straight line, and the ratio of c to 2 c + 2 a is that of c to c 2 a, or 1 to 2; that is the common cycloid; and the proposition agrees with what has been shown concerning that curve.

3. It appears that any arc s of a cycloid and epicycloid, may be rectified (that is, a straight line may be found equal to it), when the curve is described by a point in the circumference of the generating circle. When the generating point is within or without the generating circle, the rectification of the curve is reducible to that of the ellipse; and therefore cannot be effected but by approximation. See Fluxions.

Prop. IV.

The same things being supposed as in last proposition, let PE, a normal to the curve at P, meet the circular base of the epicycloid in E; and let DV, the chord of the generating circle, be drawn. The area of the space bounded by DH, the diameter of the generating circle, HV the circular arc, and VD the chord of its supplement, is to the area bounded by DH, and by HP the epicycloid arc, PE the normal, and DE the arc between the middle of the base and normal, as the radius of the fixed circle to the sum of three times its radius, and twice the radius of the generating circle.

Take p indefinitely near to P; describe the arc p v; join D v, and draw v r perpendicular to DV, and e F perpendicular to EP. And because the equal arcs V v, f F are indefinitely small, they may be considered as coinciding with tangents, and V v r, e F n may be taken as rectilinear triangles, which will be equal, because, besides the equal angles at r and n, the angle e F n is equal to E F P, and v v r to DH v = E F P; therefore e F n = v v r. And because it was shown in last proposition that r v or e n is to P p, the indefinitely little arc of the epicycloid, as c to 2 c + 2 a; therefore by composition, r v : n c = P p : c 3 c + 2 a. Now the infinitely little triangle D r v, and trapezoid n p e, have the same altitude; for D r or D v is equal to P n or p e; therefore the triangle D r v is to the trapezoid n p e as r v, the base of the former, to c 2 c + 2 a the sum of the parallel sides of the latter; that is as c to 3 c + 2 a. But the triangle and trapezoid are the increments by which the circular space D H V D, and the epicycloid space D H P E D, are augmented, in consequence of the change of position of the normal from PE to p e; therefore, these spaces are continually increased by quantities which have to each other the constant ratio of c to 3 c + 2 a; and consequently the spaces themselves have the same ratio.

Con. The whole epicycloid space D H P A D is to half the area of the generating circle as 3 c + 2 a to c.

Scholium. When the radius of the circular base is infinitely great, the epicycloid becomes the common cycloid, and the ratio of 3 c + 2 a to c becomes the ratio of s c to c, or s to 1, as was demonstrated in Prop. 8. of the Cycloid.

Prop. V.

If a thread be fastened at A, one extremity of an plate epicycloid, and applied along the curve A P H, so as to terminate at H, its middle; then, if it be unfolded, so that PX, the part disengaged, may always be extended into a straight line, its extremity X will describe another epicycloid H X Z, similar to the epicycloid A P H.

Let H V D and P F E be the generating circle, when it passes through the points H and P respectively. On C the centre of the fixed circle describe the arcs H F R and P E; join H V, and V E, and make E F to F Y as CE to C F (which is as a to 3 c + 2 a, and join XY. Because PF is equal to V H, and the arc PH to the straight line PX, PF : X P : c : 2 c + 2 a (Prop. 3.) and by conversion, PF : F X : c + 2 a, that is, by construction, as E F to F Y; hence the triangles P E F, P F X are similar; the angle F X Y is consequently a right angle, and a circle described on F Y as a diameter will pass through X, and touch the arc H R in F. Again, because the angles X Y F, P E F are equal, the arc X F is similar to the arc P E, and arc X F : arc P F : chord X F : chord P F, and X F : P F : Y F : P E (by construction) : C F : CE : arc H F : arc H E; therefore arc X F : arc P F : arc H F : arc H E; But the arc P F is equal to the arc E D, because, by the generation of the curve, arc A E = arc E P, and arc A E D = arc E P F; therefore the arc X F is equal to the arc H F; Hence it follows that the point X is in an epicycloid H X Z, of which the arc H R is half the base, and F X Y the generating circle. And because, by construction, E F : F Y : C E : C F; the diameters of the generating circles, have to each other the same ratio as the diameters of the fixed circles; therefore the epicycloids will be similar.

Con. The radius of curvature at any point in an exterior epicycloid is to the chord of the arc of the generating circle, between that point and the base in the constant ratio of the sum of the diameters of the fixed and generating circles, to the sum of the radii of the former, and the diameter of the latter. For X P is the
EPIGRAM, (from ετιο, upon, and γραφειν, to write,) originally signified merely, as its derivation denotes, an inscription, generally upon some public edifice, monument, or remarkable spot. Even among the Greek writers, however, the word epigram gradually acquired a more extensive signification, and was almost indiscriminately applied to any short poetical composition, descriptive of local scenery, commemorative of some striking event, or illustrative of some peculiar moral feeling or affection of the mind. Of such ancient epigrams or inscriptions, we have many beautiful specimens in the Greek Anthologies; and it is justly remarked by Mr Drake, in his Literary Hours, that a number of these productions bear, in their style and character, a very close analogy to the modern sonnet.

Among the Romans, the meaning of the word appears to have been much restricted; with them an epigram was usually understood to denote a short satirical effusion; and, in this sense the name has generally been adopted in modern times.

The characteristic requisites of an epigram are expressed in the following couplet:

"What is an epigram?—A dwarfish whole,—
Its body brevity—and wit its soul."

Shortness, indeed, is peculiarly essential to the composition of an epigram; when spun out to any considerable length, it loses its epigrammatic character, and must be referred to some other department of poetry. The wit of an epigram generally consists in some unexpected satirical point or allusion, which pleases us, either in consequence of the surprise it excites, or the ingenuity of the thought, or rather, perhaps, from both combined. But if we look to the origin of the term, or to the best examples of this kind of writing, in ancient and modern times, it will not appear that satire is essentially required in an epigram; indeed, many of the most beautiful specimens of this species of composition have no allusion that can be deemed satirical.

There is no British author, we believe, who, like Martial among the Romans, has distinguished himself by the composition of any considerable number of epigrams, in his native language; but the works of some of our most eminent poets abound in epigrammatic turns; and we have ample collections of the scattered effusions of our wits in this kind of writing. It is very evident, however, that we are indebted to the Greeks and Romans for a great deal of that point which is to be found in modern epigrams. See the Greek Anthologies. Bland's Translations from the Greek Anthologies. Lessing, Ueber das Epigramm. The Festival, or a Collection of Epigrams, &c. by Mr Graves. The British M Garland, Vol. 12mo. (2)

EPILEPSY. See Medicine.

EPILOBIUM. See Botany, p. 199.

EPI MEDIUM. See Botany, p. 123.

EPI ACTIS. See Botany, p. 314.

EPIRUS, was a region in ancient Greece, bounded on the east by Macedon and Thessaly; on the south by the Ambracian Gulf; on the west by the Ionia Sea; and on the north by the Ceraunian Mountains. It consisted anciently of three divisions: Chaonia, lying towards the north; Molossis, the middle or inland province; and Thesprotia, extending on the south from the Ambracian Gulf to the sea. Many cities of considerable magnitude adorned this territory, of which we shall only mention Ambracia, built near the mouth of the Arachthos, which was about three miles in circumference, and became the residence of the Eacidae, who reigned in Epirus; and Dodona, said to have been founded by Deucalion as early as the flood, and rendered illustrious by the temple and oracle of Jupiter Dodonaeus, which were accounted the most ancient and venerable in all Greece. The lands which stretched along the sea coasts were fertile and well cultivated; but the interior parts were covered with vast forests, and were almost entirely barren. The horses of Epirus were famous from the most remote antiquity; and the dogs, which the Romans called Molossi, from the district where they were reared, were every where purchased and employed in hunting.

If credit be due to Josephus, Dodanim, the grandson of Japhet, having first settled in the island of Rhodes, either went over to the continent himself, or sent thither some of his descendants, to people this region. From him the inhabitants were called Dodonians, and their principal city Dodona: but in a short time after, a number of different tribes migrated thither, and took possession of those places which were not yet occupied. Having no bond of union, they were almost constantly engaged in war; and though this inspired them with the most called courage, it rendered the introduction of civilization and refinement slow and difficult.

During the time that the country was divided into a number of independent states, each governed by its own king with the most despotic authority, the history of this region is altogether unworthy of attention. It was only when the kings of Molossis had gained the ascendency over their neighbours, and had reduced the whole under their sway, that this region was denomina- tion Epirus, from a Greek word which signifies the con- tinent. Pyrrhus, the son of Achilles, was the first of the race of the Eacidae, who assumed the sceptre. But though the ancient annalists generally begin the history of this country with his accession after the siege of Troy, yet the exploits which they attribute to him, are certainly disfigured by poetical invention. The names of his descendants, who governed Epirus till the Persian war, are buried in oblivion. When Xenexes invaded Greece, Admetus held the sceptre; but as he had refused to assist either party, Themistocles, after the termination of the war, rejected, with disdain, his offers of alliance; but when that celebrated Athenian was banished from the ungrateful country, which his skill and
bravery had saved, he found an honourable asylum in the
court of the prince, whom he had formerly contemned.

He was succeeded by his son Tharybios, who went
to Athens for the sole purpose of conveying the literature
which was there cultivated, to his own country, and
who, on account of the wise laws which he after-
wards enacted, was enrolled among the ancient law-
givers. His descendants, Alcetas, Neoptolemus, Ar-
bas, Alexander, Accedes, Alcetas II. reigned in suc-
cession.

Our attention, however, is powerfully arrested by
Pyrrhus II. the son of Accedes, who, when an infant,
had been saved from the fury of the rebels, who drove
his father into exile. This prince, nursed by misfor-
tune, and educated amid dangers in a foreign land,
was seated upon the throne of his ancestors by Glau-
cius, king of Illyricum; was afterwards stripped of his
dominions by Neoptolemus, his great uncle; and was
then sent by his brother-in-law, Demetrios, with whom
he lived in exile, as a hostage to Ptolemy, king of
Egypt. Having conciliated the affection of that mon-
arch, by his assistance he again ascended the throne of
Epirus; joined the Tarentines in a war which they
waged with the Romans; embarked a powerful army
for Italy, and, after encountering a dreadful tempest,
arrived at Tarentum. Taking the field at the head of
his own forces and those of his allies, he defeated the
Romans upon the banks of the Sisir; but whilst he
poured his victorious army over the territories of his
enemies, he was completely routed upon the plains of
Asculum, where he was dangerously wounded. Col-
lecting the relics of his forces, he again encountered the
Romans near Beneventum; but, after the greatest
part of his army had fallen around him, he was obliged,
not only to leave the field of battle, and retire to Ta-
rentum, but to abandon Italy, and return home. To
retrieve his reputation, and supply his exhausted trea-
sury, his restless spirit then invaded the kingdom of
Macedon, overthrew Antigonus in a pitched battle,
drove him from his throne and his dominions, and took
possession of the kingdom. Fired with success, and
with the hope of still greater conquests, he burst into
the Peloponnesus with a mighty army; but the brave-
ness of the Lacedaemonians arrested his progress: and
having lost his son, and avenged his death, in a bloody
but undecisive engagement, he directed his march to
Argos, and, by stratagem, made himself master of
that city. But Antigonus, with an army which he had
collected, and Arcus with his Lacedaemonians, who had
closely pursued him, entered the city during the night,
immediately attacked his unsuspecting army, and the
morning discovered the terrible carnage which their fury
and revenge had made. Pyrrhus, who now per-
ceived that all was lost, endeavoured in vain to retire
from the city with the wreck of his forces; and, whilst
he performed prodigies of valour, a woman who sur-
veyed the battle from the top of a house, beheld the
enraged monarch below her ready to plunge his sword
into the breast of her son, who had wounded him, and,
in order to prevent the blow, she threw furiously a tile which
she had rent from the roof, upon the head of Pyrrhus,
which, falling him to the ground, saved her son, and
avenged her country. The head of the monarch was
severed from the body, and the remains of his army
were made prisoners.

The kingdom, after his death, was successively go-

derned by Alexander II., Ptolemy, Pyrrhus III., and
Deidamia. But though this princess succeeded her fa-
ther, a female hand was too weak to keep her fierce and
turbulent subjects in subjection; a conspiracy was
formed against her, and in the temple of Diana, to
which she had fled for refuge, she was barbarously mur-
dered. The Epirotes then formed themselves into a
republic; but instead of avenging, by their future
valour, that liberty which they had shamefully pur-
chased, they gradually sunk from the proud station
which they formerly occupied, and became subject
to the king of Macedon. But when the Macedonians
under Philip yielded to the superior destiny of the Ro-
mans, the Epirotes received their liberty from the ge-
nerosity of the conquerors. To free themselves from
the debt of gratitude, they entered into an alliance with
Perseus the son of Philip, against their benefactors, and
endeavoured to prop the power which had long oppres-
sed them. The magnitude of their ingratitude, how-
ever, was equalled by its punishment. After sharing
in all the adverse fortunes of Perseus, the authors of
the war beheld Paulus Emilius, with an exasperated
army, enter their territories; divide among his daring
veterans the wealth which had been amassed for ages;
level in the dust the cities which their fathers had de-
corated; condemn to slavery a hundred and fifty thou-
sand of the wretched inhabitants; and transport the
chief men of the country to Rome, and to perpetual
imprisonment. The glory of Epirus was now for ever
extinguished. When the Consul Mummius had redu-
ced Corinth to ashes, and dissolved the Achaian league,
Epirus became a Roman province. In this state of de-
gradation it remained till the division of the Roman
world, when it shared the fortunes of the eastern em-
pire. But when the French and Venetians, under the
Marquis of Monserrat, had stormed Constantinople, and
divided the Greek provinces, Michael, a bastard of the
house of Angelii, fled from the camp of the Latins, and,
seizing upon Epirus, Actolis, and Thessaly, laid the
foundations of a powerful dynasty, and claimed the
honours of an independent throne. Theodore Ange-
lus succeeded to the power and ambition of his brother;
took prisoner Courtenay, who had been elected emperor
of Constantinople, and had invaded Epirus, expelled
Demetrios from his kingdom of Thessalonica, and as-
sumed the lofty appellation of Emperor. This dawn
of glory was soon overcast. Amurath II. having driven
his descendants from Epirus, bestowed the dependant
sovereignty upon the family of the Castriots, who go-
\n
An epitaph ought to be short and simple, containing
merely the name, and a brief character of the deceased.
In the case of persons of great eminence and notoriety,
the name, perhaps, is of itself almost sufficient; but if
the individual be of less note, some more ample desig-
nation is requisite. Laboured characters, however, and exaggerated representations of merit, are misplaced on a tomb-stone; to real worth and dignity they give no additional elevation; and, when joined to insignificant names, they are apt to excite very opposite feelings from those intended to be produced in the mind of the reader. The form and tenor of every epitaph ought to be solemn and impressive; the introduction of any ludicrous expression or allusion, in such a situation, must excite disgust.

For a character of the style best adapted to this kind of composition, we refer our readers to Dr Johnson's Essay on Epitaphs, where they will also find a minute criticism on the epitaphs of Pope. (c)

EPITRITES, in music, is an interval whose ratio is $\frac{254}{245}$ or $\frac{5}{4}$, and is the Fourth Minor; which see.

EPIZOOTY, derived from επί and ζώος, signifies a plague or murrain among animals. In the common acceptance of the term, murrain is limited to distempers among useful and domesticated animals, whereas epizooty comprehends those pestilential ravages to which the whole living creation is liable.

The frequent recurrence of distempers among the domesticated animals which form the principal subsistence of mankind, has attracted particular attention to their origin, progress, and the means of cure, or of averting the danger. At present, however, we shall chiefly restrict our remarks to some historical notices of the more singular and decided epizooties which have threatened the extinction of animals in different countries.

On ascending to the most ancient periods of history, we discover a destructive epizooty in one of the plagues of Egypt, extending to all domesticated animals. This is described by Moses in unequivocal terms, "Behold, the hand of the Lord is upon the cattle which are in the field, upon the horses, upon the asses, upon the camels, upon the oxen, and upon the sheep; there shall be a very grievous murrain;" and there is one remarkable peculiarity indicated here, which identifies it with later epizooties, as being "a boil breaking forth with blains upon man and upon beast." It has further been exemplified, that the plague among mankind is frequently accompanied or followed by an epizooty.

Omitting the accounts of ancient poets who treat of such distempers, we find several allusions to destructive epizooties, in the writings of authors, long preceding the Christian era. Plutarch speaks of an epizooty in the time of Romulus, as a great mortality of men and beasts in Italy, when they perished almost immediately on the attack. Dionysius Halicarnassus and Livy, particularly the latter, describe epizooties, followed by pestilence, at different intervals of the fifth century anterior to Christianity, also in Italy. Livy likewise relates, that immediately after the capture of Agrigentum by Marcellus, in the year 212 before Christ, mankind and animals were alike the victims of a pestilential disorder; and if we could trust to Silius Italicus, the symptoms of it might be described.

In the earlier centuries of the Christian era, repeated instances of epizooty are found in the works of the ancients. Tacitus speaks of a terrible mortality among mankind and animals, arising "without any sensible intertemperance of the weather," which swept off all ages indiscriminately, in the year 68; and the Roman territory was ravaged by a similar pestilence about the year 190.

In the fourth century, we learn that the means adopted to avert a general epizooty in Europe, was marking all animals on the forehead with a red-hot iron in form of a cross; and the violence of this remedy probably produced that efficacy which is ascribed to it. Vegetius Renatus, who flourished in the same century, suggests various cures for the different pestilential disorders of cattle.

Descending still lower, many examples of epizooty are found in contemporary authors; and it has been remarked, that "in the interval between 810 and 1316, a period of darkness, horror, and calamity, history characterizes not less than twenty epizooties, more or less destructive, which ravaged different parts of Europe." Of these, five or six attacked cattle, two horses, and twelve animals in general. Four were likewise destructive of mankind.

Hitherto, all information concerning such diseases, had consisted in brief remarks and notices on the simple existence of the malady; but, in the sixteenth century, the subject was examined with more attention. Fracastorii, an Italian physician, witnessed an epizooty among cattle in the year 1514, which first appeared in Frioul, whence it spread by contagion to Venice, and from thence to Verona. A similar pestilence raged among sheep in France during the following year, and both are described as an eruptive fever, narrowly resembling the small-pox. Few characteristics are preserved, except that it was extremely contagious, and that the animals which exhibited no eruption perished. However, on the re-appearance of that or another malady in 1578, it was more plainly designated small-pox, and apprehensions were some time after entertained, that man might be liable to infection. The Venetian government, therefore, on an universal dysentery attacking the citizens of Venice and Padua, issued an edict in 1599, prohibiting the sale or distribution of the flesh of cattle, or milk, butter, or cheese, under pain of death. It had likewise been observed, that such distempers proceeded from the east, and that some diseased cattle had been brought from Hungary and Dalmatia, where the malady became so common, that another market was sought out for the two cities.

In 1661, after a hot, dry summer, a kind of phrenzy spread among animals, especially horses, cattle, and sheep; but we do not know if it was contagious. It was primarily confined to the northern climates, and, on opening the head, one or more worms were found in the substance of the brain. Numbers of fasciolous or intestinal worms, were also discovered in many animals perishing by an epizooty in 1663 and the two succeeding years, and were then considered the sole cause of the distemper. Analogous symptoms, though it does not appear whether the malady was equally fatal, attacked almost the whole cattle in the Danish territory in 1674.

France was visited by an epizooty among the black cattle in 1682. The animal functions were uninterrupted until the attack, when sudden death ensued. This was accompanied by gangrene of the tongue and intestines, and the former sometimes came away in pieces. Those who tended the cattle, and neglected proper precautions, are said to have been infected by the disease, and to have died. Its progress was regular, and marked by astonishing rapidity; and it was observed to be at the rate of 12 English miles in 24 hours. Thus it spread from the frontiers of Italy to Poland.

The knowledge of the various distempers to which animals are subject, had wonderfully increased in the commencement of the eighteenth century; and opper-
tunities for observation seemed to keep pace with a general anxiety to investigate their cause. Between the years 1705 and 1711, a distemper called the flying chancre or bubo, which the latest authors denominate a real plague or murrain, was found to be making terrible ravages in Europe. It had been imported by a single infected ox brought into the Venetian states from Hungary and Dalmatia; and it was thence disseminated throughout the Roman territory and the kingdom of Naples, sweeping away almost the whole cattle in its progress. It did not reach France until the year 1714; and, in the same year, having been some time prevalent in Britain, the most vigorous means for preventing it were adopted by government. All the animals attacked were ordered to be destroyed, and buried deep in the earth, and a compensation allowed to those who thus lost their property. The violence of the disease did not subsist above three months, during which time the counties of Essex, Middlesex, and Surrey, lost 3857 cattle, old and young. At this time it was observed, that on cows being brought to a pond to drink, many became giddy, fell down in convulsions, bled copiously at the mouth and nose, and died. Other nations suffered more severely; Piedmont lost 70,000 cattle; Holland, not fewer than 200,000; and the full extent of the epizooty throughout Europe, was calculated to have destroyed 1,500,000 animals. All these perished of the infection disseminated by the single diseased ox from Hungary. But the disease was marked by considerable distinctions in different countries; and it seems that some of its symptoms bore little resemblance in one place to what were seen in another.

An intelligent German physician, Andrew Goelcke, had an opportunity of making many interesting observations on an epizooty among black cattle in 1730, which spread by contagion; and the attention of M. De Sauvages of Montpellier was soon afterwards directed to a distemper among cattle, horses, mules and asses. This was a blane of the tongue, degenerating into a cancerous ulcer, whereby that organ was almost totally destroyed. The commencement and termination of the disease were sometimes witnessed within 24 hours. The people of the city of Nismes did not escape; and on looking into historical record, several Parisians had apparently been affected by a similar complaint, in the year 1571. The tongue of the diseased animals now fell to pieces, while they fed and performed their ordinary functions.

One of the most destructive epizooties known to have appeared, again ravaged Europe, but for at least ten consecutive years from about 1740. Its virulence, however, was greatest in 1745 and 1746. It was generally thought to have originated at the siege of Prague, and to have been disseminated from Bohemia by means of distempered cattle. This disease was exhibited by the same general symptoms of shivering, palpitation of the heart, difficult respiration, a frequent cough, coldness of the hoofs and horns, cessation of the natural evacuations, and sometimes the animal fell down as it struck by apoplexy. Eruptions covered those which survived the violence of the attack. But it was evidently contagious, and the strongest precautions were adopted to repress the infection. Former experience had proved, in the history of an epizooty, by Lancisi, that they could not be too strictly adopted; for certain drivers having brought their cattle to a fair in Italy, in the year 1718, a prohibition was issued against holding it, in order to prevent the dispersion of the cattle. However, the drivers rather than be disappointed of a market, conducted them by private roads to Rome, and sold their cattle at a low price. Immediately afterwards, a contagious distemper spread throughout the whole Roman territory, and destroyed 500,000 animals. Notwithstanding similar precautions now enforced, and burying the diseased cattle, as well as interdicting the sale of their flesh, untoward accidents happened; and if we are to credit the accounts of the times, contagion was disseminated by the skin. But at different places in France, guards were posted to prevent cattle from approaching them, whereby the stock was preserved in health, though the malady was making rapid advances in the surrounding country. The Marquis de Courtrinon instituted numerous experiments regarding this distemper, from which he concluded that it exhibited itself on the fourth day from infection, that the ninth was its crisis, and that the contagion could spread only by direct communication between two animals.

Whether this epizooty totally ceased within ten years, or, indeed, whether it has ever been completely extinguished, may be the subject of dispute. Perhaps the renewal of epidemics is judged to be such, only because observations are not sufficiently extensive to prove that they are always subsisting. In the course of the year 1716, a new remedy, inoculation, had been attempted at Brunswick, and in an epizooty which appeared in Holland during 1755, the same remedy was repeated, though with little success, and recommended in Britain by Dr Layard, in the year 1757. The distemper in the latter country was considered absolutely similar to the small-pox; and the infection was said to have been brought from Holland by two white calves of a favourite breed, or by two skins of diseased animals.

Whatever was the case, many cattle perished of it.

Different epizooties appeared about the same time among the cattle, horses, and reindeer of France, Austria, Finland, and Lapland. Swine, dogs, and even poultry, are said to have been attacked by it. Russia did not escape; and, if we can credit the relations given, the malady was propagated by the skin of an infected bear, even to the destruction of mankind. These epizooties were either perpetuated or renewed during the years immediately subsequent, and, if possible, raged more extensively among the various genera of animals. The horses of Switzerland, the cattle of other countries, sheep, and particularly lambs, were swept away in thousands. In 1764, dogs were attacked throughout France, poultry in Spain, and the rest of the feathered tribes all over Europe. The milk of infected cows spread the contagion; for those animals supplied with it were covered with pustules; and people who suffered in the same manner experienced great difficulty of deglutition, and burning heat in the throat.

For some years, about this period, an epizooty raged among the black cattle of Holland. It first manifested itself in the province of Groningen, especially in the village of Haren, and spreading insensibly, carried off the whole cattle belonging to a neighbouring district. Its attack was announced almost at once by the animal becoming dull, and rejecting drink. Fever and shivering, attended by a general prostration of strength, followed; the ears and horns grew cold; a cough became unremitting; a purulent matter was discharged from the nose, and an ichorous fluid flowed from the eyes. The hide was puffed up, and a crackling, like that of parchment, was heard on pressure. Some were attacked by diarrhoea, others by constipation from the fourth to the sixth day of the disease, and they died from the second to the eleventh day after its commencement. The blood of the animals then proved thin; the intestines inflamed.
and putrid; the lungs gangrenous; the gall bladder always greatly enlarged; and many fascicule were in the liver. The symptoms were generally the same; and Camper, who strictly watched the appearance, progress, and issue of the malady, pronounced it a contagious putrid fever. Animals once attacked were never liable to its recurrence, or at least very rarely; hence Camper, from that and other circumstances, concluded, that, to repress it, four principal objects were to be kept in view. 1. To clear the air to prevent the malady, and abate its virulence. 2. To preserve the fluids from corruption. 3. To preserve the strength of the animal. 4. To cleanse the intestines immediately on the appearance of the disease.

It is unnecessary to enter on any detail concerning these different principles; but respecting the first, in Camper's opinion, there was no means of guarding against contagion, but by excluding diseased animals, and all substances by which infection might be communicated. He also conceived that inoculation was the most probable method of averting the malignity of the distemper. He was not discouraged by the doubtful issue of former experiments, and even repeated them on a more extensive scale. His first essays, which he did not consider particularly successful, saved 46 out of 112 infected animals; again, 46 were preserved out of 92; and, if cows were not far advanced in gestation, three-fourths survived the malady by inoculation. Notwithstanding this naturalist's anxiety to proceed still more extensively, it was found impracticable to persuade the principal animal dealers of the expediency of artificial inoculation, whence the system of inoculation was soon brought to a close. It has nevertheless been successfully practised elsewhere, particularly in Denmark; and in the first three years of the experiment, less than a sixth part of the infected cattle was lost. Strong prejudices, perhaps they can scarcely be called imprudent, were opposed to the same proposal in England, when an inoculator applied to the privy council for permission to carry the various matter from Hampshire into other counties. It was then remarked, that the introduction of a disease where it did not exist, might spread by contagion beyond the power of experiment to cure, and that it was already known the malady might be exterminated by killing the cattle. Camper established several important points: such as, that the epizooty imparted by inoculation, was exactly similar to that communicated by natural infection; that it was of a much milder nature; as also, that animals infected in this way, resisted both natural contagion and the consequences of inoculation. The malady proved extremely destructive in Holland; for it appeared, that of 286,647 animals attacked, not few than 208,354 died.

The same disease seems to have made its way into Picardy, by the introduction of a diseased cow, as was supposed, from the Low Countries, in the year 1771; and after being subdued, broke out with redoubled violence in 1773. Its first and principal ravages were in the province of Hainault and Picardy, whence it became widely extended. Numerous remedies were tried, but their inefficacy being proved, the extinction of the malady was sought in the destruction of the infected animals. This disease, after minute observations by many intelligent persons, was identified with that which had been so fatal in the years 1711 and 1743, and though different symptoms were exhibited in the animals attacked, it was as before judged to be the same in all. But Vieig d'Azur now made experiments, tending to establish, that inoculation was not an effectual antidote; and this result is said to have coincided with the experiments of the Marquis de Courtrivon some time before. The British government adopted the precaution, of ordering all infected cattle to be killed by strangulation, and without effusion of blood; that their carcasses should be buried deep in the earth, with the hide entire; and that all fodder, litter, and every thing else, which might communicate the contagion, should be buried along with them. Similar ordinances were promulgated by the government of France, and renewed for several years, strictly enjoining the destruction of the diseased animals, and that their carcasses should be buried, and their skins cut in pieces, in order to prevent any dealings for them. Indemnification was promised to those who thus lost their property, and a premium offered to whoever should substitute horses or mules for cattle in agricultural operations. By these and other prudent regulations, this, which is one of the epizooties best characterized in history, was repressed.

During the period that contagious distempers swept away the cattle of Europe, a malady even more rapid in its progress appeared among those of the West Indies. Its effects seem to have been more minutely traced in Guadaloupe, where it first attacked black cattle, then spread to horses, and is said even to have affected man. Animals apparently well, in good condition, and feeding as usual, were suddenly seized with shivering fits; attended by convulsions in the spine and abdomen, which sometimes carried them off in an hour. Almost all the negroes who opened the dead cattle, had boils rising on their arms, attended by much fever; and those feeding on their flesh, experienced the like symptoms. But examples were given of several, who actually died from infection of the distemper. Something similar was witnessed in France, where persons skimming the animals, themselves died of the contagion, the effects of which were immediate.

Between the years 1780 and 1790, a pestilential disease prevailed among the cattle in the northern counties of Scotland, vulgarly denominated hasty, from the rapidity of its progress. The animal swelled, its respiration was affected, there was a copious flow of the eyes, it lay down, and sometimes expired in a few hours. This distemper was ascribed, as has been the case in many foreign countries, to the damp and shaded pasturage of copses, and with the decay of the wood the epizooty has declined. The peasantry attempted to cure the infected animals, and prevent contagion of the healthy, by fumigation with the smoke of neet fire, which was fire obtained by the friction of a certain wooden apparatus erected on an islet.

The eastern parts of Asia were visited by a destructive epizooty among the horses, especially in 1804; and after the severity abated in 1805 and 1806, it was renewed with uncommon virulence in the year 1807. In so far as we can learn, this distemper consisted of a sudden swelling, attended by shivering fits, an abscess formed most commonly in the head, and the animal died in twelve hours at farthest. But, in many instances, its commencement and termination were infinitely more rapid, and death was known to ensue in half an hour. The malady was observed early at Ochotsk. Cattle, reindeer, and horses, all suffered; and of the last, a caravan consisting of eighty, preserved only ten. The Russian government of those distant regions, in order to repress the disease, ordered all the animals perishing of it to be burnt; but before its nature was well understood, the Jakutchians, to whom horse flesh is grateful, unwilling to lose such a source of subsistence, fed
equal-beating.

But Earl Stanhope in 1806, was the first we believe

who proposed to use a succession of equal-beating concords of the same kind, in the tuning of musical instruments. A controversy on this subject, which ensued in the Philosophical Magazine, to which we have alluded in our article Bi-EQUAL. Third, gave an interest to this latter species of equal-beating concords, which led to the discovery of some beautiful theorems relating to them by Mr John Farey, and we are happy in having it in our power now to lay them before the public for the first time.

Any number of tempered concords of the same name and kind, i.e. all flattened or all sharpened, may be so tuned above each other, and beat equally quick, that the compass or interval of the whole, or the lowest and highest sounds, may be given ones; for put

\[ l = \text{the number of equal-beating concords to be tuned;} \]

\[ \frac{n}{m} = \text{the ratio of each of these concords when perfect;} \]

\[ b = \text{the number of beats in 1″ of time;} \]

\[ \frac{r}{s} = \text{the ratio of the given interval or compass; and} \]

\[ N = \text{the number of complete vibrations in 1″, made} \]

by the lowest given sound thereof; and we have

Theorem I.

\[ N \times \left( \frac{\frac{n}{m} - \frac{s}{r}}{\frac{n}{m}} \right) \]

the series terminating, when the index of \( n \) becomes negative, \( n \) and \( r \) being the least terms (in their lowest terms) of the ratios, and accordingly as \( b \) is positive or negative the beatings will be sharp or flat.

Also, if \( V = \text{the number of complete vibrations in 1″} \)

of the note arrived at, after tuning \( t \) of such equal-beating concords in succession; then,

Theorem II.

\[ V = \frac{(Nm^\pm b \times (m^{\pm 1} + n^{\pm 1} n^{\pm 1} + \&c.))}{n^5} \]

the upper or lower sign being used, according as \( b \) is positive or negative, or the concords greater or less than perfect.

And if \( \frac{c}{d} = \text{the ratio of the last or uppermost of} \ t, \text{of such equal-beating concords in succession, then} \]

Theorem III.

\[ \frac{c}{d} = \frac{(Nm^\pm b \times (m^{\pm 1} + n^{\pm 1} + n^{\pm 1} n^{\pm 1} + \&c.))}{(Nm^\pm b \times (m^{\pm 1} + n^{\pm 1} + n^{\pm 1} n^{\pm 1} + \&c.))} \]

Example 1. If Earl Stanhope's two equal-beating bi-equal major thirds E\( \mathbf{b} \) and B\( \mathbf{c} \), are to be tuned in the minor sixth E\( \mathbf{c} \), in the octave above tenor cliff C, we have, in Theorem I, \( t = 2, n = \frac{4}{5}, r = \frac{5}{8}, \text{and} N = 300, \)

\[ 300 \times \left( \frac{\frac{8}{5} \times 16 - 25}{4 + 5} \right) = 300 \times \frac{8}{9} = 20, \]

the number of beats sharp, made in 1″ by each of these new thirds, as observed in the Phil. Mag. vol. xxx. p. 4, and in our article CONCERT Pitch. In order to find the vi-
brations and ratio of the intermediate note \( b \Lambda \), we have in Theorem II. when \( t=1 \), \( b=20 \), and the rest as before; and hence
\[
V = \frac{300 \times 5 + 20 \times (1 + 0)}{4} = 1500 - 20 = \frac{380}{16} = 23.625 
\]
the<br>brations of \( b \Lambda \); and \( \frac{300}{380} = \frac{15}{19} \) is the ratio of \( E b \Lambda \). And in order to obtain the ratios of these bi-equal thirds, we have in Theorem III. first, \( t=1 \), \( b=20 \), &c. and
\[
\frac{c}{d} = \frac{4 \times (300+0)}{4 \times 300+20} = \frac{1200}{1520} = \frac{15}{19} = \text{the ratio of } E b \Lambda , \text{ as before; and second, } t=2, &c. \text{ and } \frac{c}{d} = \frac{4 \times 1520}{750+180} = \frac{19}{24} = \text{the ratio of } E c. \text{ Or these same ratios might have been got, by inverting the vibrations of the notes already found: thus } \frac{300}{380} = \frac{15}{19} ; \text{ also } 300 \times \frac{8}{5} = \frac{480}{1} , \text{ the vib. of } c \text{, and } \frac{380}{480} = \frac{19}{24} \text{, which, as before, are his Lordship's two new thirds, mentioned in our article Bi-equal Third. The minor sixth } C b \Lambda \text{ is } \frac{12}{19}. \]

Example 2. If it be required to tune his Lordship's three equal-beating tri-equal Quints, in the major thirteenth \( G e \), (in the middle septave, and partly above and below it,) we have, \( t=3 \), \( n \frac{m}{m} = \frac{2}{3} \), \( r = \frac{3}{10} \), and \( N = 180 \); and Theorem I. gives
\[
\frac{b}{b} = \frac{180 \times \frac{10}{3} \times \frac{8}{27}}{9+64+4} = 60 \quad \text{or } 3.1578947 \text{ flat beats per } \frac{1}{2} \text{th, yielded by each of these three consecutive fifths. See Phil. Mag. vol. xxvii. p. 13. In Theorem II. make } t=1, b = 60, \frac{r}{r} = \frac{19}{19} \text{ and the rest as before, and } V = \frac{180 \times 3 - \frac{19}{19} \times (1+0)}{2} = \frac{5100}{19} = 268.910526 \text{ vibrations per } \frac{1}{2} \text{th of the note } D \text{. See Phil. Mag. vol. xxx. page 5. In like manner, when } t=2, \text{ we get } \frac{7620}{19} = 401.0526316 \text{ vibrations of the note } A \text{. If the value of these three tri-equal quints be required, they may be had by Theorem III.; or from their vibrations thus, } \frac{180 \times 19}{5100} = \frac{57}{85} = \text{GD}; \text{ also } \frac{5100}{7620} = \frac{85}{127} = \text{DA}; \text{ and the vibrations of } c \text{ being } \frac{10 \times 180}{3} = 600, \text{ we have } \frac{7620}{19 \times 600} = 190 \text{ =vib. of } A c \text{.}
\]

Example 3. If three equal-beating major thirds be required to be tuned in an octave above tenor-cliff \( C \), we have, \( t=3, \frac{n}{m} = \frac{4}{5}, \frac{r}{s} = \frac{1}{2}, \) and \( N = 240 \), which in our 1st Theorem gives
\[
\frac{b}{b} = \frac{240 \times \frac{2}{1} \times \frac{64}{125} = 125}{25+20+16} = \frac{720}{61} = 11.80328 \text{ times sharp, the rate of each of their beating. In Theorem II. } t=1, \text{ &c. and } V = \frac{240 \times 5 + 720}{6} = \frac{18480}{61} = 302.95082, \text{ the vib. of } E \text{; and } 2d, \text{ when } t=2, \text{ &c. } V = \frac{23280}{61} = 381.63934, \text{ those of } b \Lambda \text{. The ratios of these two notes will be found } \frac{61}{77} \text{ and } \frac{61}{97} \text{ respectively; and the values of these three new thirds}
\]

Example 4. If four equal-beating minor thirds be wanted in the octave as above, we have \( t=4, \frac{n}{m} = \frac{5}{6}, \frac{r}{s} = \frac{1}{2} \), and \( N=240 \); and \( b = \frac{216+180+150+125}{671} = 3.1645350 \text{ beats flat per } \frac{1}{2} \text{th, and putting } t=1, \text{ &c. in Theorem II. we have } V = \frac{191040}{671} = \frac{284.70939 \text{ vibrations of } b E; \text{ also by making } t=2, \text{ and } t=3, \text{ we get } \frac{227040}{671} = 338.36066 = b G, \text{ and } \frac{270240}{671} = \frac{402.74217}{A} \text{ vibrations. The notes themselves will be found } b E = \frac{671}{796}, \text{ } b G = \frac{61}{86}, \text{ and } A = \frac{671}{1126} \text{; and the four equal-beating minor thirds will be as follows, viz. } C b E = \frac{671}{796}, b G = \frac{916}{478}, \text{ and } A = \frac{563}{671}. \text{ If, in order further to exemplify the use of our 3d Theorem in finding the last of these thirds, we put } t=4, \text{ and } \frac{11040}{671}, \text{ &c. we have}
\]

\[
\frac{c}{d} = \frac{5 \times \left( \frac{240 \times 216}{671} \times 2 \right) - 11040}{240 \times 1296 - \frac{11040}{671} \times (216+180+150+125)} = \frac{563}{671} = A c, \text{ as before.}
\]

Example 5. Suppose it were required to calculate how many beats must be given to each of 12 successive fifths within 7 octaves above tenor cliff \( C \), we have \( t=12, \frac{n}{m} = \frac{2}{3}, \frac{r}{s} = \frac{1}{2} , \) and \( N=240 \); and in the 1st

Theorem we find
\[
\frac{b}{b} = \frac{240 \times 3 - \frac{105459}{105459} = -3.2554021, \text{ the flat beats per } \frac{1}{2} \text{th of each of these duodeci-equal quints. Make } t=1, \text{ &c. and, in Theorem II. we have,}
\]

\[
\frac{240 \times 3}{105459} = \frac{37797168}{105459} = \frac{338.3722989, \text{ the vibrations of } G \text{; and by next making } t=2, \text{ we get } V = \frac{565201080}{105459} = \frac{535.9074744, \text{ the vib. of } d \text{; and thus by taking new values of } t, \text{ all the other notes of such a system may readily be found, and the ratio of each fifth.}
\]

In a letter (which the writer has before him) from
Mr Thomas Elliot, organ-builder and tuner, of Tottenham Court, London, addressed to Dr Callcott, in 1807, respecting his attempts to tune Earl Stanhope's system, Mr Elliot proposes, as another mode of tuning, to adjust four equal-beating fifths in a true major third (and two octaves follow in the process) above tenor-cliff C; thus, CG, gD, DA, and aE. This falling of octaves, as it becomes necessary in order to keep within the octave selected for the "foundation," as it is called, might be introduced into our General Theorems above, but would too much complicate them. A less general method has therefore been used in finding the following, viz. Mr Elliot's quadruple equal quintus must each beat flat 2.016806 times per 1'; and G will vibrate 333.981597 times, D = 266.352949, and A = 401.345399 times per second.

Earl Stanhope, in the controversy above alluded to, has mentioned another species of equal-beating concords requiring three notes to be sounded at the same time, forming two tempered concords; his two bi-equial thirds, for instance, between the notes E, B A and C, so adjusted, that there shall be no beatings between the two; that is, that the beatings of E B A and B A C shall either be exactly equal, (as in our first example,) or one exactly be some concordant multiple, as 2, 4, 8, &c.

or \( \frac{3}{2}, \frac{4}{3}, \frac{5}{4}, \frac{5}{6}, \frac{8}{7} \), of the other, in a given time. See the Philosophical Magazine, vol. xxxiii. p. 297. (4)

EQUAL Harmony, has, by one class of musical writers, as Mr Emerson, Mr Cavallo, Mr Chambers, &c. been applied to the equalization of the harmony of the 12 keys, or systems of eight notes, above every finger-key of the organ or piano-forte, considered as a key-note; which system is, however, more commonly, and ought always to be the denomination, the equal temperament, or Isometric system, and by another and more correct class of writers, as Dr Robert Smith, Dr Robinson, &c. the term equal harmony, has been restricted to the attempt, to attain the scale so, that all the concords, (except the unisons and octaves, which are kept perfect,) may be equally and the most harmonious, within a given compass of notes.

Dr Smith, in his valuable Harmonics, a work undeserving of the censures that have been heaped upon it, has endeavoured to lay the foundation for such a system as has been last mentioned, on his important investigations of the theory of short cycles and beats, and, by means of which, this author concludes, (pp. 118, 259 and 263,) that pairs of "imperfect consonances are equally harmonious, when their temperaments have the inverse ratio of the (respective) products of the terms of (each of) the perfect ratios of the corresponding perfect consonances." And, by help of arithmetical and harmonical mean proportional, among the several temperaments of such pairs of consonances, collected in those several parcels, composed of Vths, VIIths, and IIIIs, and their compliments to, and compouds with VIIIs, Dr Smith's investigations lead to the conclusions, that

A system of equal-harmony, in one octave, must have its concords V, VI, and III, tempered, \( \frac{8}{5} \) (or \( \frac{5}{3} \)) or \( \frac{5}{3} \) (or \( \frac{3}{2} \)) in parts of a major comma, or nearly as follows, viz.

| -101 | +57 | -44 |
| -360 | 360' | -360' |

or those tempered concords, are \( V_{-3.08832} \), \( VI + 1.79395 \), and \( III - 1.54542 \).

In two octaves, the same will be very nearly

| -9 | +5 | -4 |
| 32' | 32' | 32' |

or \( V_{-3.09596} \), \( VI + 1.71998 \), and \( III - 1.87596 \).

In three octaves, these temperaments will be very nearly

| -5 | +3 | -2 |
| 18' | 18' | 18' |

or \( V_{-3.05774} \), \( VI + 1.83464 \), and \( III - 1.22309 \).

and,

In four octaves, the temperaments will be nearly

| -11 | +7 | -4 |
| 40' | 40' | 40' |

or \( V_{-3.02716} \), \( VI + 1.92637 \), and \( III - 1.10076 \).

For various reasons, Dr Smith preferred his three-octave system to any of the others; and in his work will be found ample tables of beats, and directions for correctly tuning it, upon a proper instrument having 21 strings, at least in each octave, such as he contrived for the purpose; and since then the patent piano forces and organs of Mr David Looeschman, having 24 sounds in the octave, can, with still greater facility, be used for this purpose; and, indeed, such improved instruments are necessary for giving correct effect to any system of temperament, except the Isometric, to which alone the defective instruments in common use, having only 12 sounds, are correctly applicable.

Dr Smith shews, that his system of equal harmony in three octaves, when tempered as above, has very nearly an equality of beating \( \frac{5}{3} \) and \( \frac{8}{5} \), between the Vths and the VIIths to the same base respectively; he also mentions, at page 220, that the same differs but little from a system wherein the major third, and the major sixth are equal-beating to the same base, the former \( \frac{5}{3} \) and the latter \( \frac{8}{5} \). Mr Farey has shewn in the Phil. Mag. vol. xxxvi. p. 51, that the temperaments in this case, by ultimate ratios, are

| -2 | +1 | -1 |
| 7' | 7' | 7' |

or \( V_{-3.14510} \), \( VI + 1.57255 \), and \( III - 1.57255 \).

The Doctor likewise shews, that a system, (previously proposed by M. Henfling,) wherein the mean tone is to the major limma as \( 8 : 5 \), or the octave is divided into 50 equal parts, approaches very near to his favourite system of equal harmony, stating its temperaments (p. 157) at

| -41 | +25 | -16 |
| 148' | 148' | 148' |

which are equivalent to \( V_{-3.04975} \), \( VI + 1.85937 \), and \( III - 1.19008 \).

All these various systems treated of by Dr Smith, having their temperaments expressed in decimal parts of the schisma \( \xi \), will enable the reader to compare them readily, and calculate their beats by the 5th method, in p. 570 of our third volume. (q)

EQUAL Temperament, is applied to a system of intervals, wherein each concord, throughout the scale, is alike tempered, and wherein there are twelve semitones, precisely equal; and thence it is called the Isometric System; each of which semitones are \( = 51 \xi + f \), \( \xi + \frac{1}{10} \), and their ratio the 12th root of \( \frac{1}{3} \), which therefore is sure or incommensurate. But Mr Farey has shewn, that a commensurate system, seven of whose half-tones are of the value \( 51 \xi + f \), \( \xi + \frac{1}{10} \), and five of them of the value \( 51 \xi + f \), \( \xi + \frac{1}{10} \); also, eleven of whose fifths are of the value \( 537 \xi + f \), \( \xi + \frac{1}{10} \), and one of the value \( 357 \xi + f \), \( \xi + \frac{1}{10} \), differing at the most
only in each case, or less than the $\frac{1}{4}$th part of a major com- may yet this temperament, so perfectly and, to a practical discovery of the error, in the use of it, may be tuned throughout, by perfect intervals, that is, true fifths, fourths, and thirds, properly combined. See Farey's Temperaments. (q)

ERASMUS, OF DESIDERIUS. * one of the most celebrated scholars of his age, was born at Rotterdam on the 28th of October 1467; and though doomed to struggle, from his birth, with all the disadvantages of poverty and obscurity, yet, by the sole aid of his talents and application, he acquired the favor and protection of the most distinguished personages of that eventful period in which he lived. He was the natural son of Gerard, a native of Tergou, by Margaret, the daughter of a physician in Sevenbergen, whom his father intended to marry; but, being deceived by a report of her death, he became disgusted with the world, and took orders in the church. When little more than four years of age, Erasmus was so remarkable for his musical voice, that he acted as chorister in the cathedral of Utrecht; and when he had attained his ninth year, he was sent to a school at Daventer, where he made great progress in learning, and possessed so excellent a memory, that he was able to repeat the greater part of Terence and Horace. At thirteen years of age, he was deprived of both his parents; and his guardians, with a view to embezze his little patrimony, forced him into a monastery. His constitution, which was naturally delicate, rendering him unable to bear the watchings and other austerities of the monastic life, and his whole sentiments and temper being equally averse from the habits of the profession, he accepted, in his 23rd year, an invitation from Henry a Borgis, Bishop of Cambrai, in whose family he admits that he wanted for nothing, but from whose patronage he derived very little assistance. In 1496, he went to study at Paris, where he supported himself by instructing a few pupils in private, and where the literary exertions, to which he was compelled by his necessities, greatly contributed to his future eminence. By the friendship of some of his pupils, who were the sons of Englishmen, and particularly of William Lord Mountjoy, who afterwards allowed him an annual pension of a hundred crowns, he visited England in 1497, and formed an acquaintance with the most eminent literary characters of that country. During the succeeding ten years, seems to have frequently changed his place of residence, and to have visited various parts of France, England, and the Low Countries. He was most stationary, however, in Paris, where he employed himself in the study of the Greek language, and in the composition of his early publications. He complains, in his epistles, that want of money prevented him, about this time, from finishing many of his treatises, and compelled him to spend much of his time in reading lectures to young students. He received, however, frequent donations from his friends and patrons, particularly from Anne Bersal, Marchioness of Ure, whom he often addressed in letters of the most complimentary style, and to whom he made known his pecuniary wants with very little delicacy. About the beginning of the year 1507, he went to Italy, in order to take a doctor's degree, which, he observes, "makes one neither better nor wiser, but must be done, if a man would be esteemed by the world."

Having resided about a year in Florence, he proceeded to Venice, where he published a third edition of his Adages; and, after spending a short time at Padua, he arrived in Rome in 1509. At this time, he was acting as tutor, to Alexander, Archbishop of St. Andrews, natural son of James IV., of whom he draws a very high character, and who was afterwards slain, with his father, at the battle of Flodden Field. At Rome, he at first experienced the most flattering attentions, and received several advantages offered to induce him to settle in that capital; but at length he seems to have questioned the sincerity of his Italian friends, and, in his "Praise of Folly," which he wrote soon after, expressly complains of the neglect with which he was treated by the papal court. He gladly accepted, therefore, the invitations of Henry VIII., and of his former pupil, Lord Mountjoy, to return to England, where he continued a considerable time in great favour with the King, with Wolsey, with Warwick, Archbishop of Canterbury, with Sir Thomas More, and many other nobles and prelates of distinction. Invited to Cambridge by Fisher, Bishop of Rochester, he was promoted successively to the divinity and to the Greek professorship; and continued to teach publicly in that university for the space of four years. Though received many valuable donations, and derived several small annual pensions from the liberality of his patrons, or from the livings with which he was presented, he was always in poverty, and always importuning his friends for pecuniary assistance. Either from want of economy, or from the infirm state of his health, which required many indulgences, or from his satirical disposition, which alienated the affections of his admirers, he found himself unable to subsist in England; and, in 1514, he removed to Germany, where he was appointed nominal counsellor to Charles, Archduke of Austria, with an annual stipend of 200 florins. From the period of his publishing the "Praise of Folly," he was no longer considered as a true son of the church; and his incessant invectives against the monastic orders, drew upon him the bitterest persecutions from that quarter. In order to shelter himself from their slanders and machinations, he petitioned and procured from Pope Leo X. a dispensation, in due form, from the vow which he had reluctantly made in his youth among the regular canons. In 1516, he published, and dedicated to Leo, his edition of the New Testament in Greek and Latin, with notes, a work which had long occupied his chief attention, and which, while it drew upon him the censures of ignorant and envious critics, was highly valued by all who were capable of appreciating its merits. About the same time he produced, and inscribed to Archbishop Warkam, an edition of the works of Jerome, to whom he professed, in rather exaggerated terms, to hold in the greatest estimation, as an author and

---

* His original name was Gerard, signifying "amiable," which, according to the custom of the times, he rendered into the Latin epithet Desiderius, and the Greek Erasmus, or rather, as he afterwards wished to have expressed it, Erasmus.
theologian. He received the most pressing invitations from Francis I. to settle in his dominions; but dreading the envy of the French litterati, and the persecutions of the Doctors of the Sorbonne, and being unwilling to forsake possessions for promises, he retained his preferments under the Emperor. In 1517, he revisited England, and was very courteously received by the king and by Cardinal Wolsey; but, though he declined their offers to provide for him in that kingdom, he mentioned to one of his friends, that his English revenues constituted his chief support. In the same year he published a work entitled Querela Pacis, in which, with much soundness of reasoning, power of eloquence, and freedom of sentiment, he expostulates with the sovereigns of the world upon the atrocities of war, and pronounces all hostilities which are not strictly defensive, to be unlawful and unchristian. A benevolent project for a congress of princes at Cambrai, who should enter into mutual engagements for the preservation of peace, having been unhappily thwarted by the arts of interested persons, Erasmus wrote his "Complaint of Peace," in the request of John Sylvius, Chancellor of England, who had been a zealous promoter of the plan. (The work was dedicated to Philip of Burgundy, Archbishops of Utrecht, who expressed his approbation, by offering the author a benefice, and presenting him with a valuable sapphire ring, which he requested him to wear for his sake.) During the six succeeding years, he resided chiefly at Louvain; and, by the commencement of the Reformation under Luther, was involved in new difficulties and disputes. Hitherto, he had often experienced the enmity of the scholastic divines, and of the monastic orders, of whose absurdities and immoralities he had so openly assailed in his writings; but he found no difficulty in carrying their attacks, and preserving the favour of the most zealous Catholic princes and prelates. But, as the struggles between the Romanists and the Reformers became more serious, it required his utmost exertion of ingenuity and caution to preserve at once consistency of sentiment, and security from persecution. Both in conversation, and from the press, he had been accustomed to inveigh against many of those errors in doctrine, and superstitions in worship, which disgraced the church of Rome. Some of these he ably confuted by the utmost solidity of argument and force of eloquence; while he directed against others those weapons of ridicule and sarcasm, which he was able to wield with such irresistible effect. Nor did he spare even the character of the ecclesiastics; but, with the greatest ability and most exquisite brilliancy, exposed to the world their spiritual domination, their impious frauds, their ambition, avarice, and luxurious excesses. Scarcely did one of those opinions and practices, which Luther afterwards attempted to reform, escape the animadversions of his pen; and, as his writings were read with universal admiration, they contributed, in no small degree, to the progress of the Reformation: "Luther," it was said, "hatched the egg, which Erasmus had laid." Nor was he merely the forerunner of the great reformer; but, for some time after Luther had commenced his career, he acted as his admirer and auxiliary; applauded his conduct, and expressed hopes of his success; recommended moderation in his measures, but encouraged him to proceed; vindicated his character to the dignitaries of the church, condemned the spirit of his adversaries, and always insisted that his books should be answered by reasoning, instead of being suppressed by authority. In several of his publications, he openly concurred with him in denouncing the obscure and unedifying systems of the school divines, and calling the attention of mankind to the study of the Sacred Scriptures, as the only standard of religious truth. In his celebrated "Colloquies," particularly, which he published in 1522, he directs his severest strokes against the monks and their superstitions; and so manifest was his reforming tendency, that the Faculty of Theology at Paris, and afterwards a provincial council at Cologne, denounced it as "a wicked book, the perusal of which should be forbidden to all, especially to the young, and which ought, if possible, to be entirely suppressed." But, though he entertained so great a similarity of sentiment with the reformers, he was prevented, by a variety of circumstances, from decidedly espousing their cause. His extreme love of peace rendered him averse from those measures of direct opposition to the church, which had become necessary, and flattered him with the delusive hope of a gradual reformation by gentler methods. His excessive deference for persons of high station, his intimate acquaintance with the more learned ecclesiastics, and his love of the literary reputation which he had and feared among them, kept him from embracing a party, to which his patrons and friends were personally adverse. His dread of losing the pensions and other emoluments, which he derived from the Catholic princes and prelates, may be supposed to have had a considerable influence upon his conduct. His natural timidity of mind, particularly disqualified him for encountering persecution; and, by his own confession, would have induced him to consult his personal safety, however much he had approved the sentiments and measures of the reformers. "It is true," he writes to his friend Richard Pace, dean of St Paul's, "Luther hath given us many a wholesome doctrine, and many a good counsel; and I wish he had not defeated the effect of them by his intolerable faults. But, had he written any thing in the most unexceptionable manner, I had no inclination to die for the sake of truth. Every man hath not the courage requisite to make a martyr; and I am afraid, were I put to the trial, I should imitate St Peter." There is no reason, indeed, to suppose, that those motives, powerful as must have been their influence upon such a feeble temper as he possessed, engaged him either to act or write in direct opposition to his conscience; but they may have biased his judgment, while he was unconscious of their operation, and may serve to palliate, while they cannot excuse, the unworthy concealment and concession of his opinions, by which he endeavoured to ensure his tranquillity. While he embraced every opportunity, in his epistles, to disclaim all connection with Luther, he was equally anxious to evade the repeated attempts which were made to engage him in a controversy with the reformer; and, on one occasion, when exhortcd by Mountjoy, to repel the accusations of heresy with which he was assailed, by taking up his pen in defence of the church, he frankly replied, "Nothing is more easy than to call Luther a blockhead; nothing less easy than to prove him one; at least so it seems to me." At length, partly irritated by the reproaches of the more zealous reformers, and partly apprehensive of incurring the displeasure of the court of Rome, he proceeded first to repress his own zeal against the abuses in the church; then to assume the character of a mediator between the contending parties; then to censure the impetuosity of Luther's proceedings; and finally, to enter the lists as his antagonist.

Upon a rumour probably of his intention to attack
the reformers from the press, Luther addressed him in a letter, full of spirit, yet expressed with much aposto-

lesque dignity, in which he reminds him of his weakness, and exhorts him to continue to be a spectator rather than an

actor in the contest: “We saw the Lord had not conferred on you the deernament and resolution to join us, and openly expose those monsters; therefore dared not exact from you what greatly surpasseth your strength and capacity. We have even borne with your weak-

ness, and honoured that portion of the gift of God which is in you.” “On the other hand, my dear Erasmus, if you duly reflect on your own imbecility, you will ab-

stain from these sharp and spiteful figures of rhetoric; and if you cannot or will not defend our sentiments, you will let them alone, and treat of subjects which suit you better.” In 1525, however, Erasmus commenced open hostilities, by publishing his Diatrib of libero Arbitrio, in which he merely opposes the opinions of Luther on Predestination; a subject, which he seems to have purposely selected, as it furnished the appearance of dissenting from the reformer, while it was alto-

gether unrelated to his more obnoxious tenets; and in the discussion of which, he was in fact led to controvert the sentiments of St Augustine and of Tho-

mas Aquinas, as much as those of the German divine. In a letter to Melanthon, he makes an apology for this publica-

tion, alleging in his defence, that the calumnies of the ecclesiastics, who made him pass for a Lutheran, and the importunity of princes, whose authority he could not disregard, had constrained him to write; and intimating at the same time, as a farther proof of his general good will, that he had employed all his influ-

ence to prevent the exercise of cruelty towards the re-

formers. Luther replied in a treatise, entitled De servo Arbitrio, in which he appears greatly superior to his op-

ponent in the knowledge of the subject, and the man-

agement of the argument; but treats him throughout with very little courtesy, which, indeed, he had not much title to expect; and assails him with a mingled volley of compliment and scorn, of commendation and

invective. Erasmus renewed the controversy, by pub-

lishing his Hyperaspistias, and the dispute was carried on with augmented and unjustifiable acrimony on both sides. After the year 1525, Erasmus resided several

years at Basle, a place to which he was much attached, and which his enemies used to call his city of refuge.

He was made rector of the university, and being sur-
rounded by friends in whom he could confide, he found himself more secure from injury among the reformed divines of that city, than among the Romish monks and ecclesiastics. But when the Protestants gained the ascen-
dency in the revolution which took place there in 1529, he became apprehensive of being suspected as their coadjutor should he continue among them, and removed to Friburg. In the course of the year preced-
ing his removal, he published two treatises in the form of dialogue; one of which, the most learned of all his writings, discusses “the right pronunciation of the Greek and Latin languages;” and in the other, entitled Cicero-
nianus, he rallies, with great ingenuity and sprightli-

ness, the servile followers of Cicero, who scrupled to

employ any word or phrase which was not to be found in

his works. This latter production drew upon him much odium from many of his learned contemporaries, whose sentiments he controverted, or whose merits he had failed to praise, according to their expectations; and particularly from Julius Scaliger, who published two orations against him so full of bitterness and secur-

ity, that his own friends expressed their dissatisfac-

tion, and prevailed upon him, after the death of Eras-

mus, to do justice to his memory. As Erasmus advan-
ced in life, he lost much of that openness and candour which had distinguished his early years; and so anxio-

us did he become to disclaim the cause of the reform-

ers, that, besides dissembling, he proceeded to con-

trict his most avowed sentiments. He had always professed his abhorrence of every thing like cruelty in the

measures which were adopted for suppressing the

principles of the Reformation; but, when some of the

Protestants began to produce passages from his writ-
ings, which seemed to favour their cause, and particu-

larly to deny the lawfulness of putting heretics to death, he was so fearful of being suspected by the persecuting

princes of his day of condemning their barbarous do-
ings, that he published a letter “against some who falsely call themselves Evangelists,” in which he main-
tains, with unusual acrimony, that there were certain heretics, who might lawfully be put to death, as guilty of blasphemy and sedition. These unworthy conces-
sions on his part were duly appreciated by the court of Rome; and, as he was now the declared defender of the

church, it was resolved to prepare him for receiving a seat in the College of Cardinals; but these rewards came too late, and his increasing infirmities obliged him to
decline the preferments which were offered to him in that view. In 1536, he went to Basle, in order to superin-
tend the printing of his Ecclesiastes, and in the hope of recovering his lost health; but his strength continued

rapidly to decline, and he died of a dysentery on the 12th day of July 1536, in the 69th year of his age. He was

buried with great funeral pomp in the cathedral church of Basle, where his tomb still remains, and where his cabinet, containing his ring, seal, pencil, knife, sword, portrait, and the New Testament written by his own

hand, is exhibited to strangers, as one of the greatest curiosities in the city. His memory is equally honour-
ed at Rotterdam, by an inscription upon the house in which he was born, and upon the college which bears his name; and by a bronze statue in the great square.

By his will, he left handsome legacies to several of his friends, and directed the remainder of his property to be applied to charitable purposes; by which it appears that he was neither so straitened in his circumstances, nor so defective in economy, as he was accustomed to represent himself. He is said to have left more than 7000 ducats. Erasmus was rather of low stature, but

well formed, of a fair complexion, with grey eyes, a cheerful countenance, a low voice, and agreeable elocu-

tion. His bodily constitution was very firm; and, among other peculiarities, he was not able to endure even the smell of fish, which made it necessary for him to procure a dispensation for using other food in Lent, and which gave him occasion to say of himself, that how-
ever friendly to the church in principle, he had a most Lutheran stomach. He was always neat in his appa-
rel, facetsions in his disposition, and fond of a witty sto-

ry though directed against himself. He used to dine late, that he might have a long morning for study; but after dinner, he conversed cheerfully with his friends on any subject, and delivered his opinions both on men and things with the greatest freedom. In his intellec-
tual character, he was distinguished by a strong mem-

ory, extensive reading, a penetrating genius, and a

lively imagination. He composed with great facility, but disliked the task of revising his writings. His prose

style in Latin, (the language to which he chiefly devo-

ted his attention,) though not always classically pure, is uniformly unaffected, clear, and copious; but his
verses in that language, though sufficiently correct in point of prosody, and distinguished by good sense, discover little elegance of taste, or poetical talent. He was constant and faithful to his friends, but too apt to trouble them with complaints against his adversaries; and, though generous and charitable to those who were poorer than himself, he was not very delicate in soliciting and accepting pecuniary donations from his patrons. With all the allowances which can be fairly made for his prejudices of education, his love of peace, and his reluctance to offend his best friends, he cannot be acquitted of timidity, lukewarmness, dissimulation, and a partial desertion of principle in the business of the Reformation; but he spent a long life in opposing ignorance and superstition, and promoting the interests of sound literature and true piety; and, with all his failings, he must unquestionably be regarded as one of the principal ornaments of the age in which he lived. His works, which were very voluminous, consist of translations from the Greek; grammatical and philological dissertations; various treatises on moral and religious topics; a version of the New Testament; parables and commentaries on several parts of sacred scripture; apologies, epistles, declarations, orations, poems, adages, epigrams, editions of celebrated authors, &c. His parables were the most favourably received of his theological productions; and his colloquies, and praise of folly, have been the most frequently printed of all his writings. The best and most elegant edition of his works is that published in Holland by Le Clerc, in eleven volumes folio, 1703. See Jortin’s Life of Erasmus; Bayle’s Dictionary; General Biographical Dictionary; Robertson’s History of Charles V. vol. ii. p. 156; Le Clerc’s Bibl. Univ. tom. viii. p. 213; Müller’s Church Hist. vol. iv. App. p. xvi. and pp. 845, 943, 1060. (q)

ERECHTHEUS. See Botany, p. 258.

ERFURT, Erfurt, or Erfurt, formerly Erpē, or Erpīa, is an ancient town of Germany, pleasantly situated on the river Gera, which flows through the town in numerous branches. Although the town is in general ill built, yet it possesses several public buildings of importance. The cathedral, which was built in 792 contains a huge bell, which weighs 30,250 pounds. In the cedevant convent of the Bernardins, is shewn the tomb of the famous bigamist, the Count of Gleichen, who is said to have been interred there beside his two wives. The university of Erfurt was established in 1592, and half of the chairs were filled by Catholics, and the other half by Protestants. In 1754, the Academy of Sciences was founded, which was subsequently enlarged by the addition of a botanical garden, an anatomical theatre, an observatory, a riding school, and a society of natural history. The principal public libraries are those of the University, of the Academy of Physics, of the Scottish Benedictines, and of the Lutheran ministry. The library of the Scottish Benedictines possesses a cabinet of physical and mathematical instruments; and that of the Lutheran ministry contained some ancient MSS. of the Hebrew Bible. The house for the orphans of Lutherans was formerly the monastery of the Augustins, and contains a cabinet of natural history. Erfurt formerly contained eight monasteries, four Catholic churches, and nine Lutheran churches. The town is defended by the fortress of Petersberg, which was generally considered as a place of strength till the year 1806, when the French entered it without resistance. The country around Erfurt is fertile in corn and vines, and abounds in bastard saffron and anise, which the inhabitants cultivate with great care. Almost every house in the town has a garden, hence the number of gardens amounts to about 1200.

A variety of manufactures are carried on at Erfurt, but the principal ones are those of woollen stuffs, leather, and ribbons, the last of which gives employment to 1500 individuals. Population 17,000. Its position, according to trigonometrical observations, is east longitude 11° 2' 26", and north latitude 50° 58' 45". For an account of the Academy of Erfurt, see our article Academy. See also Erfurt und das Erfurtische Gebiet, Vom Prof. Dominicus, Gotha 1798, vol. ii.; and Erfurt mit seinen Merkwürdigkeiten und Alterthümern, Vom D. Arnold, Gotha 1802, 8vo. (w)

ERIVAN, Erivan, or Irivan, a town of Armenia, in the Persian empire, and capital of a province of the same name. The province is bounded by the Russian, hills on the north and west, by the Araxes on the south, and by the districts of Karadag and Karadagh on the east. The town is situated on the banks of the Zengi, in a plain surrounded by mountains. It is defended by a fortress of an elliptical form, and upwards of 6000 yards in circumference. The north-west side of the town stands upon a precipice, about 600 feet high, and impeding over a river; but it is commanded by the fort, which is surrounded with two strong walls flanked with towers. The town is large, dirty, and ill built. The churches, which resemble catacombs, are small, and half buried in the ground. There are 28 poorly endowed convents in the town and neighbourhood for both sexes.

Erivan does not at present contain a tenth part of its former population, and it has been reduced by repeated sieges to a ruinous condition. In the year 1808, the Russians under General Godovitch blockaded the town for nearly six months, and at last attempted in vain to carry it by storm. They were repulsed with great slaughter, and nearly half of the army was lost during its retreat to Tiflis. The Turks and Persians, however, have repeatedly taken the town; and it has remained in the possession of the latter since the peace of Nadir Shah, in 1748.

About two days journey to the north-east of Erivan, is the beautiful lake which the Persians call Deria Shireen, or Goucheh. It is about five furlongs in circuit, and abounds in trout, and other delicious fish. The Armenian sanctuary of the three churches, which Sir John Chardin has particularly described, is about nine miles from Erivan. At a short distance to the south of the town is the famous mountain of Ararat, where the ark rested after the deluge. According to Major Sutherland, it forms an angle of an immense range of mountains, and has two summits, on the highest of which the natives believe that part of the ark still re-

ERZERUM, ERZAEUM, OR ARZERUM, the name of one of the most considerable of the pachalics of Armenia, and of the principal place of the pachalic. It is said to be divided into 12 districts or sunjets, governed by a pasha of three tails, who resides at Erzerum, the capital. This city, known by the name of Erze, is one of the most populous and flourishing cities in the kingdom, and is situated about three or four miles from one of the streams which run into the Euphrates. The town is ill built, the streets are very dirty, and the houses are for the most part low, and built of wood. The bazaars are large and well supplied with provisions; but fruit is very scarce, as it is all brought by the Georgians from the province of Aksha, which is three or four days journey distant. In 1810 there were nearly 40 mosques, four of which were deemed handsome, a Greek church, a large Armenian chapel, and three celebrated monasteries at some distance from the city.

The town is surrounded with walls, and on the south it is protected by a citadel mounting 20 pieces of cannon of various calibres. The eastern face it has regular embrasures; but from its want of solidity, it is equally defenceless with the rest of the castle. On the north side of the town is a very high mountain, covered with eternal snow. The plain in front is about 20 miles in circumference, and is adorned with more than 60 villages. In the year 1807, when the French legation under General Gardanne passed through this place, there was on the ramparts a house in ruins, which was used for leprous persons. The plague then raged in the town, carrying off from 20 to 25 persons daily. The principal articles of manufacture in Erzerum are copper, the ore of which is brought from a place about three days journey from the town, and the skin of a species of mart. Erzerum is the staple of the merchandise of India, consisting of silk, cotton, painted linens, spices, rhubarb, madder, and zedoary.

The climate of Erzerum is intensely cold in winter, but the air is salubrious, the water good, and the natives strong and healthy. The winter commences in the middle of August, when the snow begins to fall. It continues on the ground from October till March, when it melts, and causes all the rivers in the country to overflow their banks. According to Mr Macdonald Kinneir, the population of the city was about 100,000, of whom 15,000 were Armenians, and the rest Turks, with the exception of 200 or 300 Greeks. The author of the "Journal," who accompanied the French legation in 1807 and 1808, makes the population 150,000, and says that 500 of these were Armenian catholics.

Erzerum is five ordinary days journey from the Black Sea, thirteen from Diarbeker, and nine from Bayazid. It is situated in East Long. 40° 57', and North Lat. 39° 57'. See Journal d'un Voyage dans la Turquie D'Asie, et la Perse, fait en 1807 et 1808, p. 21. Paris 1809; and Macdonald Kinneir's Geographical Memoir of the Persian Empire, p. 321, 322. Lond. 1813. (w)

ESCUAPIUS. See Esculapius.

ESCURIAL, the name of a village in Spain, about seven leagues from Madrid, and celebrated for the magnificent palace of the Escurial, or St Lorenzo, which has been deemed by the Spaniards the eighth wonder of the world. This splendid structure was begun in 1557, by Philip II. in commemoration of the battle of St Quentin, which he gained on the day of the Spanish saint St Lorenzo, from which it received its name. The first architect was John Baptiste Manegro of Toledo, and upon his death, in 1567, the work was continued by Bustamante, one of his pupils, who died in 1597.

The building, which consists of grey stone, from the neighbouring quarries, is arranged in the form of a gridiron, in allusion to the martyrdom of St Lorenzo. The dome of the church is surrounded with eight symmetrical towers, which give a fine effect to the whole edifice.

The Escurial is a long parallelogram with four fronts. The principal or north front is 637 feet broad, and 51 high up to the cornice. It is flanked at each angle with a tower 180 feet high. It has three entrances, and 200 windows. The lower part of the central gate is adorned with eight Doric columns, and the upper part with four Ionic columns. The front on the opposite side towards the east, is of equal extent, and is approached by a large square raised on arches like a terrace, and surrounded with a lofty balustrade. The west and south fronts are of the same dimensions; the latter having five rows of windows, and the former almost none.

This vast building affords accommodation to a community of monks, as well as to the sovereigns of Spain.

The apartments occupied by the monks contain various objects deserving of notice. The chapter room and the prior's apartment, contain many admirable pictures. The old church is 129 feet long, and 33 feet broad. The refectory is 163 feet long, and 33 broad. Among other paintings, is a Lord's Supper by Titian, which is greatly admired. The ground cloister is a square formed by a double row of piazzas, one above the other, 93 feet long on each of the four sides, and 17 feet broad. The walls of the lower cloister are covered with paintings by the first artists. The staircase from the lower to the upper cloister is adorned with fine fresco paintings, one of which represents the foundation of the monastery, and the battle of St Quentin. The upper cloister itself is ornamented with the finest pictures.

The double cloister, which is built of granite, is 52 feet high, and has four grand fronts, one at each side opening on a spacious court of 88 arches, eleven in each row, supported by 96 columns, which are Doric below and Ionic above. The area of the cloister is divided into several compartments. A small octagonal temple about 52 feet high and 26 in diameter, and terminating in a dome, occupies the centre. Without it is built of granite, and of fine jasper marble; and its eight sides are alternately adorned with projecting columns, or with statues as large as life; all the ornamental sculpture being wrought in Genoa marble.

The libraries are peculiarly valuable and interesting. In one of the libraries is a collection of books in Latin, Hebrew, and Arabic characters, with an assemblage of 4300 MSS. of which 367 are Greek, 67 Hebrew, 1065 Arabic, and 1820 in Latin, Castilian, and other languages. In this number are included several Bibles, particularly the Greek Bible of the Emperor Cantacuzene. There is also in this library a collection of ancient and modern medals. A part of the other library, which is deposited in a private cabinet, contains many choice designs and ancient MSS. Among these is a copy of the Four Evangelists, 700 years old, embellished with miniatures, and also a Greek Liturgy, supposed to have been written by St Basil. The apartment in which these are contained is adorned with fluted Doric columns, and the roof and frieze are covered with allegorical paintings. On a table in the centre, is a small octagonal temple, which represents Charlemagne in the midst of his princes and palatines. The temple is of silver, and is embellished with 20 pounds of lapis lazuli, 48 ounces of gold, and 1448 ounces of silver, besides agates, diamonds, and other precious stones. The monks are extremely attentive in shewing all these curiosities to strangers.

The royal apartments are adorned with the finest paintings, which are displayed in two adjacent galleries. One of these is called the Gallery of the Infants, and the other, which is the principal one, is 70 feet long, on the walls of which are traced many of the military achievements of the Spaniards, from which it has received the name of the Battle Hall.

The Campana communicates with the main building by a double gallery, one above the other, 86 feet long, and adorned with Ionic columns. The church is ascended by a fine staircase, 136 feet broad, and 34 long, which leads to a piazza, forming the foreground of the church. This piazza opens on five arcades resting on pilasters, which support Doric semicolumns. Above these is raised a second body, adorned with six statues of the kings of Israel, 18 feet in length, and formed of white marble inlaid with black. This front is flanked by two towers, which are used as belfries. The inside of the church, which is Doric, is in the form of a Greek cross, with a lofty dome in the centre. It is 513 feet long, and 194 broad, and contains 48 altars, enriched by fine paintings. A fine marble statue of St Lorenzo is placed over the holy water pot, and is supposed to have been an antique discovered at Rome. The interior of the choir is exquisitely finished, and the fine paintings of Cambiaso cover the walls and ceilings. The pulpits of cedar and ebony, resting on four columns of bronze, is finely ornamented; and there are two rows of stalls, including 228 seats. The chancel, which is raised by 12 steps, is adorned with bronzes, and has fresco paintings on the roof. The chapel contains two mausoleums, one representing the statues of Charles V., his Empress Elizabeth, his daughter the Empress Mary, and his sister the Queen of France and Hungary. The other exhibits the statues of Philip II., and of his three queens, Anne, Mary, and Elizabeth, all of gilt bronze. Three doors, adorned with crystal and bronze, lead under an arch into the chancel, and conduct to three com-

ESC

are separated by 16 double Corinthian pilasters. In the intervals are arranged 24 urns or tombs, four being in each angle. There are other two beyond the entrance, resting on the claws of a bronze lion, and both of marble. Sovereigns, principally of the Austrian dynasty, occupy fourteen of these tombs, each sepulchre having an appropriate inscription. Only two of the princes of the French line are interred here. A large bronze lamp, surrounded with 24 chandeliers, hangs from the centre.

On the east and south of the palace are a series of gardens supported with walls, and laid out in terraces, which give the appearance of hanging gardens. The ground is very unequal, and the greater part of them are disposed in the form of an amphitheatre. Ingeniously constructed stairs form the communication between the gardens.

A beautiful road, about a quarter of a league in length, and planted on both sides with lofty elms and linden trees, leads to the village of the Escorial. A subterraneous corridor, arched with freestone, and called the Mina, leads also to the village. Another road leads to Fresneria, a country house situated a quarter of a league to the east of the palace, and in the centre of it is a piazza, supported by Doric columns. The road to Madrid is excellent, but is through a naked country, without fields or pastures. In going from Madrid, it first winds along the Manzanares, and leaving the Casa del Campo, it passes Pardo, and then three houses in succession, where relays of horses are provided. It then conducts to Valde Morillo, from whence the Escorial is first seen.

The beautiful gardens of the Escorial are intersected by woods and meadows, containing numerous streams and fountains, and small lakes abounding with fish. In the middle of one of these lakes is a covered pavilion, adorned with eight columns, and encircled with a little garden bordered by a balustrade.

The lofty mountains which separate the province of Old and New Castle, surround the Escorial. They are dreary, bare, and uncultivated. Spacious reservoirs have been constructed in these mountains for collecting the water, which is conveyed by an aqueduct to supply the fountains. The royal family, before the Spanish revolution, inhabited the Escorial from September to December, a season almost wholly employed in devotion. Since the invasion of Spain by the French, the internal decorations of the Escorial have been greatly injured, and the finest paintings have been carried to the Louvre. The position of the Escorial, according to trigonometrical observations, is West Longitude 4° 7' 50", and North Latitude 40° 33' 50". See Townsend’s Travels in Spain, vol. ii.; Laborde’s View of Spain, vol. v. p. 143—155; Link’s Journey through Portugal, p. 302; and Francisco de los Padres Description breve del Monasterio de S. Lorenzo en el real del Escorial. (7)

ESK. See Dumfries-shire, Forfarshire, and Mid Lothian.

ESN, or Assn, the Latopolis of the ancients, is an important town in Upper Egypt, situated to the west of the Nile, between Assoum and Cous. This place is remarkable for its public baths, and its commerce. The Mahometans have several mosques here, and the Copts a church, which is served by two priests. The Copts from the most distant provinces of the kingdom, repair hither as a place of pilgrimage. The surrounding country is rich and well cultivated, abounding in grain and fruit. In the chain of mountains which stretches to the east of the Nile, and almost opposite to Esneh, are quarries
of a soft stone, which becomes hard in the fire, and is used in the fabrication of kitchen utensils.

This town is famous for the celebrated temple of Latona, which was formerly built; and we have given a drawing in Plate CXLVII. and in our article Civil Architecture, vol. vii. p. 532, to which we refer the reader.

East Longitude 49° 15', and North Latitude 25°. See Savary’s Letters, &c. vol. iii. and Denon’s Travels in Egypt, vol. ii. iii. (f)

ESQUIRA. See Hudson’s Bay, and Labrador.

ESQUIRE, in the strict and legal acceptation of the term, is a name of dignity next above the common title of gentleman, and below that of knight. Its etymology is evident. The English word was derived immediately from the French esqyuir, or, as it was formerly written, esquire; and the French term is derived from the Latin secutif or secutinus; the root of all the terms being the Greek word συκεύω, a shield. The rank of esquire was at first officiary, but now it is merely honorary. In its original acceptation, as denoting an officiary dignity, it may be traced among the Greeks and Romans. Euripides mentions shield-bearers, συκευηοι, and συκευηοες, and armigeri and συκευηηενους; and armigeri and συκευηηενους are employed by Plautus. Butes is mentioned by Virgil as Dardanie Anheloe armiger. Even among the Britons, according to Tacitus, the office of esquire or armiger-bearer was known; for he informs us, that Cartimandua, queen of the Brigantes, married the esquire (armigerum) of her husband. The knights of ancient Gaul were attended in their wars by two butes, or ministers, who seem to have been the same whom Pusidonius (apud Athenaeum) represents as sitting with them at table, bearing their shields. Indeed, almost all the ancient nations of Europe, who signified themselves in arms, appear to have had this office. The Longobards denominated the person who held it Schilpor, i.e. shield-bearer; and the Germans, in the time of Charlemagne, called him Schildknapp: an appellation not uncommon among our Saxon ancestors before the word esquire was borrowed from the French.

Originally the office of an esquire was merely to carry the shield of the knight to whom he was attached; but afterwards, as we have shown in the article Chivalry, (to which we refer for what relates to esquire as connected with that institution,) his offices were more important and numerous. Among the French, the grand esquire was master of the horse. His business was to assist the sovereign in mounting or dismounting from his horse, and to give him his sword and belt. In the court of the eastern empire, there was an officer called κυκλοφόρος, who used to bear before the emperor the sacred standard, and his κυκλοφόρος, or shield, in a case.

It appears, from these instances, that the titles, armiger, esquire, &c. did not originally imply that the persons possessing them were entitled to bear coats of arms, but only that their office was to carry the arms of the knights, or of those persons of superior rank to whom they were attached; so that there is no connection between the strict etymology of the name, and the common acceptation in which it is generally used.

The name of esquire began to be honorary about the time of Richard I. there being an instance of a person being made esquire by patent, with arms by this king. It is, however, still a matter of difficulty and dispute, what constitutes the distinction, or who is a real esquire; for it is a vulgar error, that any estate, however large, can confer this rank upon its owner. The following are undoubtedly entitled legally to this rank and denomination, viz. esquires of the body; of those there are four to attend on his majesty’s person: the eldest sons of knights, and their eldest sons successively; all noblemen’s younger sons, and the eldest sons of such younger sons—the two latter species of esquires, Sir Henry Spleman entitles armigeri notabile. Fourthly, such to whom the king gives arms with this title: these are created either by letters patent, or by investiture, which used to consist in a collar of S. S. and silver spurs: the right of primogeniture in their lineal posterity is also accompanied with this honour. Fifthly, esquires by virtue of their offices, as justices of the peace, but only while he is in commission, unless he is otherwise qualified to bear the title; the officers of the king’s courts, and of his household. All the titular lords, who are such on account of office, or of high birth only, have not, by the common law, any title but that of esquire. In the commission appointing those who were to treat of an union between England and Scotland, a person holding the highest civil station, next to the royal family, is denominated "William Cooper, Esquire, our Keeper of our Great Seal of England." Foreign peers are only esquires in law. To the five sorts of esquires already named, may be added the esquires of Knights of the Bath, each of whom constitutes three at his installation. The sheriffs of counties retain the title during their lives. The heads of some ancient families are said to be esquires by prescription. Colonels, Sergeants at law, and Doctors in the three learned professions, are ranked above the dignity of esquire, and next to that of knighthood. See Selden’s Titles of Honour. Verres’s Restitution of Decayed Intelligence. Blackstone’s Commentaries. (w. s.)

ESSAYING. See MINT.

ESSENES. See FREE MASONRY, and MYSTERIES.

ESSEQUIBO. See Berbice, Demerara, and Guiana.

ESSEX is a maritime county on the east coast of England. It is bounded on the east by the German ocean; on the west by the rivers Lea and Stort, with a part of Hertfordshire; on the north by the river Stour and part of Cambridgeshire; and on the south by the river Thames. It is divided from the county of Suffolk, on the north, principally by the Stour; from Middlesex, on the west, by the river Lea; and from Kent, on the south, by the Thames. Measured from east to west, its extent is nearly 60 miles; from north to south about 50. Its outline about 120 miles; its area, as ascertained from the map lately published by the Board of Ordnance, is about 942,720 acres. It was formerly supposed to contain upwards of one million of acres. Even on the lower and more accurate calculation, it reckons among the largest counties in England. Its figure is irregularly quadrangular; its maritime side, in particular, being indented and uneven. On the eastern coast of England there are three counties, which together form a tame continued tract of vast extent, undistinguished by any considerable eminence or ridge: Of these Essex is the most southern; but though it is flat, it is in general sufficiently elevated to be dry and arable. Towards the north-west the country rises; the most level tracts are those of the southern and eastern hundreds. It has been already mentioned, that its maritime side is indented and uneven; it is in fact broken into a series of islets and peninsula, which are deeply cut in by the arms of the
sea, and exhibit evident marks of the force of that element. Along the coast, the greater part of which is protected by embankments, there are extensive and valuable salt marshes; and that part of the county which lies along the banks of the Thames, is also, for the most part, low and marshy. The effects of the violence of the sea is no where more conspicuous than in that part of the coast of Essex called Walton Ness. This promontory formerly extended much farther to the east than it does at present; the ruins of buildings having been discovered at a considerable distance, particularly in a shoal called West Rocks, nearly five miles from the shore, which is left dry at the period of greatest ebbs. On these rocks, an island called Orwell, is traditionally reported to have stood; and the spot where the ruins are found is still distinguished by the appellation of the Town. On the coast of Dengey Hundred also, which is now protected from the sea by embankments, that element, in time past, made great depredations. Off the coast there is a sand called Buxey Park, and old seamen still living have heard their grandfathers say, that, when they were boys; Buxey Park was covered with trees.

The divisions of this county are both natural and artificial. Its natural divisions are into continent and islands; the latter are numerous, but not extensive, lying partly on the German Ocean, and partly on the river Thames. Mersey island, situated at the confluence of the rivers Colne and Blackwater, and separated from the mainland by the small channel called the Pyefleet, is about five miles from east to west, and about two from north to south. It possesses many natural beauties, is well wooded, varied with hill and dale, containing excellent springs, and of a rich and fertile soil. Towards the south of the county are the islands of Rustley, Havengore, New England, Potten, Foulness, and Wallasea. These are contiguous to each other, and possess a rich soil. Canvey island is in the south-west of the county, situated nearly at the mouth of the Thames, and surrounded by branches of that river.

The artificial divisions of the county are hundreds, towns, parishes, and hamlets. There are fourteen hundreds, and five smaller divisions, called half hundreds, viz. Becontree, Chafford, Chelmsford, Claverley, Dengey, Dunmow, Freshwell, Harlow, Havering-atte-Bower, Hinckford, Lexden, Ongar, Rochford, Tendring, Thorstable, Attleford, Waltham, Winstree, and Witham. There are three borough towns, Colchester, Harwich, and Maldon, besides the town of Saffron Walden. It contains 454 entire parishes, and four parts of parishes. There are in it fourteen divisional meetings, or petty sessions; and 140 acting county magistrates. It returns eight members to parliament, viz. two for the county, and two for each of the borough towns. It is in the diocese of London, contains three archdeaconries, and fifteen deaneries; is in the home circuit, and pays twenty-four parts of the land-tax. Its quota to the regular militia is 900 men; to the local militia, 3535.

Essex enjoys, on the whole, a mild climate; for though it is exposed to piercing winds from the east, especially during the spring months, these winds are not nearly so cold, or prejudicial to vegetation or health, as the same winds in the more exposed county of Norfolk. Part of the eastern and southern limits, for ten or twelve miles from the sea and the Thames, are subject, during autumn, to thick and unpleasant fogs, which are often productive of agues. This disorder is not nearly so prevalent or so dangerous as it was formerly, before the marshes were so well drained, and the land so highly cultivated as it is at present. The quantity of rain which annually falls in this county is comparatively small, not averaging more than twenty or twenty-two inches.

There is great variety of soil in Essex, though, perhaps, there is little of what may properly be called clay. The district called the Rodings, which contains eight contiguous parishes, on the west side of the county, near the borders of Hertfordshire, contains a soil that comes, perhaps, as near to clay as any part of Essex, but which, in fact, is only a strong wet loam. This loam is very fertile, but is proverbial for the hardness of its roads, and the unequal manners of its inhabitants. In the eastern part of the county, the soil for the most part is of a strong good staple, intermixed, however, with light dry turnip land. Towards the middle and northern part, bordering on Suffolk, the soil varies considerably, some being light, with a species of marl below the surface, at the depth of a foot, or a foot and a half, while other parts are of a moist and rather strong soil. In the western part, which borders on the river Lea, almost every variety of soil is met with, from a wet heavy loam, upon brick earth, to a light, thin, tender soil, upon gravel. Mr Young, in his agricultural report of this county, divides it into eight districts, in respect to soil, viz. the Roding district, where the soil is so wet and strong, that only one crop is taken after fallow; this district, according to him; contains 156 square miles; secondly, the district of fertile loam, which stretches along the banks of the Thames, and the shore of the German Ocean, and contains 255 square miles; and the third, fourth, and fifth districts, which lie partly on the borders of Cambridgeshire, and partly to the north of Rochford, consist of strong land, and contain 292 square miles; the sixth district, which is a turnip loam, and stretches from a little to the south of Colchester, past that town, to the borders of Suffolk, contains 114 square miles; the seventh district is very small, it lies in the north western corner of the county, the subsoil of this is chalk; the last district, according to Mr Young; consists of miscellaneous loams, and occupies nearly the entire centre of the county, besides part of the western border of it; it contains 681 square miles. From this account of the soil of Essex, it will be seen that this county is on the whole fertile, possessing some very rich soil, while scarcely any part of it contains soil of a very poor or unimprovable nature.

Although there are no large rivers in Essex, yet it is well situated in respect of river navigation. The Thames forms its whole southern boundary; the Stour, which is navigable to Shoebury, is its northern limit; and on the west it has the two navigations of the Stort and the Lea. Besides these, the estuary of the Black-water penetrates 15 miles into the county, and afterwards is navigable to Chelmsford. Nearly the whole of the county, except those hundreds near the Lea and the Thames, which are emphatically styled the Hundreds of Essex, is well watered by the many brooks and rivers which run through its vale. The principal rivers, which, properly speaking, belong to this county, are the Colne, which rises near Clare in Suffolk, and after passing Colchester, empties itself into a creek of the Lea, between Mersey island and the main. The Black-water, which rises near Saffron Walden, and flowing by Coggeshall and Witham, falls into an arm of the sea at Maldon; the Chelmer, which, rising near the source of the Black-water, fertilizes and beautifies the middle of the county, and passing by Chelmsford, unites at Maldon with the former river; the Crouch, which, after
a short course on the south-eastern side, joins the Lea among the marshes of Burnham and Foulness Isle; and the Roding, which enters the Thames near Bark-}

ing.

The state of property in Essex is such as might be expected from its vicinity to the metropolis, and the enterprising spirit and wealth of its farmers; for though there are a few very extensive estates in the possession of the nobility, or some very wealthy private individuals, yet, perhaps, in no county is there a greater number of moderate sized farms, the property of mere farmers, while near the metropolis the land is divided into small portions, to accommodate the merchants of London, or for the purpose of nurseries and garden grounds, to supply the wants and luxuries of that city.

The management of estates is entrusted either to attorneys, or to farmers of skill and experience. With respect to tenures, free-hold are by far the most numerous, extensive and valuable; next to these are copyhold; lease-hold estates are the fewest and least valuable. There are many estates in mortmain, belonging to Guy's and Christ's Hospitals, and other corporate bodies. The houses of many of the landed proprietors are magnificent; of this description are Wansted House, the seat of Mr Wellesley Long: this is one of the largest houses in the kingdom. Audley-end, the seat of Lord Braybrooke, is not more remarkable for its magnificence, than for the taste with which the grounds around it are laid out. Besides these, may be noticed Gosfield, the seat of the Marquis of Buckingham; Thorndon, the seat of Lord Petre; and Mistley Hall, the seat of Mr Highy.

Essex, like every other county in the kingdom where agriculture is well understood, and carried on in such a manner as at once to enrich the farmers, and benefit the nation at large, is distinguished for the size of its farms; though it would appear from the account of Mr Young, that there are not so many large farms now as there were in 1767, when he found, in the district of the hundreds, some of above £1000, £1500, and even £2000 and upwards per annum. One of the largest farms in the county at present contains 1600 acres. The character of the Essex farmers, in general, is highly respectable, not merely on account of their intimate knowledge of their own profession, both in theory and practice, but also on account of their general acquaintance with the sciences and arts connected with agriculture. The rent given for land in this county is certainly not high, when the general goodness of the soil and climate, and its vicinity to the best market, are taken into consideration. In the year 1806, the average of the Roding district was about 16s. an acre; of the second district of West Gracey, 25s. ; of the third district, 17s. ; of the fourth, 16s. ; of the fifth, 17s. ; of the sixth, 21s. ; of the seventh, 15s. ; and of the eighth, 20s. At that time the total rent was estimated at £9 46s. 3d., or, on an average of the whole county, not more than 20s. an acre. Since that period, rents in Essex, as well as elsewhere, have risen considerably, but not to the level of other districts, nor so highly favoured in situation, soil, and climate. The average of the poor rates amounts to 9s. in the pound; the proportion for tithes, per acre, in 1803, was 4s. 9d. Leases, which formerly were almost universal, latterly have become by no means general; where they are granted, ridiculous or impracticable covenants, which might have been proper a hundred years ago, are too often retained.

Agriculture. Essex may emphatically be deemed an arable county, not merely because by far the largest portion of the ground is under the plough, but also because its soil is of the best quality, and its fields exhibit some of the best specimens of English arable husbandry. Only two kinds of ploughs have gained a firm and general footing in the county; the swing and wheel ploughs, both constructed on a better principle, and much lighter and easier of draught, than are commonly met with in England. They are worked commonly with two horses, but sometimes with three yoked abreast, without a driver. The other agricultural implements are equally simple and well constructed with the plough; none, however, require to be noticed as peculiar to Essex, except the concave roller, and the bean stubble rake. Thrashing mills of various kinds are not uncommon, and one horse cart have been lately introduced.

Essex has long been an inclosed county; the fences generally consist of various kinds of wood; but they are, in most parts, so high and thick, that they exclude the sun and air.

On all soils, except sound dry turnip soil, following is practised in Essex, and the fallows are uncommonly well and carefully wrought, being frequently ploughed eight times. It has already been mentioned, that the Roding district consists of strong wet soil; in this district a singular rotation is followed, viz. fallow, wheat, fallow, barley. In the other districts, the rotations, though various, present nothing peculiar, except what arises from the crops peculiar to Essex, which will afterwards be noticed. This county has long been famed for the excellent quality of its wheat, which, with that from Kent, always obtains the highest price in the London market. This grain is either sown on a fallow, or after beans or clover; in some parts it is drilled and horse-hoed. Dibbling is also practised, but not to any extent. Till very lately, scarcely any spring wheat was sown, but now it is gaining ground. The mean produce of the county is about 15 bushels per acre. The barley of Essex is also in great demand; it is sown Barley, either after a fallow on strong lands, or on dry land after turnips, seldom after beans, peas, or teaces. The average produce of this grain is between four and five quarters: it is seldom made into bread, even the poorest of the people refusing to eat it, except in times of the greatest scarcity. Oats are sown after fallow sometimes, but more frequently after beans, &c. Tartar, potatoe, Dutch, and black oats, are sown: in some parts of the county, the produce is very large: the average of the whole probably about five quarters. Though a large portion of the soil of Essex is suited to beans, they are not esteemed so highly, nor cultivated so well and extensively, as they ought to be: where grown, they are generally put in after wheat, sometimes but not always dibbled, more frequently drilled; in both cases hand-hoed, but horse hoing is neglected: the average crop is supposed to be 27 bushels per acre. Near the metropolis, great quantities of white pease are sown; but this crop is not very common in other parts of the county. There is not much turnip soil in Essex, but turnips, the culture of this root is well understood where it can be practised: they are generally grown after early peas; sometimes, but not usually, drilled, and fed off either with bullocks or sheep: the average price for feeding on the land with sheep is £3 per acre. They are found to succeed best near the coast, it is supposed, from the influence of the sea air. Swedish turnips are also grown to a considerable extent, and a few cabbages. Potatoes, which have long been cultivated to a great extent in the northern counties, have comparatively made little progress in the south of England; Essex, however, is an exception to this remark; here
they are very largely grown, London receiving its chief supply of this valuable root from Essex. Near Barking is one of the greatest potato planters in the kingdom, who seldom grows fewer than between 200 and 300 acres. Clover, which most probably was introduced into England from Flanders, and first into that part of England which lies opposite that country, has been so long cultivated in Essex, that it is said now not to produce such certain and full crops as formerly; the same complaint is made in Norfolk. Rape or cole is much cultivated in most parts for food; and about Hedingham, Manningtree, &c. for seed: in the rich district of Romford, there have immense crops of this plant, and manage it in a most admirable manner. Hops were formerly much more extensively cultivated than at present; they are chiefly now grown in the parishes of Hedingham, Mapledstead, Colne, Chelmsford, &c.; the sorts are the Kentish, Essex, Worcester, and sometimes the Farnham: they are usually gathered in September. It is remarked, that the Kentish hop-pickers pick nearly one half more than those in Essex; the reason is, that the former work by the piece or task-work. The hops in this county are not very highly esteemed, at least in point of strength they are inferior to the hops of Kent, but not so in flavour. In the neighbourhood of Hedingham, the crops are sometimes very heavy, upwards of 24 cwt. having been gathered from an acre; the average produce is about eight cwt. Hop ground has been sold in this neighbourhood at the rate of £192 per acre, which is equal to 30 years' purchase at £6 per acre.

Treble crop. Hitherto, the different crops that have been enumerated, are grown in other counties as well as in Essex; but the following productions are peculiar to Essex; they form a treble crop, consisting of coriander, teasel, and caraway. The seeds of these plants are sown together; the farmer generally takes a partner in this concern, who sows the land, keeps it clean, and cuts, threshes, and prepares for market the crops, while the farmer provides and ploughs the ground. The connection lasts three years: in the first the coriander is ripe, and generally produces from 10 to 14 cwt. per acre; in the second year the teasel is ready, which generally yields a load or six score staffs, of fifty heads each staff: the caraway also this year yields from three to six cwt. of seed. It is not, however, till the third year, that this last comes to perfection, at which period it will yield from 10 to 14 cwt. per acre, while the teasel declines, only those plants coming to a head which were not sufficiently forward the preceding year. The heads of the teasel are bought by the woolen manufacturers for the purpose of dressing their cloth, but they are not nearly so much used for this purpose as formerly. In some parts of Essex there are gardeners, farmers, who travel about and take grass land, for the purpose of breaking it up and sowing it with caraway seed: they enter into partnership with the farmers, on the same terms as have been already specified. Mustard is cultivated in some of the islands of Essex, and in the embanked marshes. Saffron is not cultivated now in Essex to such an extent as formerly; it is principally grown between Saffron Walden and Cambridge, in a circuit of about 10 miles. One of the best proofs of good husbandry in a district, is the general use and judicious management of turnips where the soil is suitable, and of tares where the soil is too heavy and wet for turnips. In Essex there is not much turnip soil, but tares are extensively and judiciously cultivated. On the lands of this county which have a chalk bottom, saffoin is grown; but the crops are not very heavy. This valuable plant has also been cultivated on a sandy bottom, with more success than might have been anticipated. Though Essex is decidedly an arable county, and stands very high among the English counties for the goodness of this species of husbandry, yet the extent and value of its marshes, as well as the grazing qualities of the district of Epping, give it celebrity as a grazing county also. The proportion of grass land to arable, is supposed to be as one to seven or eight. Near London, considerable quantities of hay are grown; it is managed much in the same manner as in Middlesex; the produce is often very great, as not unfrequently three loads of 1800 cwt. each load, is got, at two cuttings, from an acre. All the marshes possess very rich and valuable grazing land; but those on the banks of the Thames are greatly superior to those on the ocean or Blackwater: the rent varies from £3 to £10 per acre; the latter are principally taken by the London butchers. The marshes in Dengie Hundred are singular, from the circumstance that they rise in elevation as they approach the sea. The great rise in the price of corn has induced several of the proprietors latterly to let their marsh land to be ploughed. Between the Blackwater and the Crouch, there are salt marshes, which are very valuable. The dairies of Epping and its vicinity are famous for the richness of their cream and butter: the cows used are principally the Holderness, Leicester, and Derby, though other breeds are often mixed. In making Epping butter, the milk is suffered to stand 24 hours, when the cream is skimmed off, and the milk is drawn into other vessels, where it remains for about 20 hours, when the cream is again taken off: this is called doubling. It is afterwards put into deeper vessel, when all the remaining cream is separated from it: this is called trebling. The butter made from the two last skimmings is of inferior quality. There is one thing peculiar to the dairy-women, which is, that there must be a certain proportion of sour in the cream; otherwise they cannot ensure good butter. The butter made by the smaller farmer is either carried to Epping market, or sold to higgles; but the large farmers generally agree with some Clare-market butter-man for the whole produce of the dairy.

Essex has long been noted for its calves. Formerly it was supposed that more were bred and fattened here than in any other English county; but the practice is on the decline. Besides the calves that are bred in Essex, great numbers are brought from other parts of the kingdom, and fattened here, especially by the farmers in the Burnham and Southminster marshes. To promote their fattening, they are frequently given a small ball composed of the powder of fenugreek, wheat-meal, and a small quantity of powdered chalk, mixed up with mild ale. Essex is not famous for its live stock, though in some parts the Devon breed of cattle are grazed; when early lambs are in demand, the Dorset sheep are kept; besides these, there are in the county a mixture of Norfolk, Welsh, and Wiltshire. Considerable attention has been paid to the breed of hogs; there is one kind very valuable, called the Essex half black; the Berkshire is the favourite breed in the southern parts of the county. The Suffolk breed of horses are generally employed for agricultural purposes. Oxen are seldom wrought.

There are several decoys among the islands and marshes; the most considerable is in Mersey island: when any person approaches the decoy, he takes a piece of lighted turf in his hand, as the wild ducks, it...
is said, would otherwise smell the person, and immediately quit the pond.

Timber.

Essex is a well-wooded county; for, besides the timber in the hedge-rows, it is calculated that there are upwards of 50,000 acres of woods and woodlands, which, connected with the hedge-root timber, are reckoned worth nearly three millions. There are some very large trees in the county; a cedar at Faulkburh Hall is supposed to be the largest in the kingdom; its girth, at six inches from the ground, being 18 feet; at 10 feet from the ground, 14 feet; and its height to the first branch, nine feet. In the church-yard at Woodford, is a remarkable yew tree; the spread of the boughs forms a circumference of 180 feet; its girth, at four feet from the ground, is 14 feet. But the most remarkable tree in Essex is the Fairlop oak in Hainault Forest; the tradition of the country traces it half way up the Christian era. It has lately been much injured by fire, it having been customary, on the first Friday in July, to hold a fair under its branches: on one of these occasions, it accidentally took fire. Before this accident, its branches overspread an area nearly 300 feet in circumference.

Forests.

In the reign of James I. the forest of Essex, as it was called, extended almost over the whole county. The forests of Epping and Hainault still retain the name, and support a few deer; the extent of forest land is supposed to be about 10,000 acres. In the marsh districts, elder plantations are much attended to, and are found to be very profitable. There are no extensive orchards of apple or pear trees, but many cherry ones at Burnham, Southminster, &c. The wastelands, including the forests, are estimated at 15,000 acres.

Draining.

The agricultural improvements of the county are many and numerous; of these by far the most important and the best understood is under draining. From the moist nature of a great part of the soil, this improvement was much wanted, and it has, in general, been carried on, on the most scientific principles, and with great care and skill of execution. Almost all the known kinds of manure are employed in Essex, but chalk is not so commonly used as formerly. From the nature of the sea coast, as well as the south boundary of Essex, embankments are absolutely necessary; indeed, the whole shores of Essex are embanked, except at Purfleet, Southend, and Harwich: most of the embankments are old.

We have dwelt thus long and fully on the agriculture of Essex, because it is in general excellent, and because it is this which principally distinguishes the county. In no other respect is it of much note, and therefore our remaining account will not detain us long. As intermediate between its agriculture and manures, its fisheries shall be first considered.

There are very few ponds for fresh water fish in the county, though, in the vicinity of London, they would pay well; and it appears, that formerly there were several ponds of this description. In Foulness Island there are salt water stews for various sorts of sea fish. But oysters are the fish for which Essex is particularly celebrated. The spats or small oysters are brought chiefly from Portsmouth, and the neighbourhood of Chichester. The principal breeding rivers in Essex are the Crouch, the Blackwater, and Colne. Though the produce of this fishery has obtained the general name of Colchester oysters, yet they are of several kinds; the Purfleet is in most request. The creek in which this species is found, extends from the river Colne, to the Strode, at the entrance of Mersey Island. The creeks extending from the Thames round, and those from the Mersey round, are also famous for producing good oysters. The Wallfleets and Burnham oysters are the produce of the creeks and pits of the river Crouch. The dredging boats employed are from 14 to 30 or 40 tons; the netting out one of 20 tons, will require £150. There are from two to four men in each vessel, who are paid by shares, and the master has a share for the vessel. There has been an increase of boats, and of course of men, of more than one half, within the last 50 years; the number of vessels being now upwards of 200, and of men and boys above 500. The quantity of oysters taken in a season is supposed to be above 20,000 bushels. The principal market is London; they are also sent to Hamburgh, Bremen, Holland, France, and Flanders. Many vessels belonging to Essex are also employed in the cod, turbot, mackerel, herring and sprat fisheries.

Formerly Essex was rather noted for its woollen manufacture; but latterly it has much declined. Baize, however, is still made at Bocking, Baintre, and Colchester; at the latter place, before the war in 1794, the number of hands employed, including the neighbourhood, was about 20,000; but the war reduced the number to about 8000. In some of the villages, sackings and hop bags are manufactured. Near Woodford Bridge is an artificial slate manufactory; not far from Leyton, on the Lea, are mills for making sheet lead; and in the vicinity of the metropolis, are several large calico printing manufactories.

The state and expense of supporting the poor, unfortunately constitute a very important article in the statistics of every county of England. On this subject there has been no official and accurate information since the year 1803. At that period, in Essex there were 177 parishes, who maintained their poor in workhouses. The number was 2969; the expense was at the rate of £231, 13s. 4d. for each person. The number of persons relieved out of workhouses was 35,368, besides 6780 who were not parishioners; the expense was at the rate of £3, 16s. 9d. for each person. The number of persons relieved in and out of workhouses was 38,337, besides non-parishioners. The total expense was £183,552, or at the rate of £24: 15: 9 for each person. The number of parishioners relieved by the poor's rate was 17 in a hundred of the resident population. There were at that time 238 friendly societies, the number of persons belonging to them being six in a hundred of the resident population. The amount of the total money raised for the poor, was 19s. 1d. the head on the population.

Essex is a very uninteresting county to the mineralogist. It is nearly exempt from quarries, or any mass of rocks; and it possesses no mines of any kind. It has, however, already been noticed, that chalk is found on the borders of the county. The most extensive chalk quarries are at Purfleet. On the estate of Mr. Whitbread here, there is a bold cliff of chalk, covered by many feet of surface loam. It appears to have been wrought for many years; but certainly never with so much enterprise, nor in such an economical and effectual manner, as at present. Most of the chalk is shipped in vessels, which can come nearly up to the quarry. But though Essex is so uninteresting to the mere mineralogist, there are appearances in parts of it, which must be instructive to the geologist. At Harwich, the conversion of the clay ooze into a stone so hard that it is employed for building, may be distinctly traced. There are masses of it which are at one end ooze, and at the other stone. There is also, in the cliffs near Harwich, a stratum of concreted shells; and va-
rious teeth of large animals, among which are some of elephants, have also been laid bare by the falling of the cliff. Bones of elephants have also been discovered in other parts of Essex. The whole island of Foulness, and probably some other of the Essex islands, has evidently been formed, as on it there are layers of oyster and cockle shells. In the banks of the Thames at Dagenham, a very destructive breach was formed in 1707 by the violence of the wind and tide. While the works for repairing this breach were carrying on, a very extensive stratum of mooring, or cotton wood, was found. This stratum was 10 feet deep. Several stags horns were lying above the mooring.

Antiquities. Numerous antiquities have been discovered in Essex. The great Roman way, now called Stane-Street, led from Colchester through the middle of the county to Bishop Storford in Hertfordshire. Of the five Roman stations in this county, Camulodunum, the present Colchester, was unquestionably the principal one. Tessellated pavements have been discovered in several places; and the remains of a Roman villa near Ridgwell.

Before the dissolution of monasteries, Essex contained 47 religious houses. Of these, two were mitred abbeys, six common abbeys, 52 priories, three nunneries, three colleges, two preceptories of Templars, annuities of three hospitals. These, so much of the remains of Waltham Abbey still remain, as to prove that it must have been, when complete, one of the most curious and perfect specimens of the ornamented columns, semicircular arches, and other characteristics of the Norman style of architecture. In the parishes of Chadwell and Little Thurrock are several caverns formed in the chalk, which are supposed to have been the granaries of the ancient Britons.

The celebrated Bow Bridge crosses the Lea about two miles to the east of London; it was built in the time of Henry I. and is supposed to have taken its name from being the first bow or arched bridge erected in this county: in the time of Henry III. a singular toll was granted, by which every person carrying across it a dead Jew, was obliged to pay eight-pence.

There are several singular customs, of great antiquity, still existing in Essex: the most extraordinary is the well-known custom of the manor of little Dunmow, by which a gammon, or parget of bacon, is delivered to any married couple, who would take a prescribed oath; the substance of which is given in the Spectator. The earliest delivery of the bacon, on record, was in the 33d of Henry VI. The last persons who received it, established their right in 1751. A very singular custom prevails in the manor of Rochford; this is the holding of what is called the Lawless Court: it is held in the open air, on the midnight of the first Wednesday after Michaelmas day; all the business is transacted in whispers, and the minutes are made with coal instead of pen and ink. The steward opens the court in as low a voice as possible; those tenants who neglect to answer are heavily fined, and every absentee forfeits double his rent for every hour's absence: the time of assembling is from 12 till cock-crow. In Chingford parish, there is an estate held in a singular tenure from the rector; on every alienation, the owner, with his wife, man-servant, and maid-servant, comes to the parsonage, where he pays homage in the following manner: He blows three blasts with a horn; carries a hawk on his fens; and his servant has a greyhound, both for the rector; he receives a chicken for his hawk, a peck of oats for his horse, and a loaf of bread for his greyhound. They all dine, after which he blows three blasts with his horn, and they depart. The custom of the manor of Woodford is that called borough English, by which the younger son inherits.

Several men of considerable celebrity have been natives of Essex; among whom may be mentioned, Philamon Holland, called the translator general of his age; he was born at Cheimsford in 1551. Thomas Audley, Lord Chancellor of England, in the reign of Henry VIII. Samuel Purchas, who enlarged and republished Hakluyt's Collection of Voyages and Travels: it is well known under the title of "Purchas' Pilgrimage;" and Sir Thomas Bee, the first English ambassador to the East: the celebrated Alexandrian MS. of the Greek Testament was brought by him into this country. Nor must Edward Bright, a shop-keeper of Maldon, be forgotten; few men have reached a greater size and weight than he; at the age of 12 he weighed 144 pounds. The late time he was weighed, about a year before he died, his weight was 584 pounds; his body, round the chest, was five feet six inches; round the belly six feet 11 inches; he died at the age of 29.

The Trinobantes inhabited Essex at the time of the Roman invasion; they had two considerable fortified stations—one of which was at Colchester. It is said that one of their princes invited Caesar into Britain, in consequence of disputes among his tribe. When the Romans divided the country, Essex was included in that part called Flavia Caesariensia; the five principal stations of the conquerors were all seated on the road which formed the fifth Iter, from London to Venta Icenorum. During a certain period of the Saxon Heptarchy, Essex formed a separate kingdom, called East Sax; Erkenwin is supposed to have been the first king in 527. Essex is less noticed by ancient historians than any other of the kingdoms of the heptarchy. William the Conqueror deprived 90 land-owners, of this county, of their lands; and the Norman barons constructed numerous castles, and tyrannised over the inhabitants. In the civil wars between the houses of York and Lancaster, Essex suffered much from the interference of the De Veres; and also in Charles I. time, during the long siege of Colchester. Formerly there were 12 castles in this county, four of which were denominatcd royal castles: there are two remaining, Languard Fort and Tilbury Fort; in the neighbourhood of the latter, Queen Elizabeth reviewed the army, which she had assembled to oppose the Spanish armada.

The population of Essex, in the year 1700, was 189,200; in 1750, 167,800; and in 1801, 234,000. On an average of several years, it is found that there has been one baptism to 33 persons; one burial to 44 persons; and one marriage to 128 persons. In 1810, the baptisms of males were 3792; of females 3075; total 7467: the burials of males 2807; of females 2531: total 5338: the number of marriages 1892.

The following further details on this subject are taken from the population returns for 1811:

| Inhabitants | 42,829 |
| Families inhabiting them | 51,645 |
| Houses building | 235 |
| Houses uninhabited | 1,012 |
| Families employed in agriculture | 28,517 |
| Do. employed in trade, manufactures, &c. | 14,182 |
| Do. otherwise employed | 8,944 |
See Young's *Agriculture of Essex*; Moreau's *History of Essex*; Lysons's *Environments of London*, vol. iv.; * Beauties of England*, vol. v. (*w.s.*)

ESTELA, is a manufacturing town of Spain, in the province of Navarre. It is watered by the rivers Ega and Uredér, is defended by a castle situated in a plain, and contains several churches and convents. There is a university in its neighbourhood, which was founded in 1505. Coarse woollen goods are manufactured in the town, and it contains some distilleries of brandy.

Population 4,500 (j)

ESTHONIA. See Revel.

ESTRELLA SERRA DE, the Mons Herminius of the ancients, is the most extensive and highest range of mountains in Portugal. It is a branch of the high range that divides Old and New Castile, and stretches, like most of the other mountain ranges in the peninsula, from north-east to south-west. It rises from a mountain plain of a considerable height, and is covered with snow during more than four months of the year. Link has estimated its elevation at 5000 or 6000 feet above the level of the sea.

The southern or highest part of the range is called Serra Branca, or the wild mountains, from their steep and rocky character; and the northern, or lower part of the range, is called Serra Minho, or the gentle mountains. The whole of these mountains consist of granite. The highest summit is called Malhão de Serra, and is a large but gently arched plain, of so great an extent, that the spectator does not at all observe the rough rocky sides that surround the mountain every where but to the north-east. There are two lakes in these mountains. One called the Lagoa Ecsura, or dark lake, is of a fine round form, and is most romantically situated, being surrounded with high and wild rocks. It is deep and cold. The Lagoa Rotunda, which is the smallest, is completely round. It is surrounded with high rocks, and is remarkable for the transparency of its water. The principal lake is called Lagoa Longa, or Comprides. It occupies the middle of a valley of considerable length, its breadth is unequal, and, from its marshy banks, it is less beautiful than the other two.

Many large and small rivers take their rise in this range, particularly the Mondego, the Vouga, and the Ave.

ESTREMADURA, Extrema Dauria, is a province of Portugal, which is bounded by Beira on the north, by Lusitania and Leiria on the south, and by the sea on the west. It extends about 140 miles from north to south, and about 70 in breadth, and contains 5440 square miles. It is cut in the direction of east and west by the Tagus, which throws itself into the sea at Lisbon. This province forms a long and narrow strip of land, extending along the sea shore from the embouchure of the Mondego to below the town of Setúbal. On account of its proximity to the Atlantic, the climate is remarkably mild, and is very salubrious and pleasant to those who are accustomed to it. During the period between the end of July and the beginning of September, everything is parched. Not a blade of grass is to be seen, and the evergreens are shrivelled up. The heat continues incessantly, with a sky almost always serene.

The north wind prevails in summer; but its direction being changed by the mountains of Cintra, it becomes a north-west, and cools the air considerably. The greatest heat always accompanies the east wind; and in the summer of 1799, the heat was 10° F. of Fahrenheit, a heat of 96° F. is not uncommon. The soil round Lisbon consists of limestone and basalt. In some places, the limestone is very close and excellent for building. The basalt begins at the bank not far from the sea, and then proceeds through Quelus towards Belas; meanwhile a branch of the basalt mountains stretches beyond Lisbon by the Aqueduct, and unite with the above-mentioned chain towards Belas. Hence the basalt country extends as far as Caleça de Montañhez. It properly forms only one mass of basalt, which is occasionally covered with limestone.

The mildness of the climate is peculiarly favourable to agriculture, and the soil is productive or unproductive, according to the quantity of rain which falls. Wheat is commonly sown in the neighbourhood of Lisbon; barley is also sown; but rice is only grown for cattle, and oats are never seen. The fallows are ploughed in autumn, a second time in May, and then at seed time, when the autumnal rains have softened the earth. Light soils are dug, but those which are heavy are ploughed with oxen of extraordinary size, strength, and beauty. The harvest is in May. The corn is generally threshed, but sometimes trodden out by oxen and horses. Putrefied plants are the only manure which is employed. Rice is often in ear in February and March, and is commonly cut down for fodder before it is ripe. Spanish potatoes are occasionally grown; but this root is generally imported from England and Ireland.

The mountains of Cintra consist of granite, composed of clear white quartz, a reddish felspar, and black mica, against which bears a white or foliaceous limestone, or a proper stinkstone. The south side of these mountains is arid, naked, and parched up, and consists of bare heaped up rocks, affording a wild and dreary prospect. The north side of the range is to a certain height covered with country houses, and charming quintas, forming a shabby wood of the finest trees, such as oaks, pines, lemon trees, &c. From the top, there is a fine prospect of the well cultivated valley of Colano.

The principal fruits of Portuguese Estremadura are citrons, lemons, oranges, grenades, figs, dates, and almonds. Great quantities of Lisbon wine are made in the province. Salt forms one of the chief articles of its commerce. The principal towns of the province are Lisbon, Leiria, Abrantes, Pombal, Alcobaça, Síbiral, Thomar, Santarem, Alanquer, Torres Vedras, Cintra, and Cascaes. The province contains 8 jurisdictions, 400 parishes, and 350,760 inhabitants.

ESTREMADURA, is the name of the largest and most fertile, though the least populous and least cultivated of the provinces of Spain. It is bounded on the north and north-east by the kingdom of Leon; on the east by New Castile; on the south and south-east by the kingdom of Seville in Andalusia; and on the west by the Portuguese provinces of Estremadura, Beira, Entre-Torro-uo-Guiadana. It is about 50 leagues long from north to south, and 45 broad from east to west, and contains about 2000 square leagues.

This province is intersected by ranges of hills, the Mineral-mineralogy of which has not yet been carefully examined. A mine of copper, in a blue and green mixed stone, occurs in the Sierra de Guadalpe, to the south of the village of Logroso. There is a lead mine, which
has been worked on an eminence called Vadija, or valley of Las Minas, about 2 leagues from Logroñon, on the road to Zalamea. Another occurs about a league from Alcocer, in a plain intersected by banks of calcareous stone and slate. Blood stones are found near Nabal Villar. A vein of whitish and tasteless phosphoric stone, which, when pounded, takes fire, and gives a blue flame, crosses the road obliquely from north to south, on leaving the village of Logroñon at the foot of the Sierra de Guadalupe. A black earth, which shines when rubbed between the hands, is found upon a very steep mountain on the road between Alcocer and Nabal Villar. Labarde says, that it is a mine of refractory iron. A mine of iron on a sandy stone, containing very fine red ochre, is found between Alcocer and Oriellona. A blackish mineral, which Mr Bowles regards as an infusible iron, which strikes fire with steel, and contains a red emery, is found on the mountain of Lares, about a league from Alcocer. This mine was worked by the Moors, who erected a fortress on the mountain, which still remains. The mountain is composed of a brown freestone, mixed with quartz. Near Alcocer, there also occurs a smooth emery, with grains, containing a small quantity of gold. It was likewise worked by the Moors.

Silver is found in a whitish stone, with a white mica, on the mountain to the north of Logroñon. It also occurs upon an eminence called Chantee, towards Zalamea, two leagues from the eminence called Vadija. It is found with lead, in a granite rock cut against its natural direction. The vein also contains spar, quartz, white and yellow pyrites, and a black shining and crumbling pyritous matter. This mine has been worked, but was abandoned in consequence of being filled with water. Mr Link informs us, that before he arrived at Almaraz, he found along the hill to the northward of the Tagus slaty granite, on which, nearer the vertex, rested a clay slate, mixed with much mica. Towards the Puerto, he found a great change in the kinds of stone, such as clay slate with mica, sandstone slate, green marl, and between these, strata of carbonates, with traces of phosphates, of limestone, which is also found in strata in those mountains farther to the eastward. The sandstone is less slaty higher up the Puerto; and the summit is covered with ratchil. Towards Joraycego, on the other side, the clay slate and sand slate continue to the neighbourhood of Truxillo, the country around which is composed wholly of granite. Sand slate and clay slate were found near Mejadas, but the ratchil began about the venta del despoblado, which, at a village called San Pedro, formed rocks of a kind of breccia, extending along the Guadiana to Merida, from which the course of the river is through plains, or between gentle hills, as far as Badajoz, excepting a pretty high granite mountain on the south side of the Guadiana, near Merida. Soon after this hill a kind of sand breccia, and then a sandy plain as far as Merida.

Several of the Estremadura mountains, particularly that of Guadalupe, are covered with numerous medicinal plants. This mountain has several stage and roebucks. The principal mineral springs in the province, are those of Cheles, nine leagues from Talavera la Real; the Fuente de las Aguzaderas, near Zafra, upon the mountain Castellar; the Fuente dell' Carrasco, near the village of Almarrarin; the Fuente de Bernardo Estevard, near Barcarrota, a small town about seven leagues from Badajoz, and a quarter of a league out of the road from Xeres de los Cavalieros; and another by the side of the Hermitage of St Bartolome, near Alange, a town three leagues to the east of Merida. The first five of these are cold, and the last is thermal. It is very copious, and has baths, and was much frequented in the time of the Romans, the ruins of a basin and an oval edifice being still visible.

The Romans were attracted to this province by the soil and fertility of its soil, and the mildness of its climate; and agriculture, it was converted into a garden, by the industry of the Moors. Upon the expulsion of the Moors it was greatly depopulated, and since that time it has continued in a state of nearly total inutility to Spain. The soil is extremely rich; but it is almost completely reduced to the state of rank pasture. In the district of Badajoz alone, it is computed that there is a space of waste land 26 leagues long, by 12 broad. Neither gardens, nor orchards, nor fruit, nor mulberry trees, nor hemp, occur in the whole province. Wheat and rye are almost the sole productions, and the quantity grown is nearly sufficient for the support of a scanty population. Olive trees and vines are not numerous. Chesnut trees are more abundant, and afford nourishment to the inhabitants. Every autumn, about 4,000,000 head of sheep are sent into the provinces, and remain during the winter feeding upon the grass. Although agriculture is in this wretched state, yet there are some cantons where it is more flourishing. Gardens and fruit trees abound between the Puebla de la Cuzadaza and Montijo, in the Vera de Plasencia, &c. Olive trees are numerous at Banos; vines at Talavera la Vieja and Banos; and numerous plantations of oak, chestnut, and other trees, round Talavera, between Las Brozas and Arroyo del Puerco, in the Vera de Plasencia, and its valley, and near Ervas, Banos, and Bejar. Around Caceres and Plasencia, and in the valley of Bejar, agriculture is more attended to.

During several centuries, this province possessed some Manufactures of broad cloths, and other woollen stuffs. The principal manufactures which existed before the revolution, were one of hats at Badajoz, established by a Frenchman, two similar manufactories at Zafra, a number of tanyards at Zafra and at Caceres, and a manufactory of broad cloths at Arrago del Puerco. There is a manufactory of second cloths at Ervas, and another very considerable one at Bejar, which sends a quantity to Castile and Andalusia.

The roads and inns in Estremadura are very wretched. The road which leads into Portugal is the best kept, and was always repaired when any of the royal family of Spain and Portugal travelled that way. Link describes this road as more magnificent than any of the English roads, and better than most of the French.

There are neither schools nor establishments of any kind in Estremadura, excepting two colleges, the inhabitants being in a state of extreme ignorance.

This province contains three bishoprics, Badajoz, Plasencia, and Coria; three cathedral chapters in these three towns, 30 military commanderies, 415 parishes, 172 convents, 31 hospitals, 2 asylums, 2 colleges for the education of youth, 7 cities, 223 small towns, 94 villages, 1 grand military government, 11 particular military governments, 1 intendant at Badajos, and a royal audience at Caceres.

The chief towns are Badajoz, which is the capital, Plasencia, Coria, Merida, Truxillo, Xeros de los Cavalieros, Llerena, Almazan, Zafra, Caceres, Albuquerque, and Olivenza.
The principal rivers are the Tagus and the Guadiana, which are navigable, and other eighteen, viz., the Alagon, the Cuyar, the Sabor, the Savar, the Allegrate, the Alamonte, the Guyar, the Navazo, the Nalun, the Lentril, the Rivello, the Guadajera, the Cuya, the Mutachel, the Guadarranque, the Gevara, the Albarraga, and the Abrilongo.

The principal mountains are of considerable elevation, some of them being branches of the Sierra Constantina, in the centre of the kingdom of Seville, which it crosses from north-east to south, throwing out ramifications into the kingdom of Córdova, and joining the Sierra Morena on the north. The Sierra de Guadalupé is very high, and of great extent, and projects a number of branches into different parts of the province.

In the years 1787 and 1788, the province contained 416,922 inhabitants, consisting of

- Priests 2,441

- Monks 2,060
- Nuns 1,718
- Nobles 3,724
- Advocates 305
- Writers 505
- Students 1,416
- Servants 11,036

From this scanty population, the traveller often passes through immense tracts without seeing a settlement, a house, or a human being, and without perceiving a tree, or a spot of cultivated land. See Link's Travels in Portugal; and Laborde's View of Spain.

ESTREMOZ is a small fortified town of Portugal, in the province of Alentejo. The town is ill built, but has a large cheerful square in its centre. There is a castle on an eminence, and some outworks of no great importance. There are five religious houses in the town, and a sixth in the neighbourhood, an hospital, and a casa de misericordia. This town belongs to the corregimiento of Évora, but being a praça de armas, it has a governor. On the side of the town towards Lisbon, the country is well cultivated, and abounds in orange gardens and laurels, which continues as long as the soil is lime, but, on ascending the mountain, the soil consists of slaty granite, and all cultivation ceases.

A good marble is found in the neighbourhood of the town. There is here a small manufacture of earthenware. Population 6500.

ETAT MAJOR, in the French army, corresponding to the staff in ours, is composed of a number of select officers, and constitutes the grand medium for the arrangement and communication of orders. It transmits all instructions relative to the commission, and other branches of the interior service of the army; receives reports from detachments, from officers in garrisons, from spies, and, in short, from all officers on duty within the compass of the general's command. It is a receptacle likewise for the papers relating to prisoners and deserters, as well as for all certificates, and written applications. It issues orders of the day, plans of marches and engagements, and may be termed, in a comprehensive sense, the channel for the transmission of whatever requires the decision of a directing head, but is too much matter of detail to be transacted by the commander-in-chief. The chef of the etat major receives from the general-in-chief a summary of his directions respecting the movement and arrangement of the troops. These directions he extends and distributes to the head of each department, so as to convey the wishes of the commander-in-chief, and to preserve to the latter the disposal of his time for devising and combining plans of operation. The duties of head of the staff are so various as to constitute him the next man in importance to the general. His functions require a comprehensive knowledge of the principles and practice of war, as well as an accurate acquaintance with the scene of local operations. To these qualifications he must join indefatigable exertion, and a perspicuous method of communicating orders. He must be fully competent to answer the questions of the general in every point connected with the movements of the army.

It is now somewhat more than a century since the armies of Europe assumed a magnitude which required the constitution of an etat major as a distinct body. Various parts of the duty had been previously performed by particular officers; but it was under Louis XIV. and in the year 1672, that the establishment first received a separate form. In the succeeding reigns, various alterations and improvements were made; but such have been the extent of recent changes, that, at the time of the revolution, there were in a French army no fewer than three separate establishments, which divided among them the duties now performed by the collective etat major. The plan of proceeding has since then been so much improved, and the officers in this department so much better selected, that the military triumphs of the French have been, in a great measure, ascribed to the admirable constitution of this department of the service. A system completely regular governs all its operations. No sooner does the commander-in-chief communicate his orders to the chef of this department, than they are transmitted to the marshals commanding corps. Each corps of the French army has, moreover, its separate etat major, composed of a general of division and assistants, called Adjutants. There is even a third kind of etat major, viz. that of each division, the plan of which is, on a smaller scale, the same as that of the former.

From the time of commencing operations, the head of the staff in each corps of the French army keeps a journal of the proceedings, which is composed from the journals of the etats majors of divisions. This forms a narrative of the difficulties which have occurred, the advantages obtained, the losses, exploits, &c., with brief notices of the actual condition of the corps, its position, and the nature of the ground which it occupies. An abstract of this journal, made out in a clear and simple form, is given daily to an officer to be taken to head quarters, who repairs thither with all diligence, and with orders to deliver it to no one except the commander-in-chief, or the head of the staff. Each corps sends its extract at the same hour, so that the head of the staff is enabled to read and compare at once the different reports. The officer bringing the extract is expected to answer promptly all inquiries, and, if any particular corps has been forced to take a station unsuitable to the general plan, the deviation is corrected by the arrangements for the next day, which are drawn up on the receipt of the reports, and dispatched, in return, by the same officer. In addition to these daily communications, a list is transmitted, every third day, of the number of sick and wounded, and of those who remain fit for action. Frequency of correspondence continues the invariable rule, even when the different corps of an army are at a considerable distance. Special orders are given to afford every ac-
The routine of service for the French, as an example, is as follows: The officers are required to report at a given hour, and the air they are to travel on is at the distance of 80 or 100 miles. When a division is at rest, the officers are arranged in a group, and the engineer service is also present. While the latter requires extensive knowledge and accuracy of mathematical knowledge, the proper foundation for the officers consists in activity, good sense, and a practical familiarity with military affairs. Men of this character, though unacquainted with mathematics, are capable of reconnoitring at the head of a detachment of horse, and of directing the march of a column of infantry. The points required at their hands are accuracy of local knowledge, a correct acquaintance with the force placed under their command, and precision in the manner of making their report. The possession of gothic maps and plans is an object of first-rate importance; and to this the officers have long paid very close attention.

When we come, after all, to analyse this detail, we find nothing in it which might not, with proper pains, be equalled by the other nations of Europe. The rules prescribed are extremely simple, and the efficacy of the whole results from an accurate subdivision and a correct execution of the duties. The successes of the French have accordingly been owing to the concert and activity which prevailed in their movements, and in conjunction with the splendid talents of a few of their commanders. 

ETCHING, in the arts, is a species of engraving, produced by the action of an acid, or some other corrosive menstruum, upon metal, or other substances susceptible of corrosion. This term is, however, more particularly used, to express that peculiar effect produced upon copper-plate, by the action of dilute aquafortis, which, from its delicacy and softness of expression, has almost superseded the use of the graver. The prints, from plates which are merely etched, possess all the effect which the tool can give in point of strength; but the lines are not so deep as those formed by the tool, and, in consequence, soon become imperfect, from the wear of the plate in the act of printing. In order, therefore, to be enabled to take off a greater number of proofs impressions, the etched lines should be cut deeper by means of the graver. In such instances, the work is performed by the joint effect of the acid and the graver; and requires the hand of an excellent artist to apply the tool to the etched lines, without lessening their rich softness.

The plates of copper to be etched are prepared in the same way as those for engraving. The substances and tools essential to this process, are, first, a varnish to cover the whole surface to be engraved; second, etching needles, which should be made of cast-steel wire, about 1-1/2th of an inch in diameter. A variety of these are required, having points of different degrees of bluntness. The varnish is of two kinds, hard and soft; the former was in use in the early periods of the history of this art, when etching was deemed of no more importance than as an expeditious and easy mode of engraving, and practised by those only who could not guide the graver with professional skill. The soft varnish is now generally employed, being more calculated to produce the peculiar excellence of this sublime branch of art. The hard varnish is prepared as follows: Take equal parts of drying oil and mastic. The drying oil should be prepared from linseed oil, and kept till it acquires a certain degree of viscosity, under which it is said, by painters, to be fat. The oil should be heated in a stoneware dish, with a sand heat, and the mastic added in powder. The heat must now be kept up, and the mixture stirred, till the whole of the mastic is dissolved, and the compound becomes a uniform fluid. While yet hot, let it be strained through a fine linen bag, and bottled for use.

The following is the preparation of the soft varnish, as recommended by Le Boeuf: Take two parts of clear white bees' wax, and melt it in a stoneware vessel, in a sand heat. Then add to the hot wax, in fine powder, two parts of mastic; let it be added gradually, stirred all the time, and till it is thoroughly melted. Next add one part of asphaltum in similar powder, stirring as before, till it is completely dissolved. Let the liquid now cool, but not to lose its fluidity. Pour it into warm water, and mould it with the hands into sticks, or balls, for use.

The soft varnish used by Mr. Wilson Lowry, and prepared by himself, is as follows: He directs two parts of asphaltum to be melted in a glazed earthen vessel, with a moderate heat. To this is to be added one part of Burgundy pitch, and afterwards one part of white bees wax; the whole being stirred till the solution is complete. It is now poured into warm water, and worked into masses fit for use.

The copper-plate being prepared, and perfectly clean, is to be placed by the edge in a hand vice, which will serve as a handle. It is now to be heated over a glowing uniform fire, or what will be better, laid upon flat plates of metal heated by a sand bath. This heat must be so great as to melt the soft varnish. For this purpose, one of the balls or sticks, above-mentioned, must be wrapped in a piece of safetypaper. It is now to be drawn over the hot plate in successive stripes, till it is completely and uniformly covered. Still, however, the varnish will exhibit numerous ridges in the direction in which the ball was drawn over the plate. This will be got rid of by what is called a dodger, which is formed by wrapping a ball of cotton wool in a piece of Persian silk. While the varnish is still melted upon the plate, the dodger is pressed perpendicularly upon the plate, and withdrawn in the same direction. This will give the varnish an uniform smoothness. Immediately after this, the plate is to be placed with its varnished side downwards, and a flame, or large candle, held under it, but at such a distance as to smoke the plate without burning the varnish. The smoke, which is no more than lamp black, becomes incorporated with the varnish, making it completely black, by which means any lines transmitted to it, of a lighter shade, are rendered more conspicuous.

The next object is to transfer the design to the surface of the varnish, which is afterwards to be etched in the copper. Two methods are employed; an outline, or drawing, of the intended size, is first prepared in black lead pencil or red chalk. This, after being made damp by lying between two sheets of wet paper, is laid upon the plate with the drawn side downwards, and then passed through a rolling press. This will give a reversed impression of every line of the drawing upon the surface of the varnish; so that the intended print will be the same as the drawing.

The other method of transferring the outline to the plate, is by covering the back of the drawing with red lead, by rubbing on with a cushion, and rubbing it off again till it will not soil the fingers easily. This is
laid on the plate with the drawing upwards, pulling it tight, and fastening it at the edges. Every line in the drawing must now be traced with a blunt and smooth pointed needle, similar in form to those used in etching. During the tracing, nothing but the point must touch the plate. To ensure this, a board, called an etching-board, must be used. This is a thin board with a bevelled edge, and supported at each end, so as to form a bridge over the plate without touching it. Without this, the pressure of the hand upon the drawing would cause the varnish to be smeared with red lead, and thus render the outline indistinct. The whole of the lines being traced, the paper is to be removed, when the outline will be seen in the colour of the red lead.

If the surface of the varnish is coated with a paint-like composition of white lead and solution of glue, and the back of the drawing be covered with fine lamp-black instead of red lead, the outline produced by tracing will be in black lines, and very distinct.

The next process is to trace the lines marked upon the varnish with the etching needle. These, as has been observed, are formed of cast steel wire, about two inches long, and placed in little wood or ivory handles. The points, of which there are great variety, are formed and kept smooth and sharp by rubbing them lengthwise upon an oil-stone, causing the needle to revolve between the fingers as it is moved backwards and forwards. The same operation must be repeated upon a leather strap.

The lines are to be traced with needles of different degrees of fineness on the point, according to the fineness or strength of the lines in the design. This must be left entirely to the judgment of the artist. In landscape or figure etching, the justness of the work will depend upon the dexterity, judgment, and taste of the artist. When the lines are straight, parallel, and at equal distances, the correctness of the work may be much aided by a machine. This is particularly applicable to mechanical and architectural engravings, and has been carried to a surprising perfection by the talents of Mr. Wilson Lowry, who may be justly deemed the founder of a new school in this useful branch of engraving.

The point of the needle merely passes through the varnish, laying bare a portion of the copper equal to the breadth of the point. This being completed, the next thing is to prepare for applying the acid for etching the lines, or what is technically called biting in. The plate is first surrounded with a composition of bees-wax and pitch and tallow. This forms a kind of wall round the plate, about three-fourths of an inch high, and forms a recess or dish for holding the diluted acid. A lip or spout is formed at one corner for pouring off the liquor into a bottle, whenever it is thought proper to remove it from the plate.

The aquafortis employed is generally known by the name of refiner's aquafortis, which is generally weaker than what is sold for nitric acid. The first of these should be diluted with from two to three parts of water. The pure nitric acid would require more water. The strength of the liquor should, at any rate, be such as to produce a moderate effervescence with the copper. The acid liquor should be kept in a widish mouthed bottle, with a glass stopper, from which it may be easily poured on to the plate, and back into the bottle from the lip of wax in the corner.

On the first pouring of the liquor upon the plate, small bubbles of air will soon appear, as if emerging from the lines on the plate. The whole mass of liquid should be slightly agitated with a soft brush or a feather, for the purpose of facilitating the escape of the gas. This not only hastens the process, but renders the corrosion more uniform.

As soon as the finest lines are deemed sufficiently deep, the liquor is to be poured back into the bottle. The plate must now be well rinsed with water, and dried at a heat not capable of melting the wax or varnish. The plate is now examined, and those parts which are intended to possess the lightest shade, are to be what the artist calls stopped out. This is effected by a mixture of turpentine varnish and lamp-black, intimately ground together. Those lines which are sufficiently etched, are now to be covered with this varnish, by laying it on carefully with a camel-hair pencil. As soon as the varnish is a little hardened, the etching liquor is to be once more poured on the plate, observing the same treatment as before. When the corrosion has again proceeded till the next degree of shade is produced, it is again poured off, and treated as before. By this management, which depends entirely upon the skill and experience of the artist, the most delicate gradations of shade may be produced. When the corrosion is deemed sufficient in every part, the plate must be washed clean, and then uniformly heated to remove the wax from the sides. While the plate is still warm, it must be smeared over with oil of turpentine, or olive oil, or what is cheaper, spirit of tar. Any of these readily soften and dissolve the varnish, by which means it can easily be removed, and wiped clean with a soft cloth, or, what is better, carver's shavings. If, after this, any part should still be not sufficiently corroded, every other part must be again covered with varnish; the necessary being stopped out with the pencil and turpentine varnish. The acid liquor is now to be applied to the bare part, the plate being surrounded with wax as before. When the additional corrosion is apparent, the wax and varnish is to be removed, and the plate cleaned as before. This may be repeated as often as may be found necessary. The plate is now in a state to take prints from it. But it will be proper to observe, that if the etched lines are not gone over by the graver, or the dry point, the impressions will soon become imperfect from the wearing of the plate. Hence retouching is always necessary, when a great number of impressions have to be taken off. In many popular works, in which the sale is great, the plates require to be retouched several times, before all the required copies are taken off. Hence we see how desirable it would be to use some substance harder than copper for plates. Glass has been proposed for this purpose, but several objections in etching this substance render it impracticable. We do not know that polished hardened steel has been tried. The plates might first be hardened; without afterwards tempering them, they might be polished with great smoothness and accuracy, by machinery similar to that used for plate glass. That the acid would etch these plates as neatly as copper, cannot be doubted, when we recollect the beautiful ornaments put upon polished steel by etching, as we shall explain in the sequel of this article.

The etching with the hard varnish is performed in the same manner as with that already described. When the varnish is first laid on the plate, it requires to be held for some time over the fire, as the linseed oil requires some time to dry, and become stiff. When the smoking ceases, it may be removed. The sign of its being heated enough, is its acquiring such a degree of adhesiveness as to hold any thing fast that may be stuck to it. This trial is made in the margin, where no lines
ETCHING.

will be required. If the heat be continued too long, the varnish will become too hard, and will be apt to break off when scratched by the needle. In other respects, the treatment is the same as with soft varnish.

Another variety of etching is performed with what is called the soft ground, in imitation of chalk or black lead pencil sketches. The soft ground is prepared by melting a portion of fat oil, or, what is better, real suet, with the common etching ground, or soft varnish already described. The mass is to be wrapped in a piece of taffety, and laid on the warmed plate, precisely as directed in laying on the soft varnish, observing the same treatment afterwards. When the covering is cold, take a piece of thin paper, rather larger than the plate, and damp it. Apply it to the coated surface, and turning the edge on the other side, fasten them with gum or paste. When the paper is dry, it will become stretched quite tight. All that is now necessary, is to make a black lead or chalk drawing upon the paper, in the required style, observing not to touch the paper in any other place than the very lines in which the pencil should move; this may be effected by the bridge-like board, which we have already called an etching-board. When the drawing is finished, the paper must be carefully removed, taking hold of it by two corners, and gently raising these, till the opposite corners are liberated. It will be found, that wherever the pencil has pressed upon the paper, the ground will have adhered so firmly to it, that when removed, as had been directed, the ground will be brought away by the paper, from those parts intended to be etched. The ground, however, in these parts is not so entirely removed as it would have been with the etching needle, but a number of minute particles remain, which partially prevent the action of the acid, and thus give an effect to the print taken from such a plate the appearance of a sketch in chalk or black lead pencil. The roughness of the paper on which sketches are made, does not admit of the lines being completely covered with the lead or chalk; so that if one of these lines be viewed by a magnifying glass, it will appear a mixture of black and white spots, which gives the velvety softness peculiar to this style of drawing. The accidental and irregular manner in which surfaces traced by the pencil on the soft ground are covered with small particles of the ground occasioned by the pencil of the paper from the plate, produces an effect very similar in points of softness. The black paper being removed from the plate, the composition to keep the acid upon it must now be placed round the margin, exactly similar to what has been described in the common etching. The same rules must also be observed with respect to pouring off the acid from time to time for the purpose of stopping out, with the black varnish already mentioned in the common process.

It will be proper to observe, and will also appear obvious, that the accidental way in which this chalky effect is produced, will render it impossible to make any improvement in the etching, by any manual process, either with the graver or the dry point. The impressions should therefore be taken from the plate as the acid leaves it. See Aquatinta and Engraving.

A method of imitating sketchy drawings has been invented, which consists in making the etching upon any compact limestone, such as white marble. The stone being etched in these parts where more or less shade is required, the perfectly white parts corresponding with the polished part of the stone. The stone being wet and daubed with a printer's ball, the rough parts receiving the ink in proportion as they have been corroded, while the polished are left free. The paper being laid upon this, and pressure applied, will give an agreeable impression.

Messrs Brown and Mawe of Derby, and in the Strand, London, have lately introduced etching upon the very elegant articles which they form of various coloured marbles and gypsum. Vases and other ornaments are beautifully enriched with figures etched upon them by acids. If sulphuric acid of tolerable strength be laid upon polished gypsum, it gives to the part a dead white, which forms a good contrast with the polished part. For marbles or any carbonate of lime, the muriatic acid will answer best. The etching has an excellent effect upon black marble. It does not merely deaden the polish, but forms a greyish ground, which is not an agreeable contrast to the black polish.

Although glass plates do not answer for prints, etching has been employed to ornament glass with good effect. The corrosion of glass by the fluoric acid gives it the appearance of ground glass, so that when the figures formed upon glass are defended from the acid by any substance, the ground becomes opaque, forming a good contrast to the transparent part. The latter is generally painted representing figures or flowers, in the manner of painting transparencies. The common etching ground is generally used to cover the glass, in the same manner as the copper-plates are first coated, taking the same pains to spread it uniformly. When cold, the figures, but more commonly the ground, require to be formed partly by needles of different sizes; and a flat pointed tool when greater surfaces are to be removed. As soon as those parts intended to be corroded are cut out, they are surrounded with soft wax, as directed to be placed round the margin of the copper-plate, to form a recess for placing the acid. The etching is performed by three processes: 1. By the liquid acid; 2. By pounded fluor spar; and 3. By the acid gas, or what is more properly called the superfat of silex. The liquid acid is obtained by distilling the gas from fluit of lime and sulphuric acid, from a leaden retort into a receiver of the same metal, surrounded with ice, and containing a little water. The liquid obtained is to be employed on the glass in the same manner as the dilute nitric acid in etching copper-plates. The second method is the most simple, and is on that account generally practised. It consists in first precipitating the fluit of lime, commonly called fluor spar, and Blue John, to powder. When the sides of the outlined plate are surrounded with wax to about three-fourths of an inch high, the powdered fluor spar is to be spread upon the plate in a uniform stratum about 5-10ths of an inch thick. The remainder of the cavity must now be filled with diluted sulphuric acid, the water being to the acid as about three to one by weight. It must be placed in a warm situation, but not so hot as to melt the wax or varnish. The sulphuric acid soon begins to liberate the fluor acid, which in its nascent state corrodes the glass. The gas which escapes carries the silex of the glass along with it in the form of superfat of silex. The fluit of lime used for this purpose should be very pure, that is, free from silex. If the latter be present, the acid will be apt to escape with it, instead of getting the silex from the glass, by which it becomes corroded. The same evil occurs when the bodies to be corroded are exposed to the gas in which silex is present, because it is already saturated with what it should take from the glass. The fluoric acid free from silex
The art of etching upon steel, has been practiced at Shefield and Birmingham for ornamenting polished steel. The corroded plate becomes a dead white, while the part unaffected remains polished. Those parts intended to be preserved from the acid, are drawn with turpentine varnish, while that which is to form the white ground is left bare. The space where the acid is to be exposed, is first surrounded by a wall, of a mixture of bees wax and pitch, with the addition of a little tallow. The acid employed is the nitric, diluted with 3 or 4 parts of water, more or less according to the strength of the acid. The proportions will be those which produce the whitest ground. This will be easily formed, by trying different strengths of acid, with a pair of polished steel tips kept for the purpose. This beautiful art is much assisted by bluing and gilding. (c. s.)

**ETON, or EATON, the name of a large village in the county of Buckingham, consisting of a single street, pleasantly situated on the north bank of the Thames, and connected with Windsor by a bridge. This village has long been celebrated for its public seminary, in which many of the distinguished characters in the kingdom have received their education. Eton College was founded in 1440, by Henry VI. for a "provost, ten priests, six clerks, six choristers, 25 poor grammar scholars, with a master to teach them, and 25 poor old men." It now supports a provost, seven fellows, two schoolmasters, two cadets, seven clerks, 70 scholars, and 10 choristers, with various other officers and assistants. Twelve of these scholars are annually elected to King's College, Cambridge, to which they are removed, according to their seniority, as soon as any vacancy occurs, the average number of vacancies being about nine in two years. They are entitled to a fellowship, after having continued there three years. Two scholars are also sent annually to Merton College, Oxford, where they are named Postmasters.**

At the age of 19 the scholars are superannuated, and for their benefit there are a few exhibitions of 21 guineas each, which has been increased by a legacy of £60 per annum, bequeathed by a late fellow, Mr Chamberlayne.

Besides the king's scholars, there are generally from 300 to 350 independent scholars, or undergraduates, as they are called, educated here. They are the sons of noblemen and gentlemen, and reside at lodging houses within the bounds of the college.

Eton College consists of two courts or quadrangles, divided by a handsome tower or gateway. In one of these is the school, the chapel, and lodgings for the masters and scholars. The school is divided into the lower and upper, each of which is subdivided into three classes. The other quadrangle is occupied by the library, the provost's lodgings, which are in the front, and the fellows' apartments. The library, which is on the south side, is one of the best and most elegant in the kingdom, both with respect to its architecture and its collection of books. The books were bequeathed to it principally by Dr Waddington, bishop of Cichester, Dr Godolphin, provost, Nicolas Mann, Esq. late master of the Charter-house, and Richard Topham, Esq. of Windsor. This last gentleman also left many elegant drawings of Greek and Roman antiquities, collected by himself at Rome, at great expense; An excellent collection of books was likewise bequeathed to the library, by a late fellow of the college, Mr Hetherington, who also erected, at his own expense, a neat chapel in the middle of the town for the accommodation of the inhabitants.

The college chapel, which is on the south side, is a very handsome building, ornamented with large abutments, pinnacles, and embrasures, and has sometimes been compared to the chapel of King's College, Cambridge, to which it is, however, much inferior in internal decoration. It is 175 feet long, including the antichapel, which is 62 feet long. In the antichapel is the statue of the founder, by Bacon, which was erected in 1766; and a monument of the young Earl of Waldegrave, who was drowned in 1794, when at Eton school.

A singular custom, known by the name of Montem, takes place every third year on Whit-Tuesday. All the scholars, &c. march in procession with music and colours to a tumulus, which has received the name of Salts-hill. The object of this custom is to collect what is called Salt Money, which is done by the salt-bearers and scouts dressed in different coloured silks. The salt money has sometimes amounted to £800, from the liberality of the king and the royal family; and this sum is given to the captain, or senior scholar on the king's foundation, for the purpose of supporting him at the university of Cambridge. See Gough's Camden's Britannia, and Beauties of England and Wales, vol. i. p. 398 (w).

**ETYMOLOGY, (from the Greek etymos, true, or real, and logos, speech.) the science which investigates the nature, origin, derivation, and formation of words. The subject of etymology being words spoken or written, it may be viewed under two aspects: 1st, As forming a part of particular grammar; 2d, As constituting a branch of the philosophy of language. In the former, the office of etymology is to mark out the different classes of words, or parts of speech, as they are usually termed; the purposes which these respectively serve; the inflections or changes which they may undergo; and the modes in which, by composition or de-**
ETYMOLOGY.

In the latter, the etymologist extends his views beyond mere grammatical formations, to the remote and reconcile analysis of words, whether primitive or derived, with a view to trace out the actual origin, progress, and filiation of languages, and, if possible, to discover the radical nuclei or germs of human speech, as expressive of human thought. The elucidation of the first branch belongs to grammarians and lexicographers; the second forms an interesting subject of philosophical enquiry.

Considered under either point of view, the importance of the study of etymology cannot justly be called in question. As a part of particular grammar, it constitutes a fundamental and essential branch of it, absolutely necessary for the knowledge of the language, and essentially requisite for attaining either precision of thought, or accuracy of expression. As an object of scientific research, etymological discussions, temperately conducted, may contribute much to our acquaintance with the intellectual faculties; throw light on obscure points of history, or national antiquities; or present many curious facts respecting the progress of human knowledge,—they certainly cannot, as some have absurdly maintained, discourse to us the essence of things, but they may at least furnish assistance towards unfolding the actions of the mind in observing and discovering the objects affecting it. Prejudices have indeed been entertained against researches of this description, as if they were founded upon no certain principles, but resting merely upon arbitrary conjecture, were consequently unfit to lead to satisfactory results. But this objection applies not to the nature of the subject, but to the mode in which the investigation of it has sometimes been conducted. If fanciful analogies are allowed to usurp the place of rational observation, etymological discussions may no doubt present a mass of learned absurdities; but when conducted upon comprehensive and philosophical views, and confined within their just and appropriate limits, they may lead to conclusions gratifying to the inquisitive mind, and beneficial to science at large.

For the conducting of etymological enquiries, it is not easy to lay down very specific rules; but some general principles may be mentioned.

In studying or explaining the etymology of any particular language, the nature and genius of the language itself must regulate the mode of proceeding. There are, however, general principles essential to the expression of thought, and consequently common to all languages. Speech is the expression, by articulate sounds, of our internal thoughts and feelings; now, as the operations of the human mind are uniform in similar circumstances, language, wherever formed and introduced, must have proceeded in a track so far uniform, that at least the constituent parts of all languages must be in reality the same, though, perhaps the characters of each part may be more distinctly marked in some than in others. In some, many of the more common relations of objects, or modifications of action, are expressed by minute but significant changes or inflections of the radical word; in others, the changes of the radical word are few, its multiplications, or modifications, being denoted by supplementary terms, or by peculiar collocation. The ancient Greek and Latin languages are examples of the former; most of the languages of modern Europe of the latter. According to the peculiar structure of the language in these points, a corresponding difference takes places in the character of its etymology, more refined and complex in some, more simple in others. Where many relations and circumstances are expressed by means of inflection, that branch of etymology which treats of it, must become an important and fundamental object of attention. Such a language possesses this advantage, that when the laws of its inflection are understood, and the radical meaning of the verb or noun comprehended, each word, whatever place it may occupy in the sentence, has its precise relation to the others ascertained. In languages of less artificial structure, where recourse must be had to supplementary terms, much of the sense must depend upon collocation alone. Languages of the former description are more susceptible of variety of arrangement, as well as harmony of modulation; in languages of the latter kind, the arrangement is necessarily more confined and uniform, but it has been thought that accuracy and perspicuity are thereby better attained.

In what manner these varieties in the etymological structure of languages have arisen, has been a subject of dispute. Some have supposed that inflections had their origin from the gradual junction and amalgamation of separate terms with the radical word: thus, in nouns, the terms denoting species, recipient, or subject of action; and in verbs, the terms expressing time, volition, command, or dependence, being frequently in common use pronounced along with the word to which they related, came at length to coalesce entirely with the radical word, and to form the genitive, dative, and accusative cases of nouns, the tenes, mood, or voices of verbs, changes that might easily arise when a language was constantly employed by an active, ingenious, and animated people. To others it has appeared more probable, that the progress of language was in a different direction; that speech being intended to communicate the complex feelings and impressions of the mind, at first consisted of what may be denominated mere masses of sound, significant only of these complex impressions, in which substance, qualities, and actions were united and blended without distinction; that, by the operation of external objects, a modification of these impressions taking place, and the agent, the action, the effect, and the quality, becoming alternately objects of direct and specific attention, a corresponding variation to indicate these modifications, took place in the significant sounds; that separate classes of sounds significant or words, being thus formed, further but minute variations upon these words themselves were found necessary, to denote the relations in which they were supposed to stand, or the particular mode of operation they were believed to exert: These it was easy to supply by abbreviation, adjectives, or more emphatical enunciation, at the commencement or termination; and in this manner might be formed the cases of nouns—the tenes, moods, and persons of verbs; from which afterwards might arise, by separation of a part, or contraction of the whole, new classes of words, denoting relation, position, or modification in general, and constituting the classes of adverbs, prepositions, and conjunctions.

In which of these two tracks we are to look for the actual progress of language, is a question perhaps incapable of complete solution, nor, as relating merely to the study of etymology, is it very material to determine it. It will be sufficient for the etymological student, in the first place, to ascertain how far the language to which his attention is turned, partakes of the more simple or more complicated structure, and then to direct his labours so as to obtain an accurate and
ETYMOLGY.

The second branch of etymology has for its object the analysis and resolution of words, with a view to discover their remote origin, the filiation of languages, or the primitive germ of human speech. For the successful prosecution of this study, a comprehensive view of the nature of language in general, in regard to its object, its constituent parts, and the principles of its formation, is first of all necessary, that no particular analysis may be brought forward inconsistent with the fundamental principles which must operate in all languages. Keeping these in view, and observing accurately the structure and forms of words in the language to be analyzed, it will not be difficult, especially in those of regular fabric, to distinguish, with sufficient precision, the radical and primitive parts, from what are only necessary and accidental. If the modes of derivation and composition are found to be uniform,—if the derivations words can all be traced to primitives in the language itself,—and if these primitives can be ultimately resolved into roots, evidently existing in and proper to it, we may, without hesitation, assign to that language the title of primitive, and accordingly proceed in our attempts to delineate its remote constituent parts, and the laws of its formation and structure. Such we find to be the case in the Hebrew, the Ancient Gothic, the Sanscrit, and some others. If, on analyzing a language, we find all these distinguishing features, we may justly regard it, in an etymological view at least, as a primitive, although the similarity of many of its words to those of another might seem to indicate a derivation; in this case, both languages may have been branches from the same root, or one of them, in all its parts, and in its native form, transplanted into a new soil, and there retaining all its roots, with their earlier ramifications unchanged, may afterwards have germinated into branches peculiar to itself. Of this the Greek affords an example. Transplanted probably at first from Phoenicia in the form of the Old Pelagic, it still retained, in its new country, the primeval roots, from which in time emanated, by regular progress, a new and copious language,—a language, however, in which all the words are found to be formed from significant roots still existing within it: The title of a primitive language may, therefore, with propriety, be given to it.

If, on the other hand, a language were to exhibit these characteristic features of a primitive structure, it falls to be regarded as a derivative, and analyzed accordingly, with constant reference to the sources from which its words have originated. To this class it is probable the greater part of the languages now existing belong; and the investigation of their formation and affinities affords by far the widest field for the labours of the etymologist. In the course of such researches, interesting facts are often disclosed, evincing at once the filiation of languages, and the common origin of nations; and though the examination of languages alone, when other documents are wanting, will not go far in the elucidation of historic facts, yet etymological enquiries, judiciously conducted, may afford useful aid for judging of the credibility of the details of remoter periods.

In carrying on such etymological enquiries, attention should first be paid to the languages in which the real primitives are to be found. Thus in analysing the modern English, the Anglo-Saxon, the Greek, the Latin, must all be referred to, as each of these have contributed something to the present stock, and without a knowledge of each, the investigation must be very incomplete. In the actual deduction of the words as they occur, discriminating attention is often required. Sometimes, indeed, the origin is too manifest to admit of doubt. Terms of art, ecclesiastical denominations, and forensic phrases, if transplanted from one language to another, generally bear such manifest marks of their peculiar origin, that they can at once be referred to their primitives; but nouns and verbs in common use, particles, prepositions, and conjunctions, are often changed in passing from one people to another, that it requires an accurate scrutiny before we can ascertain their parent stem. In such cases, various circumstances call for attention. The successive revolutions in the language which we are attempting to analyse should be studied; changes, both in orthography and in pronunciation, gradually taking place, and these sometimes so considerable, that without remounting to the earlier stages, the connecting links would quite disappear. The varieties of enunciation even of the same words, particularly in the vowels, which accident may have introduced, and habit continued; the interchange of consonants of the same order, as certain organs of speech in different countries are more or less exercised, and the alteration of letters for the sake of more harmonious sound, are all of them fruitful sources of apparent discrepancy, in words of similar origin and import; while, at the same time, metaphorical applications, restricted senses, and analogical modifications, are no less apt to produce great variations in meaning. All these it is the business of a skilful etymologist to analyse, till the primitive word can be traced through all its changes. Examples of all kinds may be found in every modern dictionary. While the etymologist, by attention to these circumstances, can proceed successfully in his labours, great caution is necessary, on the other hand, to avoid the fanciful and absurd deductions in which lexicographers and antiquarians have too rashly indulged. Etymologies far-fetched, or built upon resemblances purely accidental, ought in general to be disregarded; and unless historical circumstances can be traced, sufficient at least to render the supposed connection or descent probable, if not certain, a few similarities of speech would be too weak a foundation for a system of filiation. Occasional coincidences may arise in languages quite unconnected, and which have no radical affinity; it is only when, by following up the analysis, we can trace the resemblance in the radical stems, that we are warranted to infer the actual descent.

Upon the principles now laid down, etymological enquiries into the structure of different languages might be conducted with success, proceeding by a strict inductive process from the derivative languages actually existing, to the remoter primitive tongues, which furnished the roots whence these have gradually emanated. When arrived at these primitive languages, it might still be an object of curious research to continue the investigation, and endeavour to analyse these primitive languages themselves, till some view could be obtained of the first elements, and subsequent progress of human speech. In every primitive language, it seems by no means improbable, that the roots could be fully investigated upon just and philosophical principles of etymology, and the application of
the elemental sounds in the formation of each distinctly marked out, a peculiar and specific idea would be found attached to the use of every individual consonant, prevailing in some form or other, through all the subsequent ramifications. Not that the general idea could be in view when the words were formed, but that the generalisation arose from the repeated application of the sounds, and not from the expressions individual to each, or individual feelings, concurring in the same common quality. By such an analysis, a theory of language might be formed, according with the progress of nature, and an excellent track would be opened, for tracing the procedure of the human intellect in the arrangement of ideas and formation of speech. A comparison of these primitive roots, too, would best enable us to determine what degree of affinity existed among the languages to which they belong, and, perhaps, throw some light on the much-agitated question, whether all the languages of the world were really derived from one. Probable as the opinion of their common origin must be allowed to be, and strengthened by many striking proofs of actual coincidence, still, to establish it completely, such evidence seems to be wanting, as a radical analysis, upon the principles now mentioned, alone could furnish.

Etymology has chiefly been cultivated by lexicographers and grammarians, a class of writers too numerous to be particularized. Philosophical etymology has principally been studied by the moderns; a few examples of it occur in the writings of Plato and Aristotle; and in some of the works of the Platonists of the Alexandrian school, but these are only incidentally and not systematically touched upon. In modern times, some of the Dutch philologists, particularly Hemsterhuis and his disciples, have distinguished themselves in this line. Horne Tooke has thrown great light on English etymology, and Dr Jamieson has furnished much valuable information on that of the Northern languages. The expected work of Dr Murray on the languages of Europe, there is reason to hope, will prove a most valuable acquisition to the lovers of etymological research.

**EVAPORATION.** is the process by which the aqueous particles of bodies are converted into vapour. This process is of two kinds, Artificial, and Natural or Spontaneous. We have already described the general appearances connected with the former, (See Chemistry, p. 37.), and we shall therefore confine our attention at present to the consideration of the latter.

Spontaneous evaporation is promoted by a variety of causes, of which the principal appear to be elevation of temperature, and the successive application of fresh portions of air. Neither of these circumstances, however, can be deemed essentially necessary to the process; since ice gradually wastes away at a very reduced temperature, and even more rapidly under an exhausted receiver, than when it is exposed to a current of atmospheric air.

Various theories have been proposed, with the view of explaining the conversion of water into vapour, at natural temperatures, and its subsequent elevation in the atmosphere; but notwithstanding the frequency with which the process is presented to our observation, and the important purposes which it is destined to serve in the economy of nature, there are few subjects of philosophical enquiry involved in greater obscurity. According to Des Cartes, the action of the sun upon the water converts small particles of that fluid into hollow spheres, which, being filled with a subtil matter, are rendered specifically lighter than air, and thus ascend in the atmosphere. Desaguliers, assuming the hypothesis that heat sets more powerfully on water than on common air, asserts that at a temperature which by its cold condenses air, may be sufficient to cause an evaporation from water, or even from ice. He further assumes, that the particles of water, after they are converted into vapour, acquire a repellency to one another, and deriving elasticity from the contiguous air, recede farther and farther till the specific gravity of the fluid which they form becomes lighter than air, after which they ascend. The particles of the vapour are supposed to retain their repellant force till by the diminution of the density of the surrounding air, their relative weight is increased, and they again descend in the form of rain, hail, &c.

A theory somewhat similar to this has been supported, with much ingenuity, by Dalton and De Luc. These philosophers maintain, that since water passes readily into vapour in vacuo, where the agency of the air is completely excluded, its spontaneous evaporation in the atmosphere may be referred entirely to the operation of caloric. Accordingly, Mr Dalton, agreeably to his opinion respecting the constitution of the atmosphere, asserts, that the aqueous vapour, thus formed by heat alone, exists in air, not in a state of combination with it, but merely of mixture or diffusion; that it exerts no action whatever with the surrounding gases, but supports itself entirely by its own elasticity; and that the quantity of it depends entirely upon the temperature of the air, and the pressure exerted by the vapour already formed. He even advances a step beyond this, and affirms that the quantity of vapour which could exist in the atmosphere would be the same, though the pressure of the atmosphere did not exist, as the vapour itself would soon accumulate, and form an atmosphere which would produce on the surface of liquids all the mechanical effects of the air itself.

The principal argument which Mr Dalton has brought forward in support of his theory, is drawn from the well-known fact, that water passes readily into vapour under an exhausted receiver, and where, since there is no air present, the evaporation must be ascribed entirely to the influence of caloric. Dr Murray has shown, however, that it by no means follows, because water passes into vapour in vacuo, at a natural temperature, it will pass into vapour to the same extent, at the same temperature, under the ordinary pressure of the atmosphere. The two cases are indeed totally different. When water is placed in vacuo, evaporation cannot, it must be admitted, be owing to the presence of air; but it ought to be recollected, that when the air is removed, its mechanical pressure is removed along with it; and it would be altogether illogical to conclude, that because water passes into vapour in the absence of that pressure, it would do so in an equal degree when exposed to it. "The proper manner of making the experiment," as Dr Murray very properly remarks, "is to exclude the chemical agency of the air, while the pressure of it is preserved; in other words, to place water in vacuo under the pressure of a column of mercury 29 inches in height, which is equal to the pressure of the atmosphere. If in this case any vapour were formed, the conclusion would be just, that spontaneous evaporation is independent of any chemical agency of atmospheric air. But the fact will be found very different; for although water introduced into the tube of the
barometer at 60°; because to vapour, and depresses the mercury half an inch, that vapour will be completely condensed, and the water retained in the fluid form by a pressure a little greater, instead of being able to exist under the pressure, which is equal to that of a column of mercury 29 inches high. Mr. Dalton has endeavoured to repel this objection, by maintaining, what appears to be quite inconsistent with fact, that pressure does not prevent the evaporation of fluids, or at least, that the pressure of the atmosphere is exerted in such a way as to allow, by its partial action, the escape of some of the particles of fluids: for, according to his opinion, *it is not till the depth of ten or twelve strata of particles of any liquid, that the pressure upon each perpendicular column becomes uniform; and that several of the particles in the uppermost stratum are in reality subject to but little pressure.* It is unnecessary to observe that this assertion is entirely hypothetical, and even at variance with the known laws of hydrostatics.

The hypothesis, however, receives some degree of support from the alleged fact, that the same quantity of water vapour is contained in equal volumes of different gases saturated with moisture. Saussure ascertained this to be the case with common air, carbonic acid, and hydrogen gas, or rather that these gases exhibited, in the same circumstances, the same hydroscopic condition. Clement and Desormes were also led, by their experiments to infer that all gases contain, under similar circumstances, equal portions of water. It was even stated by Saussure, and the assertion was afterwards repeated by De Luc and Dalton, that the quantity of watery vapour contained in any gas is the same as that which would be contained in a vacuum of equal extent with the space occupied by the gas. These facts, if admitted, seem to favour the opinion that water is converted into vapour, and retained in that state, not by an affinity subsisting between the water and the gas, (for it is not likely that this affinity should be the same with all the gases,) but merely by the watery vapour being raised by the action of caloric, and afterwards diffusing itself mechanically by its own elasticity.

On the other hand, it may be said, that the accuracy of these facts is, from their extreme delicacy, very questionable; particularly as they have rather been deduced by inference, than proved by direct experiment. A portion of water is allowed to be converted into vapour in vacuo, and the depression which it produces upon a column of mercuury, is assumed as the measure of its elasticity: a quantity of dry air is also introduced into a receiver of equal capacity with that in which the vacuum was formed, and an equal portion of water is introduced, the temperature in both cases being the same. The acquired elasticity of the vapour, indicated by the effects of its pressure upon the mercury in an inlosed barometer, is the same as that in the vacuum, and produces an elevation of half an inch, at the temperature of 60°. It is therefore concluded, that an equal quantity of water has in all these cases been converted into vapour. But, in opposition to this conclusion, it has been said, that the elasticity exerted by the vapour under these different circumstances, is not an exact test of its quantity, unless it be admitted that the vapour is not all attracted by the gases; and this is the very point to be established. If the vapour be combined with the gas, its elasticity will be counteracted in a degree proportional to the attraction exerted; and it is easy to conceive, that, at the point of saturation, the elasticity may be so modified by the power of affinity, as to indicate the same degree of intensity, though the quantities of vapour which are present be very different.

But it has also been urged, in support of this theory, that the quantity of moisture deposited by equal volumes of different gases in a saturated state, is, in all cases, the same when they are exposed to substances which have a strong attraction for water. Clement and Desormes established this fact by experiment with atmospheric air, oxygen, hydrogen, nitrogen, and carbonic acid gas; the differences in result being so small as might naturally be expected from the mode of performing the experiments. But though the argument afforded by these experiments, in support of the opinion that the vapour exerts no action with the gases, must be admitted to be of some weight, it cannot be regarded as perfectly conclusive; since it still remains to be determined, whether the quantities of water, which cannot be taken from the different gases by desiccation, are exactly equal; and there appears to be no means of ascertaining this by direct experiment.

It cannot be doubted, that the gases do differ from one another, with respect to their affinity for water; since unequal quantities of them are absorbed by that fluid under equal degrees of pressure; and though this affinity may be diminished when the water exists in a vaporous state, it is probably never entirely subverted. Upon the whole, then, it may be concluded, that the facts which have been stated are not incompatible with the opinion, that spontaneous evaporation is produced by a mutual affinity subsisting between air and water. This opinion, which is the one generally received, was first suggested by Dr. Halley; it was afterwards adopted by Dr. Franklin, and has been ably supported by M. Le Roi, Dr. Hamilton, Dr. Murray, &c. That a chemical attraction does exist between water and atmospheric air, is proved by the fact, that water absorbs a certain portion of its component gases, and retains them in combination with considerable force; and every kind of attraction being mutual, air must also be capable of dissolving water in a degree depending upon this affinity, though modified, no doubt, by the elasticity of the vapour which is formed. Mr. Dalton maintains, that the combination is entirely mechanical; and that the absorbed gas received into the vacant spaces, between the particles of the water, is retained there without the aid of chemical attraction. This opinion is somewhat countenanced by the discovery of Dr. Henry, respecting the law by which the absorption of gases is regulated. This very able and accurate chemist found, that the temperature being the same, the quantity of any gas absorbed by water, was exactly proportional to the pressure to which it was subjected, or, to use his own words, that *under equal circumstances of temperature, water takes up, in all cases, the same volume of condensed gas, as of gas under ordinary pressure.* But admitting the law, as Dr. Murray has stated with his usual ingenuity, the conclusion does not follow which has been drawn from it. "In the absorption of gas by water, two powers operate, or may be conceived to operate, independent of pressure—the affinity between the gas and water tending to combine them, and the elasticity of the gas counteracting this, and placing limits to the combination—precisely in the same manner as in the solution of a solid, there are two forces operating, the chemical affinity, and the cohesion of the solid. In the absorption of a gas, whatever favours the exertion of the elasticity will lessen the quantity absorbed; whatever represses it, will promote the absorption. These effects are produced by varia-
EVAPORATION.

219

Evaporation.

The principal objection which has been offered against the theory that evaporation is owing to a chemical solution of water by air, is, that according to that supposition, the process ought to go on most briskly, when the air is in a condensed state; but the very reverse is the case. But this objection may be answered by saying, although the quantity of air, which is thus brought in contact with the water, is increased, its pressure is increased in an equal degree; and the effect of quantity may be more than counteracted by the increased difficulty which the water now has to overcome in assuming the vapourous state. On the whole, therefore, we are disposed to think, that no argument has been urged against this theory, of sufficient force to invalidate its truth; and since a variety of facts, both of a direct and analogical kind, conspire to give it support, we consider it as affording a more satisfactory explanation of the process of spontaneous evaporation than any which has been proposed. We shall, therefore, now proceed to illustrate the nature of the operations, by which the aqueous vapour is supposed to be elevated into the higher regions of the atmosphere. The cause of solution being the stronger attraction of water for air, than for its own particles, the part already dissolved will, in consequence of the superior affinity of the less saturated portion of air immediately above it, gradually diffuse itself, and thus allow the lower strata, in contrast with the fluid, to dissolve an additional quantity. The process, like the solution of a salt in the bottom of a vessel of water, will go on very slowly when the solvent is not exposed to any agitation; and, accordingly, it is well known, that evaporation is greatly promoted by wind, which brings a continual current of fresh air, while it carries off the portion of it already saturated with moisture. The water being thus converted into vapour, and gradually elevated into the higher and colder regions of the atmosphere, is partially condensed, and gives rise to all the diversified appearances which we call clouds, mists, fogs, &c. These appearances take place at different heights in the atmosphere, according to the temperature of the air, and the quantity of water which it holds in solution. Hence we can perceive the reason why clouds are higher in summer than in winter; and why a lowering atmosphere generally announces the approach of rain, as it indicates the air to be so copiously loaded with moisture, that the reduction of temperature produced by a very small elevation, is sufficient to condense the excess of water, which the air is unable to dissolve. When different strata of air, saturated with moisture, but at different temperatures, are mixed together, by winds or any other cause, a precipitation of water must be the consequence; for it has been ascertained, that the solving power of air increases in a faster ratio than the temperature. This is well illustrated by the great quantity of rain which falls in mountainous districts, compared with that in flat and extensive plains. If the strata of air which are mixed together be in a state of complete saturation, and differ considerably in temperature, the quantity of water precipitated will be very copious: this may be expected to hold particularly when the strata are in opposite states of electricity, and thus mix rapidly and thoroughly together; hence the reason of the very heavy showers which usually accompany thunder storms. If the temperature of the atmosphere where the condensation takes place be sufficient to freeze the watery particles as they are formed, snow is produced; but if they have time to collect into drops before they are frozen, they become hailstones. Southerly winds are commonly followed by rain, because being warm, and saturated with aqueous vapour, they are cooled by coming into a colder climate; while northerly winds, by being exactly in an opposite condition, are dry and parching, and usually attended with fine weather. When the atmosphere is completely saturated with moisture, and passes from a rarer state, it suffers a diminution of temperature by its increased capacity for caloric, and being unable to hold the same quantity of water in solution, it deposits a portion of it. It is owing to the same cause that a mist or cloud is formed upon exhausting a receiver with the air pump; and in like manner may be explained the reason why fogs usually cover the tops of hills when a current of air, loaded with moisture, is driven over them. The air, which is perfectly transparent at the bottom of the valleys, because its temperature is sufficient to make it dissolve completely the moisture with which it is charged, becomes opaque in the more elevated regions, on account of the reduction of temperature which it undergoes, partly from change of position in the atmosphere, and partly from rarefaction in consequence of that change. On the contrary, when the atmosphere passes from a rarer to a more condensed state, instead of depositing moisture, its solving power is increased; and it dissolves either wholly or partially, the clouds which may have been previously formed. This is one reason why the rising and falling of the mercury in the barometer become indications of the state of the weather.

Dr Halley attempted to ascertain the quantity which evaporates from the surface of water, in natural temperatures, by exposing a circular surface of about eight inches diameter, to a heat equal to that of a summer's day, and found it to be at the rate of six ounces in 24 hours, or $\frac{1}{4}$th of an inch deep in 12 hours. By this experiment, each square foot of surface yields in vapour daily about half a wine pint; a square mile 6900 tons; a square degree 33 millions of tons. (Phil. Trans. No. 189.) A surface of eight square inches, evaporated by the natural temperature of the air, without exposure to wind or sun, in the course of a whole year, 16292 grains of water, or about 64 cubic inches; consequently the depth of water evaporated in that time was eight inches. Such experiments, however, are of little value; and no general conclusion can be drawn from them respecting the average quantity evaporated from the surface of the earth. The experiments of Mr Hoyle and Mr Dalton were conducted with greater precision; but still they must be regarded as only of local application. A cylindrical vessel of tinned iron, ten inches in diameter, and three feet deep, having tubes soldered to it for conveying off into bottles the water which it received, was buried in the ground in an open situation, and then filled with gravel, sand, and soil. The whole being covered with grass, and other vegetables, it was allowed to receive the rain, and to suffer evaporation from the surface, as in ordinary circumstances. A register was kept of the water which made its way through the soil into the bottles; and a rain gauge of equal surface was placed close by, for the sake of comparison. The following Table exhibits the results ev-

Quantity of evaporation from the surface of water.

| Experiment of Mr Hoyle and Mr Dalton. |
Evaporation.

The writer of this article, employed the following method of discovering, by evaporation, the quantity of latent caloric existing in steam or vapour. A quantity of pure water, equal in weight to 550 grains, was placed in a small glass cup, weighing 440.08 grains, along with a pocket thermometer, the weight of which was 59.32 grains. The whole was disposed as in the experiment described under the article Cold, p. 794; and the exhaustion was then carried on slowly and cautiously, to prevent any part of the water from sparkling over, by too violent an ebullition. In four minutes the water was reduced in temperature from 47° to 30°; and on the air being admitted, was found to have lost 12.75 by evaporation. It was ascertained, by a calculation founded upon the mean result of several experiments, that the thermometer and the cup which contained the water, would, in point of temperature, have produced the same effect as 130 grains of water; so that the whole quantity of water cooled down might be considered as equal to 550 + 130 = 12.75, or 667.25 grains. This gives \( \frac{12.75}{667.25} \) or \( \frac{1}{52} \) as the ratio of the portion of water evaporated, to that cooled down from 47° to 30°.

Having stated the results of these experiments, we may mention, that the process of forming ice in the East Indies, when the temperature of the air is above the freezing point, by exposing water in shallow unglazed earthen vessels, has been usually explained by ascribing the reduction of temperature to the evaporation of the water; and that this must, in many cases, contribute to the effect, cannot be doubted, since the evaporation of \( \frac{1}{46} \)th part of the water exposed, if the process were instantaneous, would be capable of reducing its temperature 10°. But Dr Wells, in his Essay on Dew, has endeavoured to show, that the principal share of the effect is owing to radiation. By exposing water, in circumstances similar to those in which ice is formed in Bengal, this gentleman observed, that the water, instead of suffering a loss of elevation by evaporation, became, in some cases, actually heavier by the deposition of moisture from the atmosphere; so that, in such instances, the effect of evaporation in cooling the water, must have been more than counteracted by the caloric imparted by the condensed vapour. One experiment on this subject which he relates, was performed on the evening of the 16th of October. With the view of imitating the method of making ice in the East Indies, he caused a pit, 4 feet long, 3 feet wide, and 2 feet deep, to be dug in the middle of a garden, and clean dry straw to be afterwards strewn to the height of a foot over the bottom of it. On the straw were next placed a number of small shallow earthen pans, a part of which were glazed, and a part unglazed. In the last place, all the pans were filled with soft water, which had been boiled on the same evening. On the night alluded to, ice appeared in the pans, when the temperature of the air, at the height of 54 feet, was, according to a naked thermometer, 37°. A dry earthen pan was placed among those which contained water, and the inside of its bottom was found to be as much colder than the air, as the water was in the other pans, before ice appeared in them. Moisture was attracted by this pan during the night, which was afterwards converted into a film of ice.

In the course of his experiments, Dr Wells observed, that water exposed early in the evening in the open air to the sky, lost a little weight during a clear night. This he imputed to evaporation taking place before the water had been cooled enough to condense the vapour of the atmosphere, and to the weight gained afterwards being insufficient to compensate the previous loss. He therefore, water to the influence of the sky, until it was cooled to 34°; of this he put two ounces into each of two china saucers, which had also been exposed to the air, and then placed the saucers upon the straw-bed. In the morning a thin cake of ice was formed in both saucers, one of which had gained 2.4, and the other 3 grains in weight. Dew was also copious in the night. At one time grass was 9.6, and the exposed part of the straw-bed 12.9, colder than the air.

Dr Wells regards the result of these experiments as a decided proof, that the cause of the formation of ice, in such circumstances, cannot be evaporation; but before coming to this conclusion, he ought to have shown, that, during the experiments, there was no evaporation from the surface of the ground, as well as from the water in the pans. For it is easy to conceive, that the evaporation from the extensive surface of the fibres of the grass, might be sufficiently great to cool the air in contact with them below the freezing point, and that this temperature might afterwards be communicated to the air immediately above the pans, either by conduction, or the actual transference of the cooled particles of air. Taking this view of the matter, we can explain the reason why ice was formed in the pans, though the water which they contained suffered no loss by evapo-
Evaporation, or even gained a small addition to its weight, as part of the moisture which evaporated from the surface of the ground might have been condensed over the pans. Dr Wells mentions, on the authority of Sir R. Barker and Mr Williams, both of whom witnessed the process in India, that, for the complete success of the experiment, it is necessary the air should be very still; and he adds, that "wind, which so greatly promotes evaporation, prevents the freezing altogether," without seeming to be aware, that this fact is still more irreconcilable with his own hypothesis, it being well known, that radiation is not affected by a transverse current of air. But, admitting the opinion, that evaporation is the cause of the reduction of temperature, a good reason may be assigned why an agitated state of the atmosphere, though it tends to increase the evaporation, may be unfavourable to the formation of ice; because the air in contact with the surface, and whose temperature is reduced by the evaporation, is in that case carried off, and mixed with the general mass, before it has time to communicate its temperature to the water in the pans. No reason can be given, on the theory of radiation, why the congelation succeeds best when the pans are placed in excavations; but, on the theory of evaporation, these excavations afford receptacles for the cooled air, which, having its temperature diminished, is increased in specific gravity, and thus settles in the lowest situations. The slightest agitation of the air would prevent this. Though we state these objections against the hypothesis of Dr Wells, we are not disposed to say, that radiation has no share in the effect, or, that the theory which ascribes the reduction of temperature entirely to evaporation, is altogether free from difficulties. Several experiments, performed with the utmost attention to accuracy, are still necessary for the full elucidation of the subject.

In some of the arts, particularly dyeing and calico-printing, it is necessary to produce a quick evaporation without exposure to the light of day. This is sometimes done by suspending the wet stuffs in buildings for the purpose, having a great number of perforations, so as to exclude the light, but allow a continual current of fresh air to circulate through them; at other times, the same thing is effected by exposing the stuffs in a stove, which has usually a fire, and long flues for diffusing the heat through the room. The stove is furnished with several openings at the top, to allow the escape of the air after it becomes charged with vapour.

The desiccation of other bodies must be carried on, as much as possible, without the agency of heat: thus the form, as well as the colour of delicate plants, upon which so much of their value in the preserved state depends, would be in a great measure destroyed by exposing them to the heat of a stove. It has therefore been proposed, to dry them in an exhausted receiver, by suspending them over a vessel containing sulphuric acid, the mirrute of lime, or any other substance which has a strong attraction for humidity, and allowing them to remain in that situation, until the whole of their moisture was evaporated. It has even been proposed, though with less probability of success, to dry gunpowder in the same manner. On the subject of evaporation, see Phil. Trans. Euclid. The Mathematician, was born at Alexandria in Egypt, about 300 years before Christ. We have no certain information as to the precise period, either of his birth or death; nor do we possess many particulars respecting his life. It would appear that he resided constantly in his native city, and devoted himself to the study of the mathematics, which he cultivated and taught with distinguished success. Among his scholars, he had the honour of reckoning Ptolemy Philadelphia, King of Egypt, of whom Proclus relates an anecdote, worthy of being preserved, not only as it shows the friendship and familiarity which Euclid enjoyed with his royal pupil, but as it is strikingly characteristic of an enthusiastic geomcter, and the only one on record which brings him, as it were, personally before us. Ptolemy, fatigued with the long and unremitting attention necessary to comprehend the demonstrations of certain propositions, one day inquired of his teacher whether he could not point out an easier method of investigation? "No, sire," replied the philosopher, ingenuously, "there is no royal road to geometry." The work by which Euclid is best known to us, is his Elements; a work which, to use the words of a learned critic, "has weathered the vicissitudes of opinion for two thousand years, and has been translated into all the languages, both ancient and modern, in which there is refinement enough for the expression of abstract truth." Various opinions, however, have been entertained with regard to the share which Euclid had in the composition of these Elements. While some maintain that he was the author of the whole, others assert that the demonstrations only are his, and others that he furnished the propositions alone. As in most disputes of this kind, none of the contending parties are perfectly correct. Independent of the undeniable fact, that some particular propositions were furnished by others, as the 47th of the first book, by Pythagoras, it must be obvious, from the state of the mathematical sciences at the period in which Euclid wrote, that he could not be the author of the whole. Long before his time, mathematicians had been engaged in attempting to solve the famous problems of the duplication of the cube, and the trisection of an angle, problems which they never could have attempted without the assistance of many propositions to be found in his Elements. On the other hand, it seems impossible to grant, what is universally allowed, that he was the first who arranged all the propositions then known into a system, without granting a great deal more. The mind that was capable of putting such a system together, even though the materials had been ready furnished, could hardly fail to discover some room for improvement, some defect to be supplied, or some weak link that required to be strengthened. Reasoning, then, from what we might naturally suppose to be the process of a mind accustomed to scientific investigation, we shall be led to conclude that Euclid must have been the author of no inconsiderable part of the Elements. This circumstance, however, is immaterial, and not at all necessary to entitle him to the appellation of the Father of Geometry. Even supposing every proposition in the Elements to have been known and demonstrated, it is

Eucalyptus. See Botany, p. 279.

Euclid.
must have been guided in his studies in a great measure by accident—interrupted at every step of his progress, and obliged to go out of his way for the purpose of investigating a proposition of which he was not at first aware, but which was necessary for the demonstration of a more important truth. The length of time thus necessary, in the most favourable circumstances, for acquiring a knowledge of the fundamental propositions, and the difficulty of bringing them, after they were known to bear on any particular point, as to be useful in the investigation of new truths, must have presented obstacles of no ordinary magnitude even to the most skilful geometer, and rendered the future progress of mathematical discovery both slow and uncertain. Every person who has studied geometry, or paid any attention to the nature of mathematical investigation, will be ready to admit the truth of these remarks, and to acknowledge the extent of the obligations which he owes to Euclid; nor have the admirers of that distinguished mathematician any reason to lament his being denied, in some instances, the merit of original invention, while it is admitted that, by the skilful arrangement of the discoveries of others, he has put into the hands of his successors an instrument which, at a comparatively trifling expense of time and labour, has enabled them to reach at least a little of what is most valuable in the field of mathematical discovery.

As a question has been started with regard to the author of the Elements, so the merit of the work has likewise been a subject of discussion. While some maintain that it is not only the most perfect system of elementary geometry, either of ancient or modern times, but as absolutely beyond the reach of improvement, except so far as to free it from the blunders of ignorant commentators; others complain that the demonstrations are unnecessarily long and prolix, frequently intricate and indirect, and ill adapted to the purposes of instruction. Perhaps in this dispute, too, both parties are wide of the truth. It must be acknowledged, on the one hand, that for "rigid accuracy" of demonstration, perspicuity of language, and beauty of arrangement, the Elements of Euclid stand unrivalled, and that modern writers have excelled in these qualities, exactly in proportion as they have approached the Greek geometer. It must also be admitted, however, that in the present state of the mathematical sciences, even these Elements are susceptible of improvement.

Though they are equally necessary as the foundation of all mathematical investigation in which magnitude is concerned, yet they do not bear the same proportion which they once did to the whole science. They still deserve, as much as ever, to be studied on their own account; but as the field to which they open a way has vastly increased, and still continues to increase, it has become a matter of no inconsiderable moment to abridge, as much as possible, the labour necessary to acquire a knowledge of the elementary truths which they contain. On this account we are disposed to regard some modern treatises of geometry, as possessing advantages unknown even to Euclid; not that they excel, or even equal him, in elegance and correctness of demonstration, but because they conduct the learner with greater facility to the exterior and more important objects of inquiry. With all these concessions, however, we are not prepared to admit an insinuation that has been sometimes thrown out, as if Euclid owed the continuance of his celebrity to an unreasonable and pertinacious adherence to a system, merely because it is ancient. To such prejudices has been ascribed, and we believe justly, the boulage in which the human mind was long held by the metaphysics of Aristotle. But to ascribe the reputation of Euclid to a similar cause, is to place him infinitely lower than he was ever destined to stand, and to assign to an authority over mankind, which it never possessed. Bigotry and superstition may retard or suppress a spirit of mathematical inquiry; but we cannot admit the possibility of such a gross perversion of the human intellect, as to suppose that any thing but intrinsic excellence could secure to an elementary system of geometry, the almost unanimous approbation of mathematicians for two thousand years.

The other work to which Euclid is in any degree indebted for his reputation with posterity, is his Book of Data. This treatise, like his Elements, had suffered much from the ignorance of commentators, as well as from the depredations of time; but, like the latter, revived with fresh vigour under the renovating hand of Dr Simson of Glasgow. It is still perhaps unnecessarily prolix, and not at all entitled to the estimation in which it was held by the ancients. At the same time it is certainly valuable, as containing the rudiments of this geometrical analysis.

Of Euclid's books on Porisms, nothing can be collected from ancient writers, except that he did treat of such propositions, and that they were regarded by the ancients, as forming a very important part of their analysis. They were restored, or rather discovered anew, by Dr Simson, and published after his death by the late Earl Stanhope. See Analysis, Porisms, &c.

Besides the subjects already mentioned, Euclid is known to have studied various other branches of the mathematics, particularly the conic sections, optics, and astronomy. See Conic Sections.

It would be impossible to enumerate all the editions through which the Elements have passed, and the commentaries that have been written upon them since the days of Proclus. Those of Commandini in 1572, and Gregory in 1703, deserve to be mentioned; but it seems to be universally admitted, that Dr Simson's of Glasgow is superior to every other.

Of those who have written on geometry, with the view of accommodating it to the present state of the mathematical sciences, Legendre, Lacroix, Mr Playfair, and Mr Leslie may be mentioned as the most successful. Mr West too, deserves to be noticed as the author of an elementary treatise of mathematics, which has not hitherto enjoyed the celebrity to which it is so justly entitled.

EVESHAM, VALE OF. See Gloucestershire and Warwickshire.

EVESHAM, is a borough and market town of England, in the county of Worcester, pleasantly situated on a rising ground upon the river Avon, over which there is a stone bridge of seven arches, and where there is a convenient harbour for barges. The streets are in-
eral wide and spacious, and the houses are well built of brick. There are three parish churches, viz. All Saints and St Lawrence in Evesham, and St Peter's in Bengworth; a free grammar school, a charity school, and an alms house. Although each of the churches has a tower, yet the bells are suspended in a handsome old Gothic tower about 100 feet high, and separate from any other building. This beautiful tower is 117 feet high, and 22 feet by 22, and is considered as the last monastic building erected in England.

There was formerly at Evesham a stately monastery, whose Abbot sat in the House of Peers. Its privileges were valued at £1183 annually, at the dissolution. It was founded in 790 by Prince Egwin, who retired here after the Pope had deprived him of the bishopric of Worcester. Of the few vestiges of it which now remain, the principal are the above tower, and a large elliptical arched gateway 17 feet long, ornamented with rich though mutilated images.

The following is the population of the borough according to the late returns for 1811:

Inhabited houses .................. 674
Families that occupy them ...... 714
Families employed in agriculture 313
Do. in trade and manufactures 339
Males ................................ 1871
Females .............................. 1697
Total population .................. 3068

An account of the battle of Evesham will be found in our article ENGLAND, vol. viii. p. 618. See Tindal's Evesham. (f)

EUGENE, FRANCIS, Prince of Savoy, was born in 1669, and was descended from Carignan, one of the three branches of the house of Savoy. His father was Eugene Maurice, Earl of Soissons, general of the Swiss and Grisons, and governor of Champagne in France; and his mother was Olympia Marcini, niece of Cardinal Mazarin, a woman of an intriguing disposition, and once the chief favourite of Louis XIV. He was at first intended for the service of the church, and in 1670 was committed to the tuition of a doctor of the Sorbonne. Here he gave great hopes of proficiency in polite literature; but was observed, even at that early age, to derive the greatest pleasure from the perusal of Curtius and Caesar; and soon indicated a strong predilection for the military profession. His father, however, having died before his son was ten years of age, and his mother having lost all her influence with the French monarch, who even banished her from his dominions, Eugene found his prospects of promotion in that country considerably diminished. He was still maintained by the king according to his rank; but was refused an abbey, because he was considered to be more addicted to pleasure than to piety; and a commission in the army, because he was of too delicate a constitution. He seems afterwards to have admitted, that Louis nevertheless had some regard for him, and would have at length provided him with a suitable employment in his service; but thinking at the time that his merits were slighted, and feeling himself involved in the disgrace of his mother, he quitted France in 1683, full of enmity against its sovereign, and vowing that he would never re-enter his territories except with arms in his hands. In company with his brother Philip, who had received from the Emperor of Germany the command of a regiment of horse, he arrived at Vienna at the moment when it was closely besieged by the Turkish army. He immediately joined the Duke of Lorraine as a volunteer; and, having greatly signalized himself both in the defeat and pursuit of the enemy, he was appointed, in the course of a few months, to a colonelcy of dragoons. In 1684, he was present at the sieges of Neuhofen and Buda, where he gave such unequivocal proofs of intrepidity and intelligence, that, on his return to Vienna in 1686, the prince of Baden presented him to the emperor with these prophetic words: "Sire, here is a young Savoyard, who will some time or other be the greatest captain of the age." Thus he rose daily in favour at the court of Vienna; and so great was the rapidity of his military advancement, that he was a major-general at the age of 21, and a lieutenant-general at 25. In 1689, when the French monarch declared war against the emperor, and it became necessary to form a coalition against his ambitious schemes, Prince Eugene was sent from Vienna to negotiate an alliance with his cousin, Victor Amadeus, duke of Savoy. That selfish and aspiring prince, who loved neither Louis nor Leopold, and who was ready to betray both as his interests required, was secured on the side of the Imperialists by the title of Governorissino, from Austria,—a subsidy of 20,000 crowns per month from England, a similar allowance from Holland, and the promise of four millions more to defray the expenses of the war. Eugene was sent with a reinforcement of German troops to keep him steady to his engagements, as well as to co-operate with him in the field; and, during the seven campaigns, which they carried on with various success, he found occasion for all his talents to watch against the bad faith of the duke, to retrieve the errors of his bad generalship, and to make head against the able tactics of the French commander Catinat. In spite of all these disadvantages, he succeeded in penetrating into France, and had opened a free passage to Lyons, when Amadeus was seized with the small-pox, and Eugene was obliged to withdraw the army to Turin. In reward of his exploits, he received this year the order of the golden fleece; and was created a field-marshal exactly ten years after his entrance into the service. He was greatly thwarted by his unmanageable ally, during the remainder of the war; and at last, in spite of all his vigilance, the duke concluded, in 1696, a separate treaty with the French, whom he soon afterwards joined against the emperor. The king of France, thinking that Eugene was discontented with the court of Vienna, or that they were discontented with him, made a proposal that he should enter his service. He is said to have offered him his father's government of Champagne, an annual pension of 2000 pistoles, and the rank of a marshal of France; but, so strong was the prince's antipathy to Louis, that he rejected the offer with the greatest disdain. "I received gaily," he says in his Memoirs, "the person who brought the proposal, and he did not surely dare to deliver my answer exactly as I spoke it." Notwithstanding the unfavourable result of affairs in Italy, the emperor saw that he was free from all ground of reproach, and sufficiently testified his approbation, by giving him the command of the army in Hungary. In 1697, he took the field against the Turks, who were commanded by the Grand Seignor in person; and inflicted upon them the severest defeat which they had sustained in the whole course of the war. While marching to attack them at Zenta, on the river Tesse, he received an order from Vienna, not to fight a battle in any circumstances; but, having advanced too far to retreat with honour or safety, he hastened to the assault, forced the entrenchments of the Vizier's camp, defeated his army with great slaughter, and made himself, master of an immense booty, to the amount of several millions stern-
ling. Of the enemy, 20,000 were killed in the field, 10,000 drowned in the river, and 4,000 taken prisoners; while the victorious Imperialists did not lose one thousand men. But his enemies at Vienna having gained the ascendancy, he was received by the Emperor with the greatest coldness, commanded to deliver up his sword, charged with disobedience of orders, and arrested for trial before a council of war. Upon the report of these proceedings, the populace assembled around his house; and the citizens offered to form a guard about his person, to prevent his being removed for examination. The emperor, either from fear or from conviction, restored his sword, and requested him to resume the command in Hungary. His answer was, as he has recorded it with his own pen, "I will do it upon condition of having carte blanche, and of not being exposed in future to the malice of generals and ministers."

"The poor emperor," he adds, "durst not give me this full power publicly; but he gave it me in private under his own signature, with which I was quite satisfied." The war with the Turks was terminated in another campaign; and now for the first time he commenced his military career. He was left at leisure to cultivate the arts of peace. He employed himself in forming a select library, collecting paintings, building palaces, planning gardens, and hearing music; in preference, as he says, to "the talk of idlers." During this interval of peace, he enjoyed the society of the celebrated French General Villars, who was ambassador at Vienna; and with whom he maintained, during the remainder of his life, a most cordial friendship, which was not interrupted even in the midst of hostilities.

When the war of the Spanish succession broke out in 1701, Prince Eugene was appointed to the command of the Austrian army in Italy, which consisted of thirty thousand veteran troops. His cousin, the Duke of Savoy, was now in alliance with the French, and frequently commanded against him in person. The army with which he had to contend, was uniformly superior in number; and was successively conducted by Catiniat, Villeroy, and Vendome. Against the first and the last, all his activity was unavailing; but he gained several temporary successes when Villeroy had the command, and even made him his prisoner, in a bold though unsuccessful attempt to surprise Cremona. After two years absence, he returned to Vienna in 1703, to secure for his army the extraordinary supplies of money and men, and being there appointed to the presidency of the military council, he rendered great services to the Austrian empire in that office, by effecting an accommodation with the Hungarian insurgents, and detaching the Duke of Savoy from his connection with France. He was chiefly instrumental, also, in concerting with the Duke of Marlborough the plan of the campaign of 1704, in which he bore so distinguished a part, and which so completely relieved the hereditary dominions of Austria from the formidable danger which threatened them on the Danube: (See Blenheim.) In 1705, he was sent into Italy with an army of 28,000 Austrians, in aid of his cousin the Duke of Savoy, who was now heartily exerting himself in opposition to France. During the first campaign, while Vendome commanded the French, he made very little progress in freeing Savoy from the enemy; but, in the following year, when Marsin and La Feuillade were placed at the head of the hostile army, he gained with an inferior force, and after an obstinate contest, the famous battle of Turin, which was followed by the deliverance of Italy, and the invasion of France. Returning to Vienna, he was dispatched in 1708, as a negotiator to consolidate the coalition; and then hastened with his army to form a junction with Marlborough, who was encamped at Asch in the vicinity of Brussels. Here he had an interview with his mother, after an absence of twenty-five years; and though his troops were not come up, he concurred with the English general in advising an attack of the French army, and in gaining the decisive battle of Oudenarde. Having ravaged Artois and Picardy, they undertook the siege of Lisle, which, after being obstinately defended by Marshal Boufflers nearly six months, surrendered to the allied arms. While Prince Eugene was actively employed in superintending the siege of the town, his enemies, either at Vienna or at Paris, are reported to have made an attempt upon his life by poison. A letter was put into his hands, which contained only a piece of greased paper, which he threw away; but, being picked up and given to a dog, or rather, as it was said, being tied about the animal's neck, he expired in twenty-four hours, with all the symptoms of having been poisoned. The prince himself remarks upon this occurrence: "I do not believe that there have been any mistakes in the supposed cause of the animal's death; and that the paper probably contained some piece of information, which might have been rendered legible by the fire, or some of the usual applications, in secret writing. In 1709, he found himself, together with Marlborough, at the head of 100,000 men in the Low Countries, opposed to an army of equal force under Villars, who acted prudently on the defensive, and made the confederates pay dear for their successes, particularly in the bloody battle of Malplaquet. It was chiefly by the advice of Eugene, that the allied forces ventured upon that daring assault; and he seems to have been fully aware how much depended upon the result. He had received a wound behind the ear, when forcing an entrenchment; and, when urged by his friends to have it dressed, he instantly replied, "If I am beaten, it will not be worth while; and if the French are, I shall have time enough."

"What better," he adds, "could I have done than to have perished, after the serious responsibility which I had taken upon myself?" In 1711, the Emperor Joseph I. died of the small-pox; and Eugene, by his skilful manoeuvres, had considerable influence in securing the election of his brother Charles, competitor for Spain. This circumstance, by increasing the power of Austria, rendered the other armies powerless, except in the coalition against France; and the prince was dispatched to London, in order to retard the progress of a peace. Here he was received in a manner suitable to his merits and reputation, but was unable to accomplish the object of his mission. Though Marlborough was now in disgrace, and it might have been politic to have shunned his intercourse, Eugene met his old companion in arms with undisguised emotion, and passed the greater part of his time in his company. For this, he says, the populace applauded him the more, and the more honest individuals of the opposite party did not esteem him the less. The allies, though deprived of the assistance of Britain, had so much confidence in the talents of Eugene, that they still continued the war in 1713; and, though now obliged to act solely on the defensive, he greatly signalized himself by his active vigilance, and at one time, by a bold advance into Champagne, he occasioned no small alarm to the court of Versailles. At length, all parties being worn out with perpetual war, Eugene was appointed to negotiate with Villars at Rastadt; and, in the course of the year 1714, concluded a general peace.
EUGENE.

225

between the empire and France. Upon his return to Vienna, he was received, both by the court and the city, with the most enthusiastic testimonials of approbation, and immediately applied himself to improve the state of the public finances. But his respite from the fatigues of war was very short. In 1710, hostilities commenced against the Turks, and he was appointed to the command of the army in Hungary. Attacking the enemy in the land of the Magyars, and via the important fortress of Temeswar, which the Turks had held 164 years, he opened the campaign of 1717 with the siege of Belgrade, where he was attended by a number of princes and young men of rank, who were eager to exalt their reputation, and to improve their military skill by serving under him as volunteers. A large army arrived on the 1st of August to relieve the place, when his own was weakened by a fever, and himself suffering under the same disease. But recovering from his illness about the middle of the month, he resolved, as his only hope, to attack them during the night, and after a desperate resistance, drove them from the heights, gained a decisive victory, and received on the same day the capitulation of Belgrade. A peace was concluded in the following year, and he was appointed by the emperor his vice-general in Italy, with a salary of 150,000 florins. During a long repose of nearly fifteen years, he applied himself to the study of the arts—the arrangement of his books, maps, and plans—the embellishment of his palace and his gardens—and particularly to the perusal of the best authors. Nor was he idle in his public capacity, but exerted himself to regulate the internal state of the empire, especially to the improvement of its commerce. In 1733, when it was proposed to resist, by force of arms, the intention of the French court to replace Stanislaus on the throne of Poland, he strongly dissuaded the emperor from a war in which he foresaw so little support, and so formidable an enemy; but his counsel was overruled, and he accepted the command of the army at the age of seventy. He was received by the soldiers at Phillippsburg with repeated cries of "Long live our father!" while thousands of hats waved in the air. "My old soldiers of Hungary, Italy, Flanders, and Bavaria, ran to take hold of his horse's neck, and they surrounded me; they fastened on my horse, and even pulled me down with the weight of their caresses! This was assuredly the most delightful moment of my life." Though greatly inferior in numbers, he prevented the Duke of Berwick from penetrating into the heart of the country, and baffled the talents of D'Asfeld by skillful marches, but in the following campaign he finished his military career by operations of a more active nature, taking Trarbach, and delivering the electorate of Treves. Having always advised a speedy termination of so profitable a war, he was not dissatisfied at being recalled to Vienna, to assist at the negotiations for peace; and though he took leave of his army with tears, he continued, during the remainder of his life, to be the advocate of pacific counsels. Though naturally fond of military renown, and the most ardent of combatants in early life, his cooler judgment and long experience led him to form a more enlightened opinion of the evils of war. "The thirst of renown sometimes insinuates itself into the councils under the hypocritical garb of national honour. It dwells on imaginary insults—it suggests harsh and abusive language—and people go on from one thing to another, till they put an end to the lives of half a million of men. A military man becomes so sick of bloody scenes in war, that in peace he is averse to recommence them. I wish, that the first minister, who is called to decide on peace and war, had only seen actual service. What pains would he not take to seek, in mediation and compromise, the means of avoiding the effusion of so much blood?"

He spent the remaining year of his life in complete retirement, in the conversation of his friends, in the society of young persons, whose company he preferred, and in a becoming attention to the offices of religion. "I have been happy in this life, and hope to be happy in the next. I have scarcely had time to commit transgression; but I have set a bad example, without thinking, by neglecting the exercises of religion, though a sincere believer in and well acquainted with its doctrines. I have led a soldier's life of indifference, and have acted the part of a philosopher; but my death I wish to be that of a Christian. I never liked boasters either in war or religion; and it is probably from being seen on one side the ridiculous impiety of the French, and on the other the bigotry of the Spaniards, that I have observed a medium between the two. In former days I had so often seen death before me, that I had become familiar with it; but this is not now the case. I then sought it; now I wait for it; but I await it with tranquillity, and look on the past as a pleasing dream. I am fond of the eloquence of the pulpit: When Bourdaloue has made me fear every thing, Massillon makes me hope every thing; Bossuet astonishes and Fenelon affects me. I have forgotten the epigrams of Rousseau, and even his ode to me; but I often read his Psalms and his Canticles." This illustrious commander, who had received thirteen wounds, and who, in almost every one of his numerous battles, had made many hair-breadth escapes, died at length tranquilly at Vienna, on the 10th of April 1736, in the 73rd year of his age. He was found dead in his bed, after having retired in good health from entertaining company at supper; and was supposed to have been suffocated by an immediate delusion of rheum, to which he was subject. Little remains to be remarked upon his character, in addition to what may be suggested by the sketch of his history, and the extracts from his private memoirs, which we have presented to our readers. In his military tactics he is considered as having frequently bordered upon rashness, and having been generally too lavish of human blood. He was distinguished for personal courage, and for his coolness in the midst of dangers; and he mentions two circumstances, from which he derived the greatest advantages, viz. always reconnoitring if possible in person, and writing with a pencil in the memorandum-book of his aide-de-camp, every order which he gave him to carry. He has been greatly commended for his generous disposition; for the case with which he descended to an equality with those who conversed with him; for his unaffected modesty, which prevented him from assuming any thing over others, and which rendered him unable to bear, with any tolerable grace, the just acknowledgments which were paid to his merits. See Biographical Dictionary; Life of Eugene; Modern. Univ. Hist. vol. xxv. p. 101, and vol. xxx. p. 396; Memoirs of Prince Eugene of Savoy, written by himself.

EUGENIA. See BOTANY, p. 228.
EUHARMONIC ORGAN, is a very improved musi-

2^
Eupharmonic organ, the first that ever has been capable of producing perfect harmony, or music wherein none of the harmonies are tempered or imperfect, in the widest range of modulation, the invention of the Rev. Henry Liston, minister of Ecclesmachan in Scotland, for which he took out a patent in 1810; (see the Phil. Mag. vol. xxxvii. p. 328; vol. xxxviii. p. 401; and the Monthly Mag. vol. xxxvi. p. 217). The first of these instruments was perfected in Edinburgh, and had a separate pipe for each of the numerous sounds wanted. The 12 finger-keys in common use were made to act always on as many contiguous notes of the scale, by means of six pedals, discharging two sharps at a time, and bringing on as many flats, or vice versa, in the order of modulation; single pedals or foot movements being a most important improvement on the separate hand-slides in the harpsichords constructed on Dr Smith's plan, and in the organ of the Foundling Hospital, London; and it is somewhat remarkable, that the same system and construction of pedals occurred about the same time to Mr David Leeschman in London, who afterwards took out a patent for applying the same to his improved organ, and piano-fortes, for tempered systems. Besides the a and b pedals above described, Mr Liston had others for occasionally shifting the finger-key movements from one pipe to another, higher or lower than it, by the interval of a major comma.

In order to lessen the bulk and expense of this first construction of his organ, Mr Liston afterwards contrived a mode of temporarily lowering the sound of a pipe, either one or two commas, and restoring it again at pleasure, by means of a shaked, brought and held near to it, but not touching its orifice; and for this contrivance for diminishing the number of pipes, and for some improvements in the bellows, was Mr Liston's patent obtained.

After exhibiting this improved organ during a season in London, to the most eminent of the musical professors and amateurs, Mr Liston published his Essay on Perfect Intonation, a handsomely printed quarto work of 148 pages, besides 40 quarto pages of closely printed music, separately done up, to accompany it. This important work, forming a new era in the theory of music, and its practice on keyed instruments, is preceded by the most handsome and voluntary testimonials of four eminent London professors, who had performed on and heard the eupharmonic organ. The first part of this work treats of the perfect scale, temperament, and the principles and construction of the eupharmonic organ; the second part treats of musical chords, and their progressions, modulations, intervals, and their combinations in chords, modulation within the key, and passing into the subordinate keys, &c.; and, lastly, notes illustrative of the text. The engraved examples contain full and very explicit instructions for learning the use of the eupharmonic organ, in every key and kind of modulation, and eupharmonic changes; and the selection of pieces of music, from many of the best masters, which follow, being all, like the elementary examples that precede them, exactly marked wherever the different pedals are to be pressed by the foot or released, during performance, in order to produce the exact perfect chords that the several composers intended; and such, indeed, as the amateurs of music are daily in the habits of hearing, in the performances of correct singers, either alone, or accompanied only by separate perfect instruments for single parts, like the violin, violincello, sliding trumpet, &c. (whereon the exact pitch of the notes can be instantly varied at pleasure), or performances wholly by such perfect instruments, for a band of good performers, whose refined and delightful harmony had never, in any considerable degree, been produced, by a single performer, before the exhibition of the patent organ of which we are speaking.

The eupharmonic organ seems an essentially requisite instrument to the singing master, by which, in the shortest and most perfect manner, a habit of correct intonation in the various keys, and harmonizing with their fellow performers in every case, might be acquired, and fixed in his pupils; and not only so, but practising often with such an instrument would give almost equal precision to the performance of those discords that occur, and so essentially contribute to the beauties of most compositions, when correctly given, as they are on this organ, but which, it is presumed by the writer, very rarely happens even with our best performers of single parts in concert, for want of any audible phenomenon, like the beats of imperfect concords, to exactly fix the idea of perfection in discord while learning to perform, or in practising, as the cessation of beats do for the concords; and, accordingly, he was most forcibly struck on first hearing Mr Liston's organ, with the perfectly new and peculiar character of several of the discords, when heard alone, but more especially when combined in certain chords; the pleasing effect, for instance, of the II, 7, IX (and 7'), and what is more surprising, of the IX VI, (and IX II and IV), when combined, as Mr Liston describes in pages 57, 69, 73 and 99 of his Essay, and wherein he mentions also at page 56 (and 99) and 71; the disagreeable effect of 7 (and 5, II and IV) in the dominant seventh, and of 2 in the chord of greater seventh, &c.

To teachers and students of the violin, violincello, &c., the eupharmonic organ would prove a valuable guide and test for stopping in tune, particularly with the discords. And, above all, to the theoretic musician and composer this instrument cannot fail of proving at all times useful, for trying the precise effect of every combination of harmony that may suggest itself, and for beneficially extending the bounds of this difficult part of the science. (c)

EVIAN, a town of Switzerland, situated on the south side of the lake of Geneva, about eight or nine leagues from Geneva. It contains two parishes and two convents. About half a league from the town, on the side of Thonon, at the foot of the hill of Amphion, there is a spring of mineral water, which is much frequented in summer. Thirty-six ounces of it contains a grain of iron, two grains of selenite, and 6 grains of lime. The banks of the lake of Geneva are here remarkably fine. Not very long ago, carriages could not go any farther east than Evian. In order to reach Meillerie and St Gingolp, it was necessary to follow a very dangerous footpath along the margin of the lake, and even travellers on horseback, were often obliged to dismount. Since the year 1805, however, a great military road, communicating with the Valais and with the Simplon, has been cut through the rocks, commanding, all the way to St Maurice, a charming view of the Lake of Geneva and of its northern banks. Population of the town 1502. (m)

EVIDENCE. See Logic.

EVIL, Kino's, is the name formerly given to scrofula, in consequence of its being supposed that the kings of England and France possessed the power of curing this disease by the touch. The English and
French have each contended that this power was first exercised by their respective monarchs; the French asserting that St Louis was first endowed with it, and the English that it was possessed by Edward the 1

In the reign of Charles II, the practice seems to have reached its greatest height; and such were the crowds that flocked to the royal physician, that he is said to have touched more than six thousand persons in one year, after his restoration. The demands upon the king's time were so great, that he found it necessary to have the patients examined by his surgeons, for the purpose of determining from their certificates if they were proper objects of compassion. They then received tickets of admission to the royal presence, and were touched by the king on one of the days of healing, either at Whittingham or Windsor. After touching those that were brought to him, the king put about each of their necks a white ribbon, with an angel of gold upon it.

During five years, from 1660 to 1664 inclusive, 23,601 persons were touched by Charles II. and from May 1667 to May 1669, the number amounted to 68,506 making in all 92,107.

See Wiseman's Chirurgical Treatises, Book IV. chap. 1. Browne's Adeno-Chiradodia, or an "anatomical-chirurgical treatise of glands and struma, or king's evil swellings," together with the royal gift of healing or cure thereof, by contact or imposition of hands, performed for above 640 years by our kings of England, continued with their admirable effects and miraculous events, and concluded with many wonderful examples of cures by their sacred touch." See also the Edinburgh Medical and Surgical Journal, Vol. III. p. 183. (w.) EVIL. See THEOLOGY.

EULER'S LOGARITHMS, for musical calculations, are a series of artificial numbers invented by this author, for expressing musical intervals in their relations decimally to the octave, as unity, forming a set of BINARY LOGARITHMS, which see. The writer has known a learned student of Euler's famous work on music, wherein these logarithms are used, stopped for want of being able to deduce common logarithms and lengths of strings from M. Euler's numbers affixed to the intervals; not considering, that one constant ratio must obtain between the corresponding logarithms in any two tables of different kinds, and another constant ratio between their reciprocals respectively.

In the present case, the reciprocal logs. (or those which increase with the numbers or intervals) of Euler's, and the common log. of the octave, (or ratio \( \sqrt[n]{2} \)) are \( 1 \) and \( .30103 \), respectively. We have only, therefore, to multiply any of Euler's log. by \( .30103 \), to obtain nearly its reciprocal common log. If, for example, the medium semitone, the first of Euler's notes above F, were given, we have \( .97641 \times .30103 = .02931233 \), whose recip. \( .9764767 \) is the common log. near enough for most experimental purposes; and the number answering to this last is .93815, the length of string to the unison 1.

In like manner, if Farey's artificial commas were wanted from Euler's logs, since both of these are of the nature of reciprocal logs, the octave being expressed by 612 and 1 in them respectively, we have only to multiply Euler's logs. by 612, to obtain nearly their artificial commas. The last example will stand thus: \( .97641 \times 612 = 47.01068 \), or 47, as in the schisma column (2) of Plate XXX. Vol. II.; and it may be remarked hereon, that whenever the product approaches a whole number, either above or below it, that such whole number is, in general, the proper number of artificial commas sought.

EULER'S SCALE of musical intervals. It is probable, we think, that M. Euler made the first, though an unsuccessful attempt, at the grand harmonic improvement, (which Mr Liston has lately effected, by his scale of perfect harmony, and his EUHARMONIC Organ, which see), by endeavouring, on a very limited scale, to avoid tempered or imperfect concords, by means of more notes introduced in the octave than the 12 in common use. M. Euler extended these 24, eight of which new notes were only a major comma higher than his notes C\( ^{\text{f}} \), D\( ^{\text{f}} \), E, F\( ^{\text{f}} \), G\( ^{\text{a}} \), A, B\( ^{\text{g}} \), and B; and four others of them a minor comma lower than his notes D, F, G, and C; at the same time, that three notes of his original scale differ from Liston's, viz. C\( ^{\text{f}} \), E\( ^{\text{f}} \), and B\( ^{\text{g}} \), in having the ratios \( 2^{4} 0^{4} \) 128, \( 2^{5} 7^{5} \) 225, \( 13^{5} 7^{5} \) 161, which are Liston's notes respectively.

In order to facilitate the labours of those, who, like the gentleman alluded to in the last article, may be desirous of trying, either by calculation or experiment, the effect and extent of this scale in producing perfect harmonies, we have been at the trouble of reducing M. Euler's vingquatreave scale, from the octave F to f, in which he has published it, to that of C to c, in which all musical scales are given in our work; and we have added in the columns of the following Table, the lengths of strings, and number of artificial commas, answering to each of Euler's notes; and in the last column but one, we have set down the notes on Liston's organ, (see the Phil. Mag. vol. xxxiv. p. 419, or the Monthly Mag. vol. xxxvi. p. 217,) wherein the several chords in this system might be tried, and whence these notes might be transferred to a new instrument, if it were thought worth any one's while to make such a one, having a pedal for bringing on the eight acute notes, and another for supplying the four that are minor comma flats, in the place of their respective original notes, as often as they are wanted in performance, in this scale proposed by M. Euler. The last column shows the numerical value of the notes, major and minor, above C.
The want of minor consonances above C, are very obvious in the above system, which most probably M. Euler never tried any more than the equal temperament, although his name has been often enrolled among the very numerous theoretic recommenders of the isometric system. (q)

**Euler, Leonard**, one of the most distinguished mathematicians of the 18th century, was the son of Paul Euler, and Margaret Brucker, and was born at Basle on the 15th of April 1707.

His father, who had been instructed in mathematics by the celebrated James Bernoulli, became pastor of the village of Kiechen, near Basle, in the year 1708; and as soon as his son had arrived at the proper age, he instilled into him a fondness for mathematical learning, although he had destined him for the study of theology. He was afterwards sent to the university of Basle, where he was found worthy to receive lessons from John Bernoulli, who was at that time regarded as the first mathematician in Europe. The assiduity and amiable disposition of Euler, soon gained him the particular esteem of that great master, and the friendship of his two sons Daniel and Nicolaus Bernoulli, who had already become the disciples and the rivals of their father. John Bernoulli even condescended to give him once every week a particular lesson, for the purpose of explaining the difficulties which he encountered in the course of his studies. Euler had not the good fortune to enjoy long this inestimable advantage. In 1728, he received the degree of Master of Arts; and on this occasion, he obtained great applause by the Latin discourse which he delivered, containing a comparison between the Newtonian and the Cartesian philosophy. At the request of his father, he now began the study of theology; but his attachment to the mathematics was so strong, that his father at last consented to allow him to follow the bent of his own genius.

Nicolas and Daniel Bernoulli having accepted in 1725 of the invitation of Catherine I. to become a member of the Academy of Sciences at St Petersburg, promised at their departure to employ their influence, to procure for Euler an appointment in that city. In the following year they wrote to him, that they had a situation in view for him, and strongly advised him to apply his mathematical knowledge to physiology. Euler immediately attended the lectures of the most eminent medical professors of Basle, and made rapid progress in the study of medicine. His attention, however, was still directed to his favourite pursuits, and he found leisure to compose a dissertation on the Nature and Propagation of Sound, and another on the Motion of Ships, which was written for the prize proposed by the Academy of Sciences in 1727. As this subject was actually suggested by several members of the Academy, with the view of bringing into notice the talents of M. Bouguer, who had paid particular attention to this subject, and who was then professor of hydrography in the sea-port town of Croisic, it was not likely that Euler, who was destitute of all practical knowledge of the subject, should have succeeded in the competition. Bouguer, of course, carried off the first prize; but Euler obtained what is called the accessit, or second prize, an honour of no trivial magnitude, when we consider that he was then only 20 years of age. About this time, Euler was a candidate for the vacant professorship of natural philosophy in the university of Basle; but he had not the good fortune to be elected.

Daniel and Nicolas Bernoulli used all their influence to procure an appointment for their young friend; and having at last succeeded, they requested him to repair immediately to St Petersburg. Euler lost no time in obeying this welcome summons; but, after he had begun his journey, he had the mortification to learn that Nicolas Bernoulli had fallen a victim to the severity of the climate; and the very day upon which he entered the Russian territory, was that of the death of the Empress Catherine I.; an event which at first threatened the dissolution of the Academy, of which she had laid the foundation. Having reached St Petersburg at this unfortunate period, Euler resolved to enter into the Russian navy, and had actually received the promise of a lieutenancy and rapid promotion from Admiral Sievers; but fortunately for geometry, a change took place in the aspect of public affairs in 1730, and Euler obtained the situation of Professor of Natural Philosophy. In 1733 he succeeded Daniel Bernoulli, when that illustrious mathematician retired into the country; and in the same year he married Mademoiselle Grell, a Swiss lady, and the daughter of a painter, whom Peter the Great had carried into Russia upon his return from his first tour. In 1735, a very intricate problem having been proposed by the Academy of St Petersburg, Euler completed the solution of it in three days; but the exertion of his mind had been so violent, that it threw him into a fever, which endangered his life, and deprived him of the use of one of his eyes. In 1738, the Academy of Sciences at Paris crowned his memoir, entitled, *Sur la Nature et les Proprietes du feu*, and in 1740, he divided with Daniel Bernoulli, and our countryman Colin Maclaurin, the prize given by the same Academy, for the best dissertation on the flux and reflux of the sea. Daniel Bernoulli had treated the subject with a sagacity and method which characterized all his labours. The dissertation of Maclaurin contained his celebrated theorem on the equilibrium of ellipsoidal spheroids; and that of Euler contained an improvement on the integral calculus, which seemed to resolve the fundamental equation of almost all the great problems on the motions of the heavenly bodies.
In consequence of an invitation from the King of Prussia, through his minister the Count de Marlefeld, Euler quitted St Petersburg, and went to Berlin in the month of June 1741. Upon his arrival, he was honoured with a letter from the King of Prussia, written from his camp of Reichenbach, and he was soon after presented to the queen-mother, a princess who took great pleasure in the conversation of illustrious men. She treated Euler with the utmost familiarity; but never being able to draw him into any conversation but that of monosyllables, she one day asked him why he did not wish to speak to her? "Madam," replied Euler, "it is because I have just come from a country where every person who speaks is hanged."

The memoirs and works with which Euler enriched mathematics and physics are so extremely numerous, that it would occupy many of our pages to give even the briefest account of them. We shall, therefore, content ourselves with referring the reader to the articles Achromatic Telescopes, Algebra, Arithmetic of Sines, Astronomy, Fluxions, Mechanics, and, in short, to almost every article in mathematics and physics which occurs in our work. A full account of Euler's discoveries and investigations will be found in these articles, and it would only be a waste of time to resume these subjects under the present head. In many of his physical memoirs, Euler has been justly reproached for having applied the calculus to the most unfounded physical hypotheses, or to metaphysical principles, which had not been sufficiently examined; and on this account many of his memoirs have no value whatever, except in so far as they exhibit fine specimens of the resources of analysis. His Disquisitions on Wind Mills, on Achromatic Telescopes, on Naval Architecture, and on Gunnery, are among the number of those which are liable to this criticism.

When Euler was at Berlin, the Princess of Anhalt Dessau, the niece of the King of Prussia, was desirous to receive from him some instruction in the different branches of natural philosophy; and for her use he drew up a work, entitled, Lettres a une Princesse d'Allemagne, which was translated into English by the late Dr Henry Hunter, and which, with the exception of the metaphysical part, has always been much esteemed particularly for the singular perspicuity with which its author has explained some of the most profound truths in physics. The King of Prussia often employed Euler in calculations relative to the mint, and other objects of finance, in the conducting of the waters of San Souci, and in the examination of canals, and other public works.

In 1744, Euler was appointed director of the mathematical class of the academy, and in the same year he obtained the prize offered by the Academy of Sciences of Paris, for the best work on the theory of magnetism.

About this time Robin's Treatise on Gunnery had appeared in England, and though our countrymen had treated Euler with great severity, this act of injustice did not prevent him from recommending it to the king of Prussia, as the best book on the subject. He even translated it, and in the additions which he made, he gave a complete theory of the motion of projectiles. Mr. Turgot ordered this work to be translated into French, and introduced into the schools of artillery; and about the same time there appeared a splendid edition of it in England.

In 1746, he published his new Theory of Light and Colours, and in 1759, his memoir Sur les effets du Teulot et du Tangage, gained the prize offered by the French Academy of Sciences.

In 1750, Euler went to Frankfort to receive his mother, who was then a widow, and to conduct her to Berlin, where she remained till the time of her death in 1761; having enjoyed for 11 years the assiduous attentions of a favourite son, and the high pleasure of seeing him universally esteemed and admired.

When Euler remained at Berlin, he formed an intimate acquaintance with M. De Maupertuis, the learned President of the Prussian Academy of Sciences, and he defended Maupertuis's celebrated and favourite principle of the least action, by resolving by means of it some of the most difficult problems in mechanics. In the dispute into which he was thus led with Koenig, who had attacked Maupertuis in 1751, he lost for a while his usual serenity, and became one of the enemies of that unfortunate individual.

Although the number of foreign associates in the French Academy of Sciences was limited to eight, yet Euler was appointed to the ninth place in 1755, on the condition that no appointment should take place at the first vacancy.

In the year 1760, the Russian army under General Tottleben penetrated into the Marche of Brandenburg, and pillaged a farm which Euler possessed near Charlottenburg. As soon as the Russian general was informed of the event, he immediately repaired the loss by a very large sum; and upon giving notice of the circumstance to the Empress Elizabeth, she added to this indemnity a present of four thousand florins. This act of generosity, no doubt, had a powerful effect in attaching Euler to the Russian government, which, in spite of his absence, had always paid him the pension which it granted him in 1742. Having received an invitation from the Empress Catherine, he obtained permission from the King of Prussia to return to St Petersburg to spend the remainder of his days; but his eldest son was not allowed to accompany him. When Euler was on the eve of his departure, Prince Czartorisky invited him, in the name of the king of Poland, to take the road of Warsaw, where, loaded with kindness, he spent 10 days with Stanislaus, who afterwards honoured him with his correspondence.

Shortly after his arrival in St Petersburg, on the 17th July 1766, he lost the sight of one of his eyes, having been for a considerable time obliged to perform his calculations with large characters, traced with chalk upon a slate. His pupils and his children copied his calculations, and wrote all his memoirs while Euler dictated to them. To one of his servants, who was quite ignorant of mathematical knowledge, he dictated his Elements of Algebra, a work of very great merit, which has been translated into the English and many other languages. Euler now acquired the rare faculty of carrying on in his mind the most complicated analytical and arithmetical calculations; and M. d'Alembert, when he saw him at Berlin, was astonished at some examples of this kind which occurred in their conversation. With the design of instructing his grandchildren in the extraction of roots, he formed a table of the six first powers of all numbers, from 1 to 100, and he recollected them with the utmost accuracy. Two of his pupils having computed to the 17th term, a complicated converging series, their results differed one unit in the fiftieth cypher; and an appeal being made to Euler, he went over the calculation in his mind, and his decision was found correct.

His principal amusement, after he lost his sight, was to make artificial loadstones, and to give lessons on mathematics to one of his grand-children, who seemed to evince a taste for the science.

In 1771, a dreadful fire broke out in St Petersburg,
and reached the house of Euler. M. Grimm, a native of Basel, having learned the danger in which his illustrious countrymen was placed, threw himself among the flames, and, reaching Euler's apartment, brought him off on his shoulders, at the risk of his life. His library, however, and his furniture, were consumed, but by the activity of Count Orloff, his MSS. were saved.

Having revised the lunar theory with the aid of his son, and of Kraft and Lexell, he constructed a set of new lunar tables, which appeared in 1772. These tables were, at the suggestion of Turgot, rewarded by the Board of Longitude in France; and when the more perfect tables of Mayer obtained the great premium of three thousand pounds offered by the British Parliament, the sum of three hundred pounds was given to Euler for having furnished the theorems made use of by Mayer in his theory.

In the year 1773, Euler published, at St Petersburg, his great work on the construction and management of vessels. A new edition soon afterwards appeared at Paris, and at the desire of the French king, it was introduced into the schools of Marine, and a reward of 1000 rubles transmitted to the author, accompanied by a handsome letter from the celebrated Turgot. About the same time an Italian, an English, and a Russian translation of it appeared, and the Russian government presented Euler with a gift of 2000 rubles.

Three of Euler's memoirs on the Inequalities in the motions of the Planets, were crowned by the French Academy of Sciences, and he also gained the prizes of 1770 and 1772, by his perfection of the lunar theory.

Having lost his first wife, by whom he had thirteen children, eight of whom died in early life, he was married a second time in 1776, to Mademoiselle Geell, the aunt of his first wife.

Euler underwent the operation of couching, which was attended with the happy result of restoring his sight; but whether from the negligence of his surgeon, or from his being too eager to avail himself of his new organs, he again lost his sight, and suffered much severe pain from the relapse. His love for science, however, continued unabated, and in the course of seven years, he transmitted 70 memoirs to the Academy of St Petersburg. On the 7th of September 1783, after having amused himself with calculating upon a slate the laws of the ascensional motion of balloons, which, at that time, occupied the attention of philosophers, he dined with his relation M. Lexell, and spoke of the planet Herschel, and of the calculations by which its orbit was determined. A short time afterwards, he was amusing himself with one of his grand-children, when, on a sudden, his pipe fell from his hand, and he expired of an apoplectic stroke, in the 76th year of his age.

Euler left behind him three sons, having lost his two daughters in the latter years of his life. Twenty-six out of thirty of his grand-children were alive at the time of his death.

After a long life, so successfully devoted to the sciences, Euler's reputation was very widely extended. Besides being a foreign member of the Academy of Sciences at Paris, he was a Fellow of the Royal Society of London, and he had received from most of the Princes of the North, with whom he was well acquainted, the most flattering marks of their esteem. When the Prince Royal of Prussia visited St Petersburg, he anticipated the visit of Euler, and passed several hours at the bedside of this great man, holding him all the time by the hand, and having, at the same time, upon his knee, one of Euler's grand-children, who had displayed a premature attachment to geometry. The death of Euler was considered as a public loss even in the country where he lived; and the Academy of St Petersburg decreed to him, at their own expense, a marble bust, which was placed in their public hall. In an allegorical picture which the Academy had put up during his life, Geometry was represented as placed upon a pedestal covered with calculations. These calculations were the formulæ of Euler's Theory of the Lunar Motions.

Euler's knowledge was not limited to mathematics and the physical sciences. He had carefully studied anatomy, chemistry, and botany, and he was also deeply versed in ancient literature. He could repeat the Æneid from the beginning to the end, and he could even tell the first and last lines in every page of the edition which he used. In one of his works there is a learned memoir on a question in mechanics, of which, as he himself informs us, a verse of the Æneid gave him the first idea.

Euler possessed naturally a strong constitution; and when we consider the nature of his studies, and the assiduity with which he pursued them, we cannot fail to be surprised at the great degree of health which he enjoyed. In all his habits he was sober and temperate; in his manners unaffected and pleasing, and in his temper lively and cheerful. In his moral and religious character there is much to admire. The high fame which he acquired, and the interruptions which he must have experienced both at Berlin and St Petersburg, never induced him to abandon the religious duties to which he had been educated. As long as he preserved his sight, he assembled the whole of his family every evening, and read a chapter of the Bible, which he accompanied with an exhortation. Theology was one of his favourite studies, and his doctrines were the most rigid doctrines of Calvinism, the only system of religious truth which a philosopher can maintain.

The following is a list of the principal works which Euler published in a separate form. His papers which appeared in the Memoirs of the Academies of Berlin and St Petersburg, are extremely numerous; and he left behind him no fewer than 200 ready for publication, in order to fulfil a promise which he had made to Count Orloff, to supply memoirs for the Acta Petropolitana for twenty years after his death.

*Disquisition Physica de Son.* Basle, 1727.

*Teletamen nova theoria musicar.* Petropli, 1739. This work contains many new views; but as M. Fuss remarks, it had no great success, as it contained too much geometry for musicians, and too much music for geometers.

*Methodus inveniendi lineas curvas maximi minimae proprietate gaudentes.* Lausanne, 1744, 4to.

*Introductio in Analytia Infinitorum.* Lausanne, 1744, 2 vols. 4to. This work, which had become very scarce, was reprinted at Lyons in 1797. It was translated into French in 1796, by J. B. Labey, and published at Paris.

*Theoria motuum planetarum et cometarum.* Berolini, 1744.

*Opuscula varii argumenti.* Berolini, 1746, 1750, 1751, 3 vols. in 4to. The tables of the sun and moon, which are sometimes to be found separately, form part of the 1st volume of this collection. As the three volumes make only 600 pages, they are generally found in one.
Scientia navalis, seu tractatus de constructus ac dirigendis navibus. Petropoli, 1749, 2 vols. 4to.

Theoria motus lunae exhibens onces corporum inqualitates cum additamento. Berolini, 1753, 4to.

Dissertatio de principiis minime actionis, a com examinata. Cl. Koenigii, contra hoc principium factum. Berolini, 1753, 4to.

Institutiones calculi differentialis, cum ejus usu in analysis infinitarum et doctrina serierum. Berolini, 1755. Another edition of this was published in 1787, in 2 vols. 4to, and another at St Petersburg in 1804, in 2 vols. 4to.

Construction plani objectarum ex duplici volto. Petrosp., 1792.

Medituationes de perturbatione motus cometaiarum ab attractione planetarum orta. Petrosp., 1792, 4to.

Theoria motus corporum solidorum seu rigidorum. Rostochii, 1765, 4to.

Institutiones Calculi Integralis. Petrosp., 1768-1770, 3 vols. 4to. Another edition, more correct, was published at Petersburg in 1792 and 1794, in four vols. 4to.

Opuscula Analytica. Petrosp., 1783, 1785, 2 vols. 4to.

Lettres a une Princesse d'Allemagne sur quelques sujets de Physique et de Philosophie. Petrosp., 1768, 1772, 3 vols. 8vo. Another edition of this was published at Berne in 1778, in 3 vols. 8vo. An edition was published in Paris, with notes by Condorcet, and another in 1812, by J. B. Lobey.

Elements d'Algèbre trad. de l'Allemand, par J. Bernoulli, avec des notes par Lagrange et Garnier. Paris, 1807, 2 vols. 8vo. Two editions of this work were published at Lyons in 1774, and 1795, and an edition appeared in London translated into English.

Theorie complete de la construction et de la manoeuvre des vaisseaux, (le style retouché par Keralio.) Paris 1776, 8vo. The original edition of this work appeared at St Petersburg in 1773.

A collection of the best productions of Euler appeared at Brienne in 1797, in 18 volumes.

A more extended list of the writings of this illustrious mathematician, will be found in his Elogy by Nicholas Fuss, which was published at St Petersburg, in 1783, in 4to. (b)

EVOCATION, is the name of a religious ceremony which was always observed by the Romans, when they began the siege of a town, and which they considered as necessary to their success. It consisted in calling upon the gods and goddesses of the place to forsake the town and come over to them. See Macrobius, Sat. iii. 9. (c)

EVOLUTION. See FLUXIONS.

EVOLUTION. See Algebra, and Arithmetic.

EYORA, or EVORA, formerly Ebroa, and the Libraetid Atlas of Julius Caesar, is a city of Portugal, and the principal town in the province of Alentejo. It is the seat of an archbishop, a corregidor, a provost, a juiz, &c. Evora is situated upon a gentle eminence, in a fruitful plain, in the centre of the province, and is surrounded by hills. It consists of narrow crooked streets full of angles, and is distinguished from almost every other town in the kingdom, by its high Gothic buildings, and a number of old Gothic churches. The houses are in general small and low. The cathedral church is situated in the highest part of the town, and has 25 prebends, each of whom enjoys an annual income of 5000 crusades. The archbishop's house adjoins the cathedral, and not far from it are the shambles, an old Roman building, in which admirably preserved Corinthian columns are connected by a plaster wall. These columns, seven in number, are remarkably beautiful, and a drawing of them has been given by Murphy. It is said to be the remains of a temple of Diana. Before it was converted into the shambles, it had been used by the Moors as a mosque. In the great square, and in other parts of the town, there are many other remains of Roman architecture. On the north side, the aqueduct enters the town. It was begun by Ser- التن, but was entirely rebuilt by John III. When Mr Link visited this town, a large and massive edifice was building for barracks, which, when finished, will, he supposes, be unique in its kind in Portugal.

Evora was formerly the seat of an university, but it has totally fallen into decay since the time of Pombal. There are no manufactures, and no trade in the town. It contains five parish churches and 23 religious houses. It is defended by twelve bastions, and two demi-bastions. "On the north side of Evora," says Mr Link, "the hills rise, being rounded the town, adorned with gardens, and on their summits with evergreen oaks. The road from hence to Montemor o Novo, which is five leagues distant, passes over granite hills, partly covered with corn fields and partly with fine woods of evergreen, oaks, and pastures, which give great variety to the prospect." Population 12,000.

EUPHRATES, or more properly called the Phrat, from the Hebrew Phar, or Pharaz, to spread, and Pharaq, to produce fruit or flowers; a river of Asia, which, with the Tigris, forms the western boundary of the Persian empire.

The Euphrates has two principal sources in the mountains of Armenia; the first of these is called Al- la, issuing from a mountain in the vicinity of the towns of Bayazid and Diadin, and receives in its course the tribute of six springs from Shehrian, Malasjird, Khunnoos, Chaharbore, Nizamajird, and Kague. The second is formed by the confluence of many streams from the mountains around Erzeroum, and is called the Karasu, from the blackness of its water.

These two streams pursue a westerly direction, and unite near the town of Kebban, in the recesses of Mount Taurus, when the river inclines to the south-west, and passes within a few miles of the walls of Malatea. Receiving at Malatea another tributary stream, it approaches the Mediterranean, till it is forced into a south-east course by the mountains in the neighbourhood of Samosata. Though not so rapid, the Euphrates is a much finer river than the Tigris; while the latter at Argumna is but a little brook, the Euphrates is 100 yards broad at Malatea, and at Ul Der, or the ancient Thapsaeus, 800. Ten miles from the village of Lemloot, situated about half way between Bussora and Hillah, its waters are diffused over an immense morass, and are again collected about 21 miles north of Samavat. These marshes have been much increased since 1784, when the Great Soliman Pasha threw a bank across the river at Delva- nio, to divert the course of the river into an old channel, for the purpose of attacking with advantage the Alghazil Arabs. At Korna, about 130 miles distant from its mouth, the Euphrates joins the Tigris; their united streams receive the name of the Shat ol Arab, and form one of the noblest rivers in the East. The force of the flood-tide prevails so much at Korna, that, from
Even navigated, advances of navigable half-moon canals or nearly and of the river, and Sitrig is one of the three Aphanas built by Seleucus, in honour of his first wife Apama, and is situated at the point of a triangle, formed by the confluence of these two streams. Sir John Malcolm, sent as ambassador from India to the court of Persia by the Marquis Wellesley, considering the position of Kor-nass peculiarly advantageous, and where an impregnable fort might be erected at a trifling expense, which would secure the navigation of both rivers, repels the inroads of the neighbouring Arabs, and command the countries between Bagdad and Bushorra, recommended this object as worthy of the attention of the governor-general of India. Here the channels of the Euphrates and Tigiris are so deep, that a small ship of war might anchor close to the works, and a canal cut across the base of the triangle, from one river to the other, would render any other fortification unnecessary.

Polybius observes, that the Euphrates is remarkable for differing, in this respect from most others in the world. Rivers, in general, he remarks, increase in size as they advance in their course, their waters swelling in winter and decreasing in summer. The Euphrates, on the contrary, diminishes as it flows, is very high in the middle of summer, and no where so broad as in Syria. This is accounted for from its increase being the effect of the dissolution of snows in the mountains, and not of winter rains; canals and reservoirs being employed to draw off the superabundant waters for irrigating the districts on its banks, it decreases as it traverses an extent of country.

Captain M. Kinneir, author of a Geographical Memoir of the Persian Empire, who must be supposed the safest authority to follow, writing from actual observation on the spot, and to whom we are indebted for much interesting information on this subject, says, that the greatest rise of the Euphrates is in January, when it attains an increase of 12 feet perpendicular; and it continues to rise and fall till the end of May or beginning of June. Here is a manifest contradiction of Polybius, which we cannot hope to reconcile, as it probably proceeds from some change in the manner in which the river is now affected, unknown to us. However, in justice to Polybius, who is esteemed an excellent historian, and drew from the best sources within his reach, we must observe that that part of his account where he mentions that the Euphrates decreases in size as it advances in its course, is supported by Kinneir; for this author states that at Hilah, near the ancient Babylon, the Euphrates is only 200 paces broad, and 40 feet deep. Now Hilah is much below Ul Der, where it is 800 yards broad. Perhaps the great depth of 40 feet may be thought to compensate in some degree the breadth so much higher up; but we are not warranted to draw this conclusion, as Kinneir has not given us the depth of the river at Ul Der. Even in the driest season, the Euphrates is navigable for boats of considerable burden, up as far as Shukashu, a village situated on the east bank of the river, and a day's sail from Korna. The tides of the Persian Gulf reach 20 or 25 miles above Korna; and the river is navigated, during six months of the year, by flat bottomed boats up to Hil-lahs. These boats are of a singular construction. The body resembles a half-moon in shape; the ribs and planks are roughly nailed together, and the outside covered with naptha or bitumen; there is no keel, and the rudder, formed of a number of spars clung together, is nearly as large as the vessel; the rigging consists of one mast and a lateen sail. When proceeding to Busorda, they float down the stream; on their return, they are tracked up against the current. Another kind of boat, perfectly round, made of wicker work, covered with bitumen, and about seven feet in diameter, called a Kufa, is much used on the Euphrates and Tigiris. Herodotus mentions circular boats made of reeds, in the form of a shield; and, as Captain Kinneir remarks, it is curious to observe that so little alteration in their construction has taken place during such a lapse of ages.

No subject has excited more the attention of the learned than the river Euphrates, with regard to its great canals and artificial lakes, dug for the reception of its waters at the season of inundation. Of the ancient authorities, Arrian is the most explicit, and who, Dr Vincent in his learned work on the voyage of Nearchus, says, possesses the peculiar felicity of rising in estimation in proportion to the attention paid to his relations, the purity of the sources whence he drew, has been established by subsequent discovery and investigation. The canal of Pallacopas, dug by the first of the Babylonian kings, is still in existence; but, since the desertion of Kufa, having fallen into disrepair, about twenty years ago it was partially cleared by the Nabob of Oude, in honour of whom the Arabs now call it Hindi. It is cut from the right bank of the Euphrates, and that part of it which still holds water, extends to within five miles of the town of Meshed Ali, or Nejiff. The remainder is nearly chokd up with sand, but its course may be traced from the Bahr Nejiff, or Sea of Nejiff, to the town of Zobeir, and to its termination at the Khore Abdallah in the Persian Gulf. In the neighbourhood of Babylon are still the remains of two lakes, celebrated by the names of Ali and his son Hussein. The upper lake lies nearly on the parallel of Babylon: At its northern extremity stands the town of Kerbela, containing the tomb of Hussein, the grandson of Mahomed. From the southern extremity of this lake to the northern point of the lower, or Bahr Nejiff, the distance is about twenty-five miles. Meshed Ali is situated a little to the east. Into this lower lake the Euphrates was turned by the canal of Pallacopas, at the season of its floods. The opening and shutting of this canal was a part of the office of the sultan of Babylon; and, as Dr Vincent remarks, it must have been a duty of the highest importance, in a tract of country where all is desert that cannot be watered, and every spot fertile that can be flooded.

When Babylon was the capital of the East, the command of the waters of the Euphrates was highly necessary for the cultivation of the adjacent districts; and thus, as the cities in the vicinity of its banks have flourished or decayed, its canals and dikes have been preserved or neglected. And though its grand canals have failed, the ruinous policy of the Turks, at this day, regards the partial distribution of its waters as an object of primary importance for the purpose of irrigation. Arrian gives us the following account of the origin and object of the canal of Pallacopas, cut from the Euphrates to draw off its superabundant waters. For this river, he tells us, descending from the mountains of Armenia, flows within its natural channel during winter, but receives such an accession of water in the beginning of spring, and a still greater about the summer solstice, that, overflowing its banks, it pays under water the plains of Assyria. And unless this inundation, caused by the dissolution of snows in the mountains,
EUPHRATES were diffused by means of the cut of Pallacopas over lakes and marshes, the whole of the surrounding country would be desolated. The waters thus drawn off, reach the main by a diversity of subterranean courses. Though the Euphrates again decreases after the dissolution and discharge of the snows, yet so great a part of its waters flow through the Pallacopas, that had not means been adopted to bank up this channel, and conduce the river within its natural limits, the whole Euphrates would probably discharge itself in this direction, and refuse its waters to irrigate and fertilize the plains of Assyria. On this account the Satrap of Babylonia, at a great expense of labour, cut off the communication, although the work, on being completed, was found to be insufficient; the embankment being composed of mud and such like materials, was incapable of resisting the pressure of the water, and continued to yield it a passage through the canal. Alexander, consulting the advantage of Assyria, shut out the waters by a more solid and permanent work. At a short distance, a rocky soil was found, which, when cut through, and prolonged to the Pallacopas, offered the double advantage of conducting the superabundant waters, without injury to its banks, and of affording a good foundation for the construction of works and sluices to admit the waters of the Euphrates at its season of inundation, and to exclude them effectually when the floods had subsided, and when it became necessary to confine the river within its natural channel, for the cultivation of Assyria. This the Wahabees, in order to distress the city, broke down, so that when Captain Kinneir was at Mesheel Ali, in 1808, the inhabitants of the town were obliged to bring their water in sheep skins, from a distance of three or four miles.

The Euphrates, or sea of Nejiff, (the Rahemah of D'Amville) is of equal antiquity with the Pallacopas, and a work of infinite labour. The above mentioned gentleman passed through the middle of it, in his way from Samnwat to Mesheel Ali, and found it dry, with the exception of a few ravines and channels of water, near which the poorer classes rear rice and vegetables. There are other canals which deserve notice. Of these, the canal of Kerbela, or Nahr Sares, now called Husseinie, at the extremity of which is the large and populous town of Kerbela, or Mesheed Hussein, is a very fine one, though more ancient than the days of Alexander, and supposed at one time to have been connected with the Bahir Nejiff. Of the canal of Isu, which is said to have commenced at Is, the modern Hit, and to have terminated at Opis, connecting the Euphrates and Tigris, not a trace now remains. The only canal at present communicating with the two rivers, is called the He. It cuts the Jesira exactly half way between Busorsi and Bagdad, and in spring is navigable for large boats.

At the small town of Hit, which furnished the bitumen of which the walls of Babylonia were built, a bridge of boats is thrown across the Euphrates, for the convenience of the caravans of Bagdad and Aleppo. There is a bridge of 15 arches at the town of Argish, three days journey from Van, situated on the north-west side of the lake of the same name, which is about 168 miles in circumference, but whose water is so brackish as to be unfit for use.

It is well known that the Euphrates divided the city Babylon into two equal parts, flowing through it by the river of the same name, from north to south. Its banks were faced with bricks, the inhabitants descending by steps through small brass gates in a lofty wall, parallel with the river. Semiramis threw across a bridge of five fortresses, 1500 feet in length, and 30 feet in breadth, to connect the two quarters of the city, and erected a palace at end of the bridge. These palaces communicated with each other, by means of a vaulted passage cut under the bed of the river, for which purpose an immense lake was dug, into which its waters were turned. The course of the river, Kinneir remarks, might easily be diverted, as the banks of the Euphrates rise above the level of the adjoining plain; but, as he adds, it is difficult to conceive how it could be confined within the compass of an artificial lake, without inundating the surrounding country, or forcing a passage to the sea. The waters of the Euphrates were again diverted by Cyrus, when he took Babylon. Taking advantage of a great festival held in the city, and when all its inhabitants were immersed in debauchery and revelling, he posted a part of his troops, destined for the attack, on that side where the Euphrates entered the town, and another division on the side whence it issued out, giving orders that they should enter the city by marching along the bed of the river, as soon as they found it fordable. In the evening, he caused the great receptacles and canals above and below the town to be opened. By this means the Euphrates was discharged, and its natural channel left dry. The enterprise was greatly facilitated, and, perhaps, solely accomplished, in consequence of the negligence and disorder of the city, as that night the gates of brass which shut up the avenues from the river to the town were left open.

When Kinneir examined the ruins of Babylon, he Pyramid of Nebuchadnezzar particularly a pyramid, six miles south-west Nimrud, of Hillah, called Ninrood by the Arabs, about 50 feet in height, from whose summit the windings of the Euphrates may be traced through the level plain of Shinar. Villages and orchards are seen to line its banks, while a few hamlets, interspersed here and there on the desert, appear like spots on the surface of the ocean. Though the Euphrates flows through one of the most productive regions of the earth, the pernicious policy of the Turk renders unavailing the bounty of nature, the baneful influence of despotism converting fertile plains into sterility, and the habituation of wild beasts. On those banks where once flourished the proudest cities of the world, now languish comparatively insignificant towns; where luxury and abundance were universally diffused, a scanty pitance is now gathered; and where mighty conquerors have contended for kingdoms, the wandering Arab of the desert now vindicates his spoil. But the whole extent of country along the banks of the Euphrates must not be included in this picture of desolation. The description of Armenia, through considerable part of which this river flows, appeared so delightful to the imagination of poetry, that Milton has fixed here the terrestrial seat of paradise.

From Auran, eastward to the royal towers.
EUPHRATES.

Of great Sacleus, built by Grecian kings, where the sons of Eden long before Dwelt in Telassar.

Par. Lost. Book IV.

Of great Sacleus, built by Grecian kings, where the sons of Eden long before Dwelt in Telassar.

The borders of the Euphrates between Korna and Shinkashar produce dry grain in abundance, and the territory of the Alghanif Arabs, a low marshy tract, formed by the expansion of its waters between Lemenio and Samavat, is celebrated for its crops of rice. There is an excellent breed of horses on the banks of this river, in the district inhabited by the tribe of Montefil, numerous numbers of which have lately been exported to India, by Mr Manesty, the British Resident at Busurra. A very high bred horse, however, is difficult to be procured, even at Bagdad or Busurra, and will fetch from 1200 to 3000 piastres, or about from L. 120 to L. 300 sterling.

In noticing the mouth of the Euphrates, we shall attend chiefly to what Kinneir says on the subject. This has given occasion to a great deal of discussion. Dr Vincent has bestowed much pains and argument in elucidating the matter, and D'Anville has been led into gross mistakes, from ignorance on some particular points of inquiry. But Kinneir having been encamped for six months on the banks of the Karoon and Hafar, must be supposed, from his intelligence, and opportunity of investigation, eminently qualified to give correct information, and to settle disputed points.

It has generally, though erroneously, been supposed, that the Shat-ool-Arab, (the combined stream of the Euphrates and Tigris,) enters the Persian Gulf by a variety of mouths. This mistake has probably arisen from the ignorance of navigators, about the rivers of Susiana, concerning that the seven channels which issue from the Delta into the sea, at no great distance from each other, were derived from the Shat-ool-Arab, the river with which they were chiefly acquainted. These channels, or kpheres as they are called, in Mr Cluets map preserve the following order: Cossisa Bouny, Bamishere, Karoon, Seluge, Mohilla, Goban, and Deria Bouny. If it be proved that the Bamishere, the next in succession, as well as in magnitude, to the Cossisa Bouny, or Shat-ool-Arab, is not in the least augmented by the waters of the latter, clearly none of the others can; for the only means of communication is by the Hafar cut. Now, the Bamishere is the main stream of the Karoon. This river, after its confluence with the Abzial at Budikile, contains perhaps a greater body of water than either the Euphrates or Tigris separately. This stream, on reaching Sabla, a ruined village 30 miles east of Busurra, dissinities; the largest branch called Hafar, after a course of fourteen or fifteen miles, again separates. The greatest portion of waters flowing obliquely to the sea, that constitute the Bamishere, and the rest enter the Shat-ool-Arab, through an artificial cut, three miles long. This is the only communication which the Shat-ool-Arab has with the six eastern channels; and as the waters of the Karoon constantly flow through it into that river, not those of the Shat-ool-Arab into the Karoon, it is evident that neither the Bamishere, nor the other kpheres, are derived from the combined stream of the Euphrates and Tigris, which, on approaching the Gulf, receives the name of the Cossisa Bouny.

The Euphrates, according to Arrian and Strabo, entered the Persian Gulf by a separate channel, afterwards obstructed and turned by the citizens of Orchus. This opinion has been acquiesced in by D'Anville. Vincent, however, thinks this erroneous, and tries to prove that the Pallacopas canal passing near the city of Orchus, and entering the gulf in the Khore Abdal-lah, was mistaken by the ancients for the mouth of the Euphrates. The five remaining channels are ramifications of the Karoon, which takes an easterly direction towards the Delta of Goban, on separating from the main stream of the Sabla. Before Sheikhol Solyman raised his mound, or embankment, at Sabla, the Bamishere was the channel usually navigated by ships bound to Busurra. They pass through the Hafar cut, which is at least 150 yards wide, and, at high water, deep enough to admit of a vessel of size.

Nearcues, on his voyage from the Indus to the Euphrates, entering the channel called by Arrian, Pasithrigis, now known by the name of the Karoon, conducted his fleet up to Susa, and thence descending with a division of his ships through the Hafar cut, which thus appears to be of greater antiquity than the days of Alexander, passed into the Shat-ool-Arab. Some ships, commanded by Nearcues in person, sailed up the Euphrates as far as Babylon. At Babylon the death of Alexander terminated the further prosecution of an enterprise, which extended to the circumnavigation of Arabia, up the Red Sea to Suez. A plan worthy of the comprehensive genius of the illustrious projector of a voyage, which must be considered as the most interesting in the world, at the time of its accomplishment, opening a communication with Europe and the most distant regions of Asia, and, as Dr Vincent observes, the source and origin of the Portuguese discoveries, and the primary cause, however remote, of the British establishments in India.

From its source, the Euphrates performs a course of about 1400 miles to its confluence with the Tigris at Korna, which, estimating at the distance of 180 miles from the Persian Gulf, the waters of the Euphrates consequently flow upwards of 1500 miles in reaching the sea.

See Kinneir's Geographical Memoir of the Persian Empire, passim, and the accompanying Map; Memoire sur l'Euphrate et le Tigre par D'Anville; Vincent's Voyage of Nearcues, and Arrian's Hist. by Gronovius (v. t.).

EURIPIDES, a celebrated Grecian tragic poet, was born in the first year of the 75th Olympiad, (about 468 B. C.) in the island of Salamis, whither his parents had retired, a short time previous to the invasion of Attica by Xerxes. In consequence of the false interpretation of an equivocal oracle, he was destined, by his father, for the profession of an athletic champion; but his own natural genius soon directed him to very different pursuits. He is said to have studied rhetoric under Prodacus, natural philosophy under Anaxagoras, and morals under Socrates. This last, however, although affirmed by various authors, appears to be a mistake; for, upon the reference to chronology, it will be found, that Socrates was twelve or thirteen years younger than Euripides; which makes it very improbable that the latter could have stood in the relation of pupil to the former. But it is pretty certain, that a great friendship and intimacy subsisted between these two eminent men; in so much that Socrates, who in general disapproved of dramatic exhibitions, seldom appeared at the theatre, unless when the tragedies of Euripides were to be performed.

At an early age, Euripides imbued a strong partiality for the study of philosophy; but perceiving the dangers and persecutions to which those exposed themselves, who ventured to combat vulgar prejudices, and to controvert the popular opinions, he was induced to abandon his favourite pursuits, and devoted himself,
from his eighteenth year, to the composition of dramatic poetry, in which he soon rose to the highest eminence. He wrote a great number of tragedies, which were held in the highest estimation during his own time, and have been admired by the best scholars and most learned critics of all ages. He was the contemporary and rival of Sophocles, with whom he repeatedly contested the palm of superiority in the composition of tragic poetry. Like many of the great men of that age, he experienced the biting ridicule of the celebrated comic writer Aristophanes; and, in consequence of the sarcasms of that formidable wit, it is said he resolved to withdraw from Athens to the court of Archelaus of Macedon, a great patron of learned men, by whom he was hospitably received, and raised to high honours. Here, however, he met with a most tragic fate; for, while he was walking in a wood, according to his custom, absorbed in profound meditation, he was encountered and torn to pieces by the prince's dogs, who happened to be at that time engaged in hunting. Archelaus lamented his death, and gave him a magnificent funeral. When the news of his fate reached Athens, the inhabitants were so grieved at the event, that the whole city went into mourning. His great rival Sophocles, with a soul superior to vulgar jealousy, also manifested his grief in the most unequivocal manner. He ordered a tragedy to be performed upon the occasion, at which he himself and the actors appeared in deep mourning. The circumstances of the death of Euripides, however, are variously reported; but we have given the most current tradition regarding it; and the event seems to have happened when he was about 75 years of age.

Euripides is said to have been the author of ninety-two tragedies, of which nineteen still remain. His performances seldom gained the prize; yet they were esteemed by the Greeks, and strongly venerated among the Sicilians, that when the Athenian army, commanded by Nicias, was defeated in Sicily, the soldiers purchased their lives and liberties by reciting the verses of Euripides. His plays abound so much in moral sentences, and philosophical maxims, that he was called the philosopher of the stage. By many, he has been considered as the most accomplished of all the ancient tragic poets, although the critics are divided in their opinions concerning the superior claims of Aeschylus, Sophocles, and the subject of this article. Quintilian seems unwilling to decide, yet he evidently gives the palm to Euripides, (Inst. Or. lib. x. cap. 1.) He is inferior to the two first, perhaps, in majesty, sublimity, and force; but he is generally allowed to surpass them in morality and pathos; and in the declamatory eloquence of the stage he is probably unrivalled. Aristotle calls him the most tragic of all the poets.

Euripides introduced some improvements into the composition of tragedy. Among other changes, he suppressed the prologue, in which it had been usual to give an outline of the story, and threw the exposition of the subject into the piece itself; a mode of proceeding, which, although it presented some difficulties to the author, was of considerable advantage to the dramatic art.

The manners of Euripides were harsh, and his character austere; but his dramatic productions, in general, do not indicate such dispositions; for there is no poet who has written with greater feeling and tenderness, or who has described the passion of love in more expressive and delicate terms. He is said, however, to have had two wives, whose character and conduct were far from contributing to soften the asperity of his temper; and he acquired the name of the woman hater, probably in consequence of the many invectives which, in his writings, he pointed against the fair sex.

The earliest edition of Euripides is that of Aldus Manutius, Venice, 1503, 8vo. It contains only the Greek text of eighteen tragedies. This edition was renewed by Hervagius, Basil, 1537, &c. Robert Winter published another edition at Basil, in 1541, with a Latin version. John Oporin printed an edition of Euripides, in Greek and Latin, 1562, fol. Plantinus gave an edition at Antwerp, 1571, 16mo, with the division and arrangement of the verses by William Canter. Besides these, we have the edition of Jerome Comminus, Heidelberg, 1597, 8vo; of Paul Stevens, 1604, 4to; and of Joshua Barnes, Cambridge, 1694, fol., with a life prefixed, and learned notes. Some tragedies have been printed separately, and commented upon, by different editors. The excellent English translation of Euripides by Potter, is well known (2)

**EUROPE.**

Europe is the name given to one of the four great divisions into which geographers have divided the earth. Though much the smallest, it is by far the most important and powerful, and indeed governs almost all the others. In the warmth of its climate, the fertility of its soil, and the richness and luxuriance of its productions, Europe is perhaps the least favoured quarter of the world. But in the political strength and greatness of the nations which inhabit it, in civilization and refinement, in attainments in science, and in all the useful and ornamental arts, the superiority is vast and striking. Here is the theatre on which the human character has appeared to the greatest advantage, and where society has attained its most perfect form, both in ancient and modern times; and this smallest portion of the globe, seems destined to extend knowledge and improvement over the rest of the world.

The origin of the name *Europe* is not certainly known; but it seems to have been extended from that of a small district on the European side of the Hellespont, as the name of Asia spread from the name of the country on the opposite shore. The extent of this part of the globe, which yields considerably even to Africa, is from the most western point of Portugal near Lisbon, to the Urallian mountains on the east, in length about 3900 British miles, and in breadth, from the North Cape in Lapland to the southern extremity of Greece, about 2850. The contents in square miles, though they cannot be calculated with any degree of accuracy, may be stated at the median number of two millions and a half. The boundaries of Europe. The ancients were but very imperfectly acquainted with the boundaries of Europe. A great proportion of this division, especially in the north and east, has never been known with any degree of precision until modern times. It is bounded on the north by the Arctic Ocean, or Frozen Sea; on the west by the Atlantic Ocean; and on the south by the Mediterranean Sea. Its eastern limits are not so well defined. As the natural boundaries on this side extend only a certain length, it is separated from Asia in many places merely by arbitrary li-
EUROPE.

The line which divides those two quarters of the globe, is generally understood, however, to proceed along the Uralian mountains, down the small river Karporks, the great river Don, and through the Sea of Azof, the Black Sea, the Hellespont, the Sea of Marmora, and the Dardanelles into the Mediterranean.

There are in Europe no great natural divisions, unless we consider it as divided by the Baltic into the countries north and south of that sea. On the north of the Baltic, are the northern or Scandinavian kingdoms, Denmark, Norway, and Sweden. The extensive empire of Russia, occupies the remainder of the north and all the east of Europe. In the south, is the European part of the Turkish empire, and the Italian states. In the west, proceeding from south to north, are the kingdoms of Spain and Portugal, France, Holland, and part of Germany. And in the centre of Europe are situated most of the German states, Prussia, Poland, Switzerland, Bohemia, Hungary, &c. During the violent and extraordinary convulsions which for the last twenty years have agitated and desolated this division of the globe, it has often been difficult to say what were the limits, or who were the masters of many of its states and kingdoms; but now that the storm has subsided, they are again returning to nearly their former boundaries, their former governments, and their former institutions.

The European islands are numerous, and some of them extensive and highly important. On the west of the Atlantic Ocean, are the Azores, situated about thirteen degrees west of Cape St Vincent in Portugal. Though frequently classed under Africa, they more properly belong to Europe, to which they are nearer, from which they were peopled, and to which they have always been subject. The British isles, consisting of Great Britain and Ireland, with the numerous circumjacent islands belonging to them, the seat of the greatest and most powerful empire on the face of the earth. The Baltic, Danish, Russian, Venetian, Sicilian, and Genoese islands are other important islands on the Norwegian coast.

The Faroe islands, belonging to the crown of Denmark. The Faeroe islands and the island of Iceland, subject to the crown of Denmark, are 1,000 miles from the continent in the Western Ocean; and numerous other but unimportant islands on the Norwegian coast.

In the North Sea, the chief and most extensive are the British isles, the islands of Denmark, Zealand, the chief seat of the Danish monarchy, Funen, Lolland, Falster, Bornholm, &c.; the islands of Rugen, Oeland, Gotland, and Aland, belonging to Sweden; and those of Gronstadt, Oesal, Dago, &c. subject to Russia. In the Mediterranean, are the islands of Majorca and Minorca, of Corsica and Sardinia, the large and fertile island of Sicily, Malta, Candia the ancient Crete, Negropont the ancient Euboea, with the numerous other islands of the Grecian Archipelago.

Europe contains numerous peninsulas. Some of its finest and most celebrated regions are peninsular. Besides innumerable others of lesser extent and importance, we may notice Crim-Tartary in the Black Sea; the peninsulas of Greece and of Italy in the Mediterranean; Spain and Portugal, contained between the Mediterranean and the Atlantic; and Jutland, formed by the Atlantic and the Baltic. We may include also Scandinavia, which is only a large peninsula formed by the Baltic and the Northern Ocean.

The mountains of Europe do not form ridges of such vast extent as those of Asia, and are much inferior in height to those in Thibet and in South America. Of the European mountains, the Alps undoubtedly hold the first place. They extend, in a kind of semicircular form, from the Gulf of Genoa, through Switzerland, which contains their centre and highest parts, and terminate in the Carnic Alps, on the north of the Adriatic Sea—a length of about 550 British miles. Mount Blanc, the highest point of the Alpine chain, and the greatest elevation of the ancient continent, rises 15,062 feet above the level of the sea. Next to the Alps are the Pyrenees, which divide France from Spain, extending between the Atlantic and the Mediterranean. Mount Perdu, which is considered as the highest elevation of the Pyrenees, ascends above the level of the sea about 11,000 feet. Between Norway and Sweden runs the extensive Scandinavian chain, known by distinct appellations as it passes through different provinces. The elevation of these mountains have not been very accurately ascertained; but they do not equal the Alps, or even the Pyrenees. The grand and extensive ridge of the Carpathian mountains extends, in a semicircular form, from the mountain of Javornick, south of Silisia, bounds Hungary on the north and east, and sends off branches to Transylvania and Wallachia. Its whole circuit may be about 500 miles; and the highest summits of these mountains do not exceed 5000 or 9000 feet. On the south of the Danube, in Turkey, runs the grand range of the Haemus, stretching from Eminch to the south of Servia, a tract of 400 miles, known under various names. From the western extremity of the Haemus branch off two other extensive chains, one running between Dalmatia and Bosnia; the other passing south, and forming the mountains of Albania on the west of Greece. The Appenines, branching off from the Alps near Ormae, separate the plains of Piedmont from the sea, and stretch, in one extensive and uninterrupted chain, through the whole length of Italy to its farthest extremities. Of the volcanic mountains of Europe, mount Aetna, in Sicily, claims the first distinction. The other volcanoes are of Mount Vesuvius near Naples, and Mount Hecla in Iceland. The islands of Lipari, to the north of Sicily, also contain many volcanoes, of which Stromboli is the chief. The European mountains which we have enumerated, with various others of inferior importance, will be more minutely described under their own names, or under the different countries to which they belong.

On the west of Europe flows the great Atlantic Ocean, which separates it from the new continent of America. To different parts of this sea local names have been given, from the coasts washed by its waves: As the German Sea, flowing between Great Britain and the opposite shores of Germany and Denmark; the British Channel, between the south of England and the coast of France; St George's Channel and the Irish Sea, between Great Britain and Ireland; the Bay of Biscay, between France and Spain, &c. On the European coasts of the Atlantic Ocean are various extensive banks or shoals, the resort of cod and other fish, which prove a useful source of industry and subsistence to the inhabitants. To the north of Europe lies the Arctic Ocean, extending over the polar regions, the dreary and solitary abode of cold and ice; yet even this enormous and apparently barren waste furnishes a form of provision for the human race. Here the vast and innumerable tribes of herrings find a retreat from their numerous foes; and breed their millions in safety. About the middle of winter they come forth from their retreat, and spread themselves in three divisions. One directs its course westward, and...
reaches the shores of America; another smaller squadron passes through the Straits of Behring, and visits the north-eastern coasts of Asia. The principal division reaches Iceland about the beginning of March, in a close shod of surprising depth, and of such extent, that its surface is supposed to equal the dimensions of Great Britain and Ireland. They are afterwards, however, subdivided into numerous smaller columns of five or six miles in length, and three or four in breadth, which arrive during spring and summer on different parts of the north-western coasts of Europe. The whale fisheries, too, which these northern seas supply, is another source of considerable wealth to various of the European nations.

In crossing the continent of Europe, one of its most striking and important features, is the number and extent of its inland seas; which have been justly regarded as one of the chief causes of its industry and civilization, and consequent superiority to the other grand divisions of the globe. Amongst these, the Mediterranean is obviously pre-eminent. From its shores, their first seats, both in ancient and modern times, knowledge and civilization have been diffused over the other countries of Europe. From the Pillars of Hercules, on the west where it communicates with the Atlantic, it penetrates between the continents of Europe and Africa, as far east as Syria in Asia, a length of 2000 miles, by a breadth of between 400 and 500. On the European side, open two large inlets, the Gulf of Venice and the Archipelago, which still further extend the advantages of inland navigation, which the Mediterranean so eminently affords. The wide expanse of this sea is beautifully sprinkled with islands, and environed with opulent coasts, abounding with the most sublime and picturesque features of nature. In the Mediterranean there are no tides, except in the narrowest straits; but a current sets along the Italian shore from west to east, and towards the African in an opposite direction. This sea abounds in fish. The chief fisheries are those of the tuna, of the sword-fish, of the sea-dog, and of the anchovy. To the north of the eastern part of this sea, which is denominated the Levant, but distant from it some hundreds of miles, lies the Black Sea, with which it communicates by two narrow straits, and the small sea of Marmora, which is situated between them. This extensive sea, of which the western parts only belong to Europe, is said to have derived its name from its black rocks, or dangerous navigation. To the north of the Black Sea, and connected with it by the short and narrow strait of Caffa, is the sea of Azof, the utmost maritime limit of Europe in this quarter. It is shallow, and polluted with mud, whence its ancient name of Pallas Moiris.

Amongst the inland seas of Europe, the Baltic holds the second place. This extensive inlet opens from the German Sea by a gulf, in the direction of N.E., called the Skager Rock, and afterwards turns to the south, in what is called the Cattegat. The Baltic then spreads widely to the N.E. and is divided into two extensive branches, called the Gulfs of Bothnia and Finland, both covered with ice during four or five months of the winter. The greatest depth of this sea does not exceed 50 fathoms; and the Swedish naturalists say that it loses about four feet in extent in the course of a century. Its waters do not contain above 1-50th part of salt, whereas other sea-water often holds a tenth. There are no tides, and the fish are few.

The only other great inland sea of Europe is that called the White Sea, which is an extensive inlet or gulf of the Arctic Ocean, penetrating the northern provinces of Russia in the direction of the Baltic. This sea was better known before the commerce of Archangel was supplanted by that of St. Petersburg.

The numerous and extensive inland seas and gulfs of Straits, Europe, give rise to several celebrated straits. Of these, besides those already mentioned, the most important are, the Straits of Gibraltar, which connect the Mediterranean with the Atlantic Ocean; the Straits of Messinia, between Italy and Sicily; the Dardanelles, between the Grecian Archipelago and the Sea of Marmora; and the Hellespont, between the Sea of Marmora and the Black Sea; the Straits of Dover, which connect the English Channel with the German Sea, and the narrowest distance between the English and French coasts; and, in the Baltic, the celebrated Strait of the Sound, between the Island of Zealand and the coast of Sweden, where the king of Denmark levies a toll on all ships passing up and down the Baltic; the Great Belt, between Zealand and Funen; and the Little Belt, between Funen and the peninsula of Jutland.

Europe contains few or no lakes of any great extent. Lakes. The most considerable are, the lakes of Constance, 45 miles in length, and 15 in breadth; and of Geneva, 40 miles long, and nine at its greatest breadth, both situated in Switzerland. The lakes, Wener, 80 miles in length, and 50 in breadth; Wetter, about 80 miles long, and 12 broad; and Meier, 60 miles by 18, in Sweden. And Lake Onega, which is about 150 miles in length, by a medial breadth of about 30; and the Ladoga, 150 miles long by 70 in breadth, in the western divisions of the Russian empire.

- The more limited extent of Europe admits not the accumulation of such mighty bodies of water as the Asiatic and American continents roll to the ocean. The largest and most important of the European rivers, are, the Volga, the greater part of which belongs to Volga, this division of the globe. This largest of the European rivers takes its rise in the mountains of Valday, between Petersburg and Moscow, and, after running in a south-easterly direction, a course of upwards of 1700 miles, falls into the Caspian at Astracan. This noble river, having no cataracts, and few shoals, is navigable even as high as Tver. Its chief tributary streams are, the Kama on the east, and the Oka on the west.

Next to Volga is the Danube, whose magnificent stream rises in Swabia, and passing through Bavaria, Austria, Hungary, and Turkey, falls into the Black Sea, after a circuit of 1300 miles. The Danube, though occasionally impeded by small falls and whirlpools, is yet navigable through an immense extent of its course. The Dnieper, or ancient Borysthenes, rises in the government of Smolensk, about 150 miles to the south of the source of the Volga, and after a course of about 1000 miles through fertile provinces, falls into the Euxine Sea. The Rhine rises in the mountains of Switzerland, and falls into the German Sea, by several mouths, on the coast of Holland. This noble river, whose banks are celebrated for their grand and striking scenery, forms the great barrier between France and Germany, and its course may be compared to 500 miles. It receives, near Mentz, the tributary stream of the Main.

The Elbe rises in the Sudetic mountains of Silesia, and, running through the north of Germany a course of 500 miles, discharges itself into the sea near Cuxhaven. The Don rises from a lake in the government of Tulan, and falls into the sea of Azof, after a course of about 800 miles. The Dniester forms the boundary of the

White Sea.
Europe.

between European Turkey and Russia, derives its source from the north side of the Carpathian mountains, and falls into the Euxine at Akerman, after a course of about 600 miles. The Dvina and Pelahora direct their course to the Arctic Ocean. The course of the former, which falls into the White Sea, is about 500 miles; and that of the latter 450. The Dvina rises in the province of Smolensk in Russia, and falls into the Baltic at Riga, after running 500 miles. The Vistula rises in the Carpathian mountains, passes Warsaw, and joins the sea near Dantzig, after a course of 450 miles. The Oder has its source in the mountains of Moravia, and, after watering Silesia, Brandenberg, and Pomerania, joins the Baltic, after a course of 380 miles. The Rhone springs from the Glacier of Furca, and, flowing through the Lake of Geneva, bends its course to the south, and enters the Mediterranean; its course is 400 miles. The Loire rises in Languedoc, and after running 500 miles, enters the ocean beyond Nantes. The beautiful stream of the Seine, on which the city of Paris is built, falls into the English Channel at Havre de Grace, after a course of 250 miles. The Ebro rises in the mountains of Asturias in Spain, and after a south-easterly course of 350 miles, falls into the Mediterranean Sea. The Tagus has its source in the west of Arragon, and holding a course of 450 miles, falls into the Atlantic at Lisbon. Nor in enumerating the rivers of Europe, ought we to forget the Thames, which, though one of the smallest, is one of the most celebrated; the seat of British empire, and the grand resort of the commerce of the world.

Climate.

Exepting a small portion of its most northern limits which stretches within the Arctic circle, Europe is entirely situated within the temperate zone, and is consequently exempted from the utmost extremities both of heat and of cold. In so extensive a track, however, the climate must necessarily be very various. While its northern states are often cold and bleak, and during many months lay bound in the frozen chains of winter, one wide expanse of snow, its central regions are generally mild and temperate, and its southern kingdoms enjoy such the most serene, and a climate the purest and most delightful in the world. The climate of no division of the globe is more salubrious than that of almost every part of Europe; and nowhere do the human species live to a more advanced age. The soil of Europe, though it pours not forth its vegetation with the same spontaneous luxuriance as in regions heated by a tropical sun, yet, aided by the hand of industry, and superior skill in agriculture, it supplies more certainly and more abundantly than any other quarter of the earth, subsistence for its numerous population, and furnishes them with all the comforts and even luxuries of life.

Population.

The population of Europe is estimated at 150,000,000 of souls; which is about one-fifth of the whole population of the globe. The Europeans excel both in vigour of body and in energy and activity of mind; and so far has their progress in knowledge and arts raised them above the inhabitants of the other divisions, that they almost seem to be a superior race. There can be no doubt that in Asia were the primeval seats of the human race, from whence they diffused themselves over the rest of the world. The time and circumstances of their first migrations into Europe, history has not with certainty recorded. The most ancient population of this quarter of the earth which we can trace, consisted of the Celts in the west and south; the Fins in the north-east; and the Laplanders, a diminutive race like the Semoids of Asia, in the furthest north. These ancient inhabitants, who seem to have been thinly scattered, were driven towards the west and north by the Scyrians or Goths from Asia, whose descendants occupy the greater part of Europe; and by the Sarmatians or Slavonic tribes, also from Asia, the ancestors of the Russians, Poles, &c. From Africa, also, a colony of the Iberi passed into Spain at a very early period; and at a later period, the accession of the Hungarians and Turks took place from Asia.

The Irruptions of these barbarous nations who overran the Roman empire, and settled themselves in every quarter of Europe, gave rise to a new and singular state of society, distinguished by the name of the Feudal System. As these conquerors of Europe had their acquisitions to maintain, not only against each of the ancient inhabitants as they had spared, but also against the more formidable inroads of new invaders, self-defence was their chief care, and seems to have been the chief object of their first institutions and policy. With this view, every soldier, upon receiving a portion of the lands which were divided, bound himself to appear in arms against the enemies of the community. This tenure, by which they held their land, amongst a warlike people, was reckoned both easy and honourable. The king or general who led them to conquest continuing still to be their head, had, of course, the largest portion allotted to him. These lands he parcelled out amongst his adherents, binding those on whom they were bestowed to resort to his standard when required, with a number of men proportioned to the extent of territory they received. His chief officers imitated the example of their sovereign, and in distributing portions of land to their dependants, annexed the same conditions to their grant. Thus a feudal kingdom resembled a military establishment rather than a civil institution. The victorious army, cantonned out in the country which it had conquered, continued arranged under its proper officers, who were ordered to hold themselves in readiness to assemble whenever occasion should require their united operations. The names of a soldier and a freeman were synonymous. Every proprietor, girt with a sword, was ready to march at the summons of his superior, and to take the field against the common enemy. Such is the origin and outline of that celebrated system which for many centuries prevailed throughout the whole of Europe. Though it seems well calculated for repelling foreign assaults, yet it was ill fitted to promote the ends of internal order and tranquillity, and was unfavourable to the cultivation of every art but that of war. By the gradual operation of various causes, this barbarous structure has been overthrown in most of the states of Europe. In some countries, however, considerable remains of it are still to be found, and in all its former existence, may be traced in their laws, policy, and institutions.

In Europe, almost alone, or in its colonies, are liberty and free government to be found. In various states, freedom is established beyond the reach of accident or caprice; and when those governments, which in theory are more arbitrary or altogether absolute, the diffusion of knowledge, the state of European society and manners, and the force of public opinion, has rendered in practice comparatively mild, and attentive to justice and the rights of the subject: The universal hatred and detestation of which, in this quarter of the world, where the principles of freedom and of government are so much better understood, they inva-
riably render their authors the objects, in a great measure check such wanton exertions of tyranny as occur under Oriental despotisms. The operation of these causes is extended, and the administration of its different governments in some degree assimilated, by that close and intimate union subsisting amongst various states, which is peculiar to modern Europe. In ancient times, and in other divisions of the globe, every independent state is unconnected and detached. It looks on an inactive spectator, while one of its neighbours is overrunning and conquering another, and interferes not, unless for the defence or extension of its own territorries or dominion. In this state of things, some one individual power is always the ascendant, and ascendency and ascendancy fatal to the independence of the rest; and the face of the political world is perpetually undergoing great and sudden changes. But the similarity in the situation of the European powers; the resemblance of their languages, manners, and laws; the extension of their intercourse by travelling and foreign residence; their union, by the relations of scientific and commercial pursuits, the universality of the Christian religion, and a conviction of the great and common advantages of such an union,—have given birth to an intimate connection in times of peace, and a common feeling of interest in maintaining the existence of the present state of affairs. They form a united whole within themselves, almost separated from the rest of the world,—a great federacy, acknowledging indeed no common chief, but united by certain common principles, and obeying one system of international law. Each power views with solicitude the dangers which beset the rest, and feels itself attacked when any of the weaker states are exposed to the insults or oppressions of their more formidable neighbours. The power that would encroach on the territories of any one feeble neighbour, must lay its account with preserving the usurpation, by exposing its whole dominions and colonies to the combined attacks of the other states, who will immediately unite to restore the former balance of power.

Such is the system of political equilibrium which exists in this quarter of the globe, though an impolitic ambition, or thoughtless security, has frequently prevented its full application to the affairs of modern Europe. We may easily perceive, however, how great has been its influence in maintaining the independence of the different states, if we consider the trifling extent of the changes which have taken place in the relative situations of the European powers, and the distribution of the Continent under separate governments during the long period of modern history. Thus in Europe has been formed a species of general law, which, in most instances, are opposed to the insults or oppressions of their more formidable neighbours by rendering such an appeal fatal to any power that may infringe upon the code; by sending the forces of the rest invariably against each delinquent; by agreeing that any project of violating a neighbour's integrity shall be prevented or avenged, not according to the resources of their neighbour, but according to the full resources of every other member of the European community, and by constantly watching over the state of public affairs, even in profound peace. Such is the balancing system carried to its full extent; and such is the state of refinement to which it is constantly tending.

The time, it is probable, is approaching, when the affairs of Europe, like those of a great commonwealth, shall be settled, not in the field of battle, but in a general congress of deputies from its various states; and any of its nations waging war be regarded as guilty of rebellion; to quell which, all the rest are bound to contribute their aid. But as civil wars will often take place, and sometimes succeed in overturning the governments which they attack, so commotions will also take place in the European community, and may even be of such a nature and strength, as to endanger or even altogether overturn the general confederacy. Of this kind were the late dreadful and alarming convulsions which for a time completely suspended, and seemed to have destroyed, the balance of power in this part of the world. But its different kingdoms having again subsided into their ancient state, after some of the severest agitations to which they can ever be exposed, has established this system much more firmly than if it had never been interrupted; and shown, that no power need hereafter attempt to disturb it, who is not able to subjugate Europe.

The Christian is the universal religion of Europe. Religious with the exception of Turkey, in which Mahometanism is established, but where, nevertheless, at least one half of the inhabitants are Christians. And its religion must be regarded as one of the causes of the superiority of Europe; for wherever the religion of Jesus has penetrated, knowledge, industry, and civilization, have followed. The southern parts of Europe were converted to the Christian faith at an early period. Among the barbarous tribes of the North, the progress was slow. Scandinavia remained Pagan till the eleventh century; some Slavonic tribes on the South of the Baltic till the thirteenth; and it is not above a century since the Laplanders were converted by missionaries from Denmark. The chief divisions of the Christian church are three: The Greek Church, which prevails in Europe, and the two grand distinctions of Catholics and Protestants; the former of which are prevalent in the South, and the latter in the North of Europe.

The progressive geography of Europe will be more properly and more minutely illustrated under the descriptions of its different kingdoms and states. Spain, France, and Britain, were early and fully explored by the Romans, who overran them with their arms, and established in them permanent settlements. Their ships explored the southern shores of the Baltic, as far as the river Rujo, or the Western Dvina, and discovered the names of several tribes along the coasts; they were also acquainted with the southern parts on the left of the Danube, but of the central parts of Germany it is evident, from the maps of Ptolemy, they had no just ideas. Of Scandinavia, the ancients knew only the southern parts, as far as the lakes Wettenau. The Carpathian or Sarmatian mountains were well known, but the line of 50° or 52° north latitude bounded the ancient knowledge in the northeast, and the wide extent of the Russian empire continued almost unknown to Europe until the sixteenth century. The greater and more splendid efforts, indeed, for extending geographical knowledge, have been directed to distant regions; but great and laudable exertions have also been made to improve the geography of European nations. Some of them have already been most minutely and elaborately described; and it is probable, from the great and increasing intercourse amongst its different states, as well as the labours of scientific and public spirited individuals, every fact of importance in the geography of Europe will speedily be unfolded. (1)
EUSEBIUS, surnamed Pamphilus, was born in Palestine, and probably in the city of Caesarea, about the year 270. There is no certain account of his parents or other relations, nor of his early instructors; only he himself mentions, that he received his education in his native country. He appears to have been ordained presbyter by Agapius, Bishop of Caesarea, where he taught a public school with much reputation. In this situation he contracted an intimate friendship with Pamphilus, an eminent presbyter of that church, from whom it is supposed to have derived much assistance in his studies, and from regard to whose memory he is said to have taken the surname of Pamphilus. During the Diocletian persecution, when Pamphilus was imprisoned in the year 307, Eusebius assiduously attended him during his confinement; and after his friend had suffered martyrdom, A.D. 309, he removed to Tyre, where he witnessed other striking instances of unshaken suffering in the cause of Christianity. He next went into Egypt, where the same persecution was carried on, and where he himself was imprisoned, but was afterwards released without having been subjected to any penalty; a circumstance which, without any apparent ground, brought upon him the charge of having made some dishonourable submission to the enemies of his faith. When the persecution ceased, he returned to Palestine, and was elected Bishop of Caesarea as is generally supposed in the year 315; but, at all events, he filled that see in the year 320. From this period, he was present at most of the synods held in that part of the world; and was generally the advocate of mild and forbearing measures. He was one of those bishops who conceived that Arius had been severely treated by Alexander, Bishop of Alexandria, to whom he wrote a letter in his behalf. He acted a distinguished part at the celebrated Council of Nice in 325, in which, by the command of Constantine, he was placed on the right of the throne, and opened the proceedings by an address to that Emperor. He hesitated long to admit the term incarnate, consubstantial, on the ground that it was unscriptural; but afterwards concurred, upon condition of being allowed to subscribe it in his own sense of it, namely, "that the Son of God was not like created beings, but received his existence and his perfections from the Father in a different and in an ineffable manner." Hence it has been keenly contested, whether he favoured the sentiments of Arius or of Athanasius. The most likely opinion is, that he assented to neither, but endeavoured to steer a middle course, which has rendered him obnoxious to the more violent disciples of both. In the year 330, he concurred with the council at Antioch in deposing Eustathius, Bishop of that city; but, though he was elected to the vacant see, which was more honourable and profitable than that of Caesarea, and though he was earnestly urged by the bishops and people to accept of the succession, he persisted in his refusal. In 335, he was present at the Council of Tyre, where he joined those bishops who condemned the proceedings of Athanasius, Bishop of Alexandria; and having been deputed to justify the sentence to Constantine, he pronounced his celebrated panegyric of that emperor during the public rejoicings, in the 30th year of his reign. He was honoured with very particular marks of the emperor’s favour, being often invited to his table, and admitted to his private conferences; and, after his return to Caesarea, received from him many letters, several of which he has inserted in his life of that prince. It does not, however, app
books, which is generally counted rather a panegyric than a history, and in one passage of which the author goes so far as to compare the three sons of that emperor to the Trinity; a Commentary upon the Psalms; a Commentary upon the Prophecies of Isaiah; the Evangelical Preparation, in fifteen books; and the Evangelical Demonstration, originally in twenty books, but of which the last ten are lost; two works which contain the most learned defense of Christianity, both against Jews and Pagans, that has been transmitted from ancient times. The argument proceeds upon the opinion, that the ancient philosophers had received many truths, either immediately or by tradition, from divine revelation. Among the materials collected in illustration of this point, there are preserved many fragments of writings which had been long lost. Of these two works, a beautiful edition was printed in Greek by Robert Stephens in 1544, in two volumes folio; which were reprinted at Paris in 1628, in two volumes folio, with a Latin version of the former by Francis Vigerus, and of the latter by Donatus. The Evangelical or Ecclesiastical History, in ten books, which contains the history of the church from the birth of Christ to the death of the elder Licinius, a period of 324 years. This is accounted the most valuable, but the least accurate, of all the larger works of Eusebius; yet, with all its defects, it is a most important production, as furnishing the principal information which we possess concerning the first ages of Christianity, and the books of scripture then received as inspired writings. Of this work, the edition princeps, translated into Latin by Ruffinus, was printed at Utrecht 1476; but the best edition is that of Henry Valesius, who carefully revised the Greek text, and gave a new translation, with many learned notes, printed at Paris in 1671, at Frankfort in 1672, and at Cambridge in 1729, in three volumes folio, by William Reading, who has added to the notes of Valesius several observations collected from modern authors, but which Le Clerc pronounces to be of a very inferior character. See Valesius' Life of Eusebius, prefixed to the Eccles. Hist. Le Clerc Life of Eusebius. Le Clerc's Ars Crit. vol. iii. Fabricius, Bib. Grav. v. 30. Du Pin, Bib. t. ii. 1. Beaussobre, Hist. i. 345. Fleury, Hist. Eccles. vii. Bassigny, Ann. ii. 753. Tillemont, Euseb. ev. Mem. t. vii. Cave's II. L. vol. i. in Euseb. Jortin's Remarks on Ecc. Hist. vol. ii. p. 91. Lardner's Works, iv. p. 201. 'New Bishopric of Mosheim. Eccles. Hist.' vol. i. p. 357. Breucker's Hist. of Phil. by Enfield, vol. ii. p. 308. (a) EUSTATIA, St. is the name of one of the leeward Carribee Isles, belonging to the Dutch. It is about 29 miles in circumference, and consists of two mountains forming a huge pyramidal rock rising out of the sea. The pyramid terminates in a plain encircled with woods, and has a hollow in the middle, which serves as a den for wild beasts. There is only one landing place in the island, which is of itself difficult of access, and is besides fortified with great skill. Although there are neither springs nor rivers in the island, yet the sides of the mountains are laid out in neat cultivated settlements. The pyramid is cultivated even to the top, and sugar and tobacco are produced in considerable quantities. Hogs, kids, rabbits, and all kinds of poultry, are reared in such abundance, that the inhabitants even supply some of the neighbouring islands.

The property of the island of St Eustatia was first granted by the states-general to some merchants of Flushing. It was settled in 1600, and was taken by an English armament from Jamaica in 1665. It was afterwards taken in the time of Louis XIV., by the combined Dutch and French; and the French king at the treaty of Breda, retained possession of it in spite of the remonstrances of his Dutch allies. As soon as the treaty, however, was signed, he restored the island of his own accord to the Dutch. The French drove the Dutch from the island soon after the revolution in 1788; but they were expelled from it in their turn by the English under Sir Timothy Thornhill, who left a small garrison for its defence. The Dutch obtained entire possession of it at the treaty of Ryswick. Admiral Rodney got possession of the island in 1781. The French under the Marquis de Bouillé retook it before the close of the year, and it was finally restored to the Dutch at the peace of 1783. Population 5000 whites, and 15,000 Negroes. The position of the road according to astronomical observations, is in West Long. 63° 44' 45", and in North Lat. 17° 29". (d) EUTOSTHENE: Genera, in Music, according to Dr Wallis' opinions of the various scales which the Greeks pretended to have in use, consisted of the following modes of dividing the tetrachord, or minor fourth, viz.

Two of them involving higher primes than 5, all of which are excluded in modern music without temperament, which to the Greeks was unknown it is believed. (a) EUXINE SEA. See BLACK SEA. EX. See Devonshire, Vol. VII. p. 869, col. 2. EXCENTRICITY. See Astronomy Index. EXCESSIVE, in Music, in the nomenclature which we wish to recommend of musical intervals, is applied (as the opposite of Defective, which see) to intervals that are enlarged beyond their regular quantity, by any other interval than the major comma C (redondant), the minor semitone G (superfluous), the minor or medius semitone C  or C (sharpened), the minor, medius, or major semitone G, G, or G (greater or major). Our readers will accordingly meet on different occasions with schisma-excessive (?), minor comma-excessive (I), diaschisma-excessive (o), enharmonic diesis-excessive (o), subminim semitone-excessive (?), minimum semitone-excessive (?), apotome-excessive (P), &c. as the prefixes to the names of different intervals. (a) EXCHANGE, in commerce, has two significations, the one expressive of a place of public resort among merchants on particular days, or rather at particular hours of every day of business; while another and a more important meaning of the word denotes the payment or receipt of money in one country for its equivalent in the money of another country, by means of bills of exchange.

I. In the former meaning of the word, the exchanges of Amsterdam and London have long been famous throughout Europe. Large as is the crowd collected daily between the hours of two and four at the latter, the assemblage of the Amsterdam exchange is said, in the days of the mercantile prosperity of the Dutch, to have been considerably more numerous; an assertion, however, which should be qualified by admitting that traders of an inferior description were accustomed to repair thither. In point of extent of space, the new

21
Exchange. An allowance of interest for 30, 40, or 45 days, is granted in consideration of the superior value of money in the metropolis; and no farther difference exists, as the currency of the two cities is uniform. A striking example of this tendency of exchange to approach to a state of equality. In the same manner, two countries trading with each other, though necessarily subject to somewhat greater fluctuations than two provinces of the same empire, discover, in fact, much more of apparent than real difference in the point of exchange. The object of all trade is to exchange the commodities of one place for those of another; and merchants have no interest in creating in any place an inequality in the value of money. Equality of imports and exports leads to corresponding equality of debts and credits, and money being thus of the same value in one place as in another, the course of exchange is consequently at par. It is not infrequent for circumstances to occur which tend to upset this the natural state of things. A deficient crop in one country, leads to an importation of corn beyond the amount which can conveniently be balanced by exported commodities; and the result is, a balance in favour of the country which has sold the corn. In that country, money becomes of somewhat more value than in the debtor country, because the object of the latter is to get it conveyed thither, in order either to procure further supplies, or to discharge the debt which has been incurred. Specie is accordingly sent thither, as soon as the difference of value in the two countries becomes such as to defray the cost of its transport. As it lies in very small compass, the chief expense of its transportation by sea is its insurance, the rate of which is, in time of war, necessarily affected by the hazard of capture. In some cases, though very rarely, the edicts prohibiting intercourse and interchange of specie, create an additional burden on the traffic. Such prohibitions are so inefficient, and so unnecessary, that we should not have adverted to them, had not the experience of the present age shown, that there still exist governments so backward as to lay stress on them as a part of its code of regulations.

The stock of coin in a particular country, being no more than is requisite for the transactions of current business, it seldom happens that much of it can be sent abroad. Bullion is therefore the more frequent resource; and the want of bullion leads naturally to the purchase of it from countries such as Spain, or Spanish America, where it forms a principal article of export. During our late years of pecuniary distress, we have imported, in surprising quantities, the metallic treasures of the Spanish Main; but their possession has been very transient, the military contest in the peninsula, and afterwards in the north of Europe, having operated as immediate and complete absorbents. India even has been made to furnish supplies of gold and silver, the latter probably for the first time, as she has been making annual drains of silver from Europe and America during several centuries. Like the specie of the West, the imports from India found a speedy vent on the continent, and paper has continued the only currency of this country. Until the late stoppage of neutral trade, a British commissary on a foreign station was accustomed to apply for specie, not to government at home, but to the merchant, generally American, who imported the chief supply of goods into the place of his residence. He gave the American a bill on London, and received in return the current money which the latter had obtained for the sale of his
EXCHANGE.

The American remitted his London bill to a mercantile correspondent, like Messrs Barings, who paid it away, by order of the owner, to persons exporting manufactures to the United States. The result accordingly was, that the manufacturers in Yorkshire or Lancashire were actually the contributors of the funds required for our continental expenditure, whether the latter were wanted in the Mediterranean, the Baltic, or the central part of Europe.

Were governments to avoid expensive foreign armaments, the course of exchange would experience comparatively little fluctuation. In itself, it has a steady tendency to approximate to a level; for no sooner does money become of more value in one country than another, than it is the interest of the merchant to send goods to the spot in question. Intelligence of the relative prices of commodities is transmitted from country to country by every post, and no men are more expert in making shipments, whenever a rise of price affords a tolerable chance of advantage. These shipments are continued until prices are brought to a level, a circumstance which can hardly happen until the exchange has been equalized. Any species of merchandise may thus be made instrumental in contributing to bring things to the desired level. Bullion has, moreover, the advantage of general currency, and is consequently resorted to as the readiest instrument for smoothing the inequalities of exchange. Being saleable everywhere, and subject to no loss by retention, except the loss of interest, it is particularly calculated for the purpose in question, so soon as the difference of exchange between two countries becomes such as to pay for its transmission. The exportation of it takes place either in bars, as in American districts, or in metallic pieces formed out of coin melted down for the purpose of concealment. Almost all governments have been desirous of prohibiting the export of their current coin, and all have been unsuccessful in the attempt. The process of melting is too short and too easy to be restrained by law; so that the chief result of the prohibitory edicts has been an enhancement of the value of the transmutated metal in proportion to the risk incurred in the evasion. This process, however, is unnecessary in this country, in regard to foreign coin, Spanish dollars for example, which being exempt from restriction in point of export, often form a large part of the specie sent abroad for mercantile and political purposes. Our laws do not aim at keeping all kinds of coin within the limits of the kingdom; they are directed only to the retention of our own currency.

Nominal exchange. We are now to leave the consideration of the actual effects of trade, and to direct our attention to the distinctions created by artificial differences in the value of currencies. It is common to speak of a par of exchange between two countries, by which is meant "that sum in the currency of either, which contains the same value of gold or silver as a given sum of the currency of the other." In former years eleven guilders of Holland were equal to a pound sterling, and whenever our pound was above or below that standard in Dutch money, the exchange with Holland was accounted so much above or below par.

Differences in exchange frequently exist without much real inequality in the value of specie between the one place and the other, and these are commonly called nominal. In times when civilization had made less progress, and the true policy of countries was little understood, it was not uncommon for the sovereign to debase the quality of the coin. A more recent, and some-
the year 1796, no paper currency of consequence in that empire. The other nations of the Continent being somewhat less credulous, and their governments less violent than the French, have dealt in more gradual issues, and have continued, to a considerable degree, the use of the degraded currency. Its effect on the state of exchange will be seen in a moment, on comparing the rates now quoted for bills on Russia, Austria, or Sweden, with the rates of former years, when the computations were made exclusively in coin. In our own case, there can remain little doubt that the fall of our exchange relatively to France, Holland, America, and other quarters where the currency is sound, has been the consequence of the non-convertibility of our paper currency. The depression has continued too long to be accounted for by temporary causes. Not that over issues of bank notes produced the fall in the first instance, but the fall once occasioned by the operation of mercantile and political causes, our specie, as we explained under the head of Bullion, was sent abroad, and the substitution of paper at home was the cause of preventing its return. This paper, however undoubted in point of character, is not current on the Continent; it is not convertible into specie, and therefore undergoes a considerable fall, when exchanged for the precious metals. On attending to the fluctuations in this respect, we find that our paper has regularly fallen in proportion as demands for subsidies or other purposes increased the sum required on the Continent.

Computed exchange.—After describing the exchange, both in its real and nominal character, the subject may appear to be exhausted; but there remains a third discrimination, known by the name of computed exchange. This might be better understood, if it were called the apparent or current rate of exchange, for it means nothing else than the rates as they are quoted in the mercantile letters of the day. Merchants take no account of the causes which operate more or less remotely on the statements of exchange. Their business is with its actual condition; a condition which may be affected by circumstances connected with either the real or the nominal exchange. A sudden demand of corn from the Baltic, may make the real exchange between England and Poland in favour of the latter; while the depreciated paper of Poland, at least of Russian Poland, may produce a calculation apparently favourable to England. This calculation forms, as it stands, the computed or current exchange, and is the only part of the matter noticed in the letters, or attended to in the speculations of merchants.

In describing the nature and effect of inequalities in exchange, a very important question is, whether they are, or are not, productive of actual loss? Some persons imagine that a nominal fall in the value of currency, leaves things nearly as they were, but we have only to analyse the transactions of our own governments with foreign countries, since 1808, to be satisfied that the loss is real and absolute. Our taxes are paid in paper, while a considerable portion of our expenditure must be defrayed in specie. That specie must either be bought up by government at a great loss, or our commissaries in foreign parts must sell bills on the Treasury at a discount which, of late years, has risen from 10 and 15, to 20, 25, and even 30 per cent. The addition thus made to our public expenditure is serious, while, on the other hand, the fall of money has no tendency to produce a counteracting increase of revenue, except in that limited portion of our taxes which are levied on merchandise or property ad valorem. In the reign of William III, a similar inequality existed, our exchange with Holland being 25 per cent. below par. This being prior to our adoption of paper currency, was caused by the reduced weight of our silver coin; for at that time, and for 20 years after, silver constituted our money-standard. Our coinage was reformed at a very heavy expence, in the reign of William; and the exchange recovered its level in the same way that it recovered from the comparatively small depression which existed previously to the recoining of 1774. In Holland, long as she has been a commercial country, the currency has been confined to specie, and more particularly to silver. In the cities, indeed, all great transactions are discharged in cheques; but bank-notes, payable, on our plan, to the bearer, are unknown. Gold ducats are sometimes used, but the major part of cash payments is made in dollars.

Merchandise Calculations of Exchange.

The principal trading cities in Europe use the monies of exchange explained in the following Tables.

Hamburg.

Exchanges are computed in marks, schilling lbs., and penceings; or in pounds, shillings, and pence Flemish; also in rixdollars, marks, &c.

12 Pfennings = 1 Schilling lbus.
16 Schillings = 1 Mark.
3 Marks = 1 Rixdollar.
6 Pfennings = 1 Grote or penny Flemish.
12 Grote = 1 Schilling Flemish.
20 Schillings Flemish = 1 Pound Flemish.
Thus, 6 Schilling lbs. = 1 Schilling Flemish.

7½ Marks = 1 Pound Flemish.

There are two sorts of money in Hamburg, called bane and currency. Banco bears an agio, or premium against currency, which is generally from 20 to 25 per cent.

Amsterdam.

Exchanges are computed in florins, stivers, and penceings; or in pounds, shillings, and pence Flemish.

16 Pennings = 1 Stiver
20 Stivers = 1 Florin or Guilder.
2 Grotes, or
Pence Flemish = 1 Stiver.
12 Grotes or 6 Stivers = 1 Shilling Flemish.
20 Shillings Flemish, or 6 Florins = 1 Pound Flemish.

There are two sorts of money in Holland; namely bank-money and currency; bank-money generally bears a premium of 2, 3, or 4 per cent. which is called agio.

Paris.

Exchanges are computed in francs and centimes; or in livres, sous, and deniers tournois.

100 Centimes = 1 Franc.
12 Deniers = 1 Sou or Sol.
20 Sous = 1 Livre.
80 Francs = 81 Livres.
3 Livres or 3 Francs = 1 Ecu of Exchange.

America.

Exchanges are computed in dollars, dimes, and cents; and in some places in pounds, shillings, and pence currency.
In the days of the prosperity of Holland, Amsterdam was the great medium of European exchange. Its central situation, the magnitude of its commerce, and the well known accuracy of Dutch merchants, rendered it a kind of pivot, on which the various exchanges of other countries had a regular tendency to turn. The effect of this convenient and central point was to create a steady inclination towards equality in the bill-transactions of different countries. If it happened that a sudden export of merchandise from one kingdom to another, created an irregularity in the exchange, the medium of Amsterdam was open to modify the extent of the difference, by putting into the balance the bills arising from the transactions of the countries in question with other parts of the world. This complicated question will be best understood, by bestowing attention on the exchange operation commonly known by the name of the "chain rule," or "arbitration of exchanges." This curious and ingenius method proceeds on the principle of lessening the inequality of a direct interchange of bills between any two cities or countries, by adopting a comprehensive and circuitous course. We extract the following explanation from Kelly's Cambist, a work of merit on the subject of which we are treating.

In 1804, Spain was bound to pay to France a large subsidy; and, in order to do this, three direct methods presented themselves:
1. To send dollars to Paris by land.
2. To remit bills of exchange directly to Paris.
3. To authorize Paris to draw directly on Spain.

The first of these methods was tried, but it was found too slow and expensive; and the second and third plans were considered as likely to turn the exchange against Spain. The following method, by circular exchange, was therefore adopted.

A merchant at Paris was appointed to manage the operation, which he thus conducted: He chose London, Amsterdam, Hamburg, Cadiz, Madrid, and Paris, as the principal hinges on which the operation was to turn, and he engaged correspondents in each of those cities to support the circulation. Madrid and Cadiz were the places in Spain from which remittances were to be made, and dollars, of course, were to be sent where they bore the highest price, for which bills were to be procured on Paris, or on any other places that might be deemed more advantageous.

The principle being thus established, it only remained to regulate the extent of the operation, so as not to issue too much paper on Spain, and to give the circulation in each branch as possible from real business. With this view London was chosen as a place to which the operation might be safely directed, as the price of dollars was then high in England: a circumstance which rendered the proportional exchange advantageous to Spain.

The business was commenced at Paris, where the negotiation of drafts issued on Hamburgh and Amsterdam served to answer the immediate demands of the state; and orders were transmitted to those places to draw for their reimbursements on London, Madrid, or Cadiz, according as the courses of exchange were most favourable. The proceedings were all conducted with judgment, and attended with considerable success.

The particular mode of calculation will be under-

stood with little difficulty, from the following example.

Suppose £1000 sterling is to be remitted to Cadiz, and the direct exchange is 40d. sterling per dollar, but the remitter wishes to send it through Holland and France; it is required to know which is the most advantageous, the direct or indirect remittance, the quotation of the course of exchange being as follows?

London on Amsterdam, 35 shillings or shillings Flemish per pound sterling. Amsterdam on Paris, 60 pence Flemish for the eon of 3 francs. Paris on Cadiz, 15 francs for 1 doubloon of 4 dollars of exchange.

Statement.

\[ \begin{align*}
1 \text{ Pound sterling} & = 35 \text{ Shillings Flemish.} \\
1 \text{ Shilling Flemish} & = 12 \text{ Pence Flemish.} \\
60 \text{ Pence Flemish} & = 3 \text{ Francs.} \\
15 \text{ Francs} & = 1 \text{ Doubloon.} \\
1 \text{ Doubloon} & = 4 \text{ Dollars.}
\end{align*} \]

Hence

\[ 1000 \times 35 \times 12 \times 5 \times 4 = 50400 \]

\[ 60 \times 15 \]

\[ 9 \]

The perplexity produced by the endless variety of money denominations in different countries, has long been a subject of general regret. Like the equalization of weights and measures, it has at different times engaged the speculations of philosophers, and sometimes the attention of governments. The American plan of reckoning by tenths and hundredths of a dollar, is accounted a considerable step towards simplicity, and has been followed in some measure by the French government. At the beginning of the French revolution, the views of the enlightened men who belonged to the Assemblee Constituante, were directed to the establishment of an universal standard for the regulation of weight and measure. The consequence has been the introduction of new denominations in both respects; but so slow are changes of this description, that the old method is still preferred throughout the chief part of France. In the adjoining countries, the new plan has not found, as far as we know, any imitators. Among ourselves, an equalization of weights and measures has been repeatedly talked of; but no investigation from authority has taken place since the year 1758, at which time a committee of the House of Commons was appointed, to make a report on the subject. Without venturing to go into the field of general disquisition, this committee put on record a very clear and accurate exhibition of the present state of our weights and measures; and ascertained, that the standard avoirdupois pound kept in the Mint weighed exactly 7000 grains troy, a weight strictly corresponding to that of the two other avoirdupois standards preserved for successive ages at the Exchequer and Guildhall. (Oj.)

EXCHEQUER. (excaecarium, from the French Echiquier, or the German Schatzkammer, Treasury), is a very ancient court of record, wherein the king's revenues are received, and all causes respecting the revenue and rights of the crown are heard and determined.

Camden says that this court took its name from the table at which they sat, the cloth which covered it being party-coloured, or chequered. (Brit. p. 113.) Some persons have thought that there was an exchequer under the Anglo-Saxon kings; but our best historians are of opinion, that we derived this institution from the ancient Norman exchequer, and that it was introduced from thence by William the Conqueror. It
In Exchequer, 30. The act to determine though the occasion given from water E Skinner, a the u deprived cTCCted rf diamber. course, counts lie which upon by arrr, WeewTcr, the Clerk of the Pells; so called from his parchement rolls; the clerk of the Nikils; the clerk of the Pleas, &c.

The Court of Exchequer is inferior in rank to the courts of King's Bench and Common Pleas. It is divided into a court of equity and a court of common law. The court of equity is held in the exchequer chamber, before the Lord Treasurer, the Chancellor of the Exchequer, the Chief Baron, and three puisne Barons, whose original and primary business related to the fiscal rights of the crown. But now, all kinds of personal suits may be prosecuted in the Court of Exchequer, upon the suspense that the plaintiff is debarred to the king, which is held to be mere matter of form and words of course, the truth of which is never controverted. This fiction gives rise to the common law part of the jurisdiction of the Court of Exchequer, which is exercised by the Barons only. The writ, upon which all proceedings here are grounded, is called a quo minus, in which the plaintiff suggests that he is the king's debtor or farmer, and that the defendant hath done him the injury or damage complained of, quo minus sufficiens existit, by which he is the less able to pay the king his debt or rent. In the same manner, also, in the equity side of the court, any person may file a writ against another, upon a bare suggestion that he is the king's accoumtant. In this court, on the equity side, the clergy have long been in use to exhibit their bills for non-payment of tithes; but the Chancery has now obtained a large share of this business. From the equity side of Exchequer, there lies an appeal directly to the House of Peers; but from the common law side, a writ of error must be first brought into the Court of Exchequer Chamber.

The Court of Exchequer Chamber has no original jurisdiction, but is only a court of appeal. It was first erected by statute 31 Edw. III. c. 12, to determine causes upon writs of error from the common law side of the Court of Exchequer. It consists of the Lord Treasurer, the Lord Chancellor, and the Justices of the King's Bench and Common Pleas. A second Court of Exchequer Chamber, in imitation of the former, was erected by statute 27 Eliz. c. 8, consisting of the Justices of the Common Pleas, and the Barons of the Exchequer, before whom writs of error may be brought to reverse judgments in certain suits, originally begun in the Court of King's Bench. Into the Court of Exchequer Chamber, (which then consists of all the judges of the three superior courts, and now and then the Lord Chancellor also,) are sometimes adjourned from the other courts, such causes as the judges, upon argument, find to be of great weight and difficulty, before any judgment is given upon them in the court below. From all the branches of this Court of Exchequer Chamber, a writ of error lies to the House of Peers.

The ancient Court of Exchequer in Scotland, which was the king's revenue court, was, by the treaty of union, (Art. 19.) to continue until a new revenue court should be established by parliament, which was accordingly done by 6 Ann. c. 26. The judges of this court are the High Treasurer of Great Britain, with a Chief Baron, and four other Barons, who must be made either of sergeants at law, or English barristers, or Scottish advocates of five years standing. All may plead before this court who can practice in the courts of Westminister, or in the Court of Session; and all the privileges of the College of Justice, are communicated to the Barons, and to the other members of this court.

The jurisdiction of the Scottish Court of Exchequer extends to all matters regarding the revenues of the crown; but under two limitations, which were intended to preserve the private law of Scotland from innovation. 1st, That no debt due to the crown shall affect the debtor's real estate, in any other manner than such estate might be affected by the law of Scotland; and, 2dly, That the validity of the crown's titles to any honours, lands, or casualties, shall be tried, as formerly, by the Court of Session. See Madox, Hist. of the Exchequer; Blackstone's Comment, b. iii. ch. 4; Jacob's Law Dict. v. Exchequer; and Erskine's Inst. of the Law of Scotland, b. i. tit. 3, § 30. et seq. (2)

Excise, (generally understood to be from the Bellig accise, toll or tribute; though others, as Skinner, derive it from assisa, assize, as being rated by men appointed for that purpose,) a branch of the public revenue, arising from duties paid upon the manufacture or sale of certain commodities made or sold within the kingdom. Excise, in its proper acceptance, applies solely to duties imposed on consumable commodities made or produced at home, in contradistinction both to customs, which are duties payable upon commodities imported from abroad, and to assessed taxes, which are duties imposed upon the use of certain commodities not immediately consumable. From experience, however, of the utility of some of the excise regulations, certain branches of revenue arising from both of these have occasionally been put under the management of the excise, but this was an extension not contemplated at its first establishment.

The origin of excise, as well as other branches of revenue, must be sought for in the unavoidable wants of the state, consequent upon the progress of civilization and extension of commerce. The revenue required to defray the expense of providing either for the internal security or external defence of a state, may be drawn either from some fund belonging to the sovereign and the public, or from a part of the private revenue of the people themselves, levied by means of taxation. In the earlier periods of society, the former mode, appears always to have prevailed, and, in many states, even after the introduction of commerce, public property has been regarded as one of the great sources of revenue; the silver mines of Attica constituted a large part of the public funds of the Athenian republic; and in all the kingdoms of modern Europe, the crown lands were long the chief resource on which the sovereign relied for defray-
ing his expenses. In time, this resource was found to be wholly insufficient, partly from the waste and dilapidation of this public property, but chiefly from the rapid increase of expenditure in the progress of society. To supply the deficiency, taxes were introduced, upon the equitable principle, that the people were bound to contribute a part of their private revenue, to answer the exigencies of the state, incurred for the common safety and benefit of all. Taxes must vary in their nature, according to the situation of the community, and the mode of subsistence. In countries chiefly agricultural, taxes upon land will probably form the principal source of the public income; in commercial states, taxes upon commodities will be found most availling. In taxing commodities, foreign goods imported are generally first selected; the duties payable upon these constitute that branch of revenue denominated *the customs*. As the exigencies of the state increase, taxation is extended to inland manufacture, and inland trade of various descriptions: it is this last branch of revenue which constitutes the *excise*.

It can hardly be doubted, that in every community so far advanced in civilization as to admit an active interchange of commodities and the separation of trades and professions, some species of taxation in the nature of an *excise* will always be produced, so as to be the wants of the sovereign or the state call for any extraordinary supply. That taxes upon inland consumable commodities actually took place in ancient times is evident, though the information we have of the manner in which the public revenues in those periods was levied, is too imperfect to enable us to determine with accuracy upon what commodities the duties were imposed, or under what regulations they were enforced. Among the Greeks and Romans, consumable commodities of most general use appear to have been subjected to various rates; and so far as can be found, these were laid on the sale or transit of the goods, and not, as in many cases in modern times, upon the manufacture. The common mode of levying the duties, was by officers stationed either at the principal ports, at the entrances of towns, or in certain places upon the usual roads; and the practice seems to have been universal, of farming out the different branches of revenue, instead of levying them by the immediate issue of government. In modern times, excise duties appear to have been first, and as the wants of the commercial states. Among these, the extent of territory being considerable, and the circulation of goods frequent and rapid, consumable commodities constituted an obvious, and probably an easier source of revenue than any other. These were therefore resorted to, when large sums for the public service were required. In the Low Countries, and in Holland, duties of this description were first brought to a regular system, and hence probably we have borrowed the name from the Belgics.

In England, though subsidies, aids, and benevolences, were from a remote period granted to the monarch, and though the customs, or duties upon imported goods, took place very early, yet it is generally understood, that what are properly termed *excise* duties, were never levied before the year 1643, when they were introduced by an ordinance of the republican parliament at Westminster. The duties then imposed, were at first chiefly confined to commodities, where it was thought the burthen would be least perceptible; such as beer and ale, cider, percy, and the like. The royalist parliament at Oxford quickly followed the example, by imposing similar duties. In 1644, the excise was extended by the Westminster parliament to butcher meat, wine, tobacco, sugar, and a number of other commodities in general use. The mode of levying the duties imposed by these acts, was more strict than it was afterwards found advisable to continue, not only makers and vendors, but even private persons preparing the commodities for their own use being obliged to account. In 1656, by an ordinance of Cromwell, new excise duties were imposed in room of the former, on beer and ale, cider, percy, wine, oil, and various other articles, which subsisted till the restoration. Upon the return of King Charles in 1669, Cromwell’s ordinance of course fell to the ground; but some part of the excise duties which had been imposed were then re-established, and assigned to the crown as a compensation for the feudal tenures, and other oppressive branches of the prerogative. The commodities subjected to the tax at that time, were beer and ale, cider, percy, mead, vinegar, spirits, coffee, chocolate, sherbet, and tea; the tax attaching only to such as were made for sale, and coffee, chocolate, and tea, being rated by the gallon like strong waters.

These duties (with the exception of what had been rated upon the gallon of coffee, tea, and chocolate) were continued after the Revolution, and made part of the civil list revenue. The duties on spirits were carried to the aggregate fund in 1736; and those on malt liquors in England, were applied to the same fund in 1760. Large additions have from time to time been made to all of them. In 1694, a duty upon salt was established, which was properly an excise duty, though then put under different management. In 1697, malt was subjected to an excise duty, temporary at first, but revived in 1713, and, with large additions, continued to the present time. During the French wars in the reign of Queen Anne, the exigencies of the state calling for new impositions, the articles of sweets, soap, leather, candles, hops, paper, printed goods, starch, gold and silver wire, were all made liable to excise. In 1724, the duties upon tea, coffee, and chocolate, were transferred to the management of the excise. The manufacture of glass had been subjected to excise duty in the reign of King William, but such a tax being deemed prejudicial to an infant manufacture, it was very soon taken off; however, in 1746, excise duties upon glass were again imposed, which, with considerable additions, still subsist. The remaining branches of revenue now under the excise, are the following: Sales by auction, subjected to excise duty in 1777; bricks and tiles in 1784; wine in 1786; tobacco in 1789; salt in 1798; and stone bottles in 1812.

The introduction of the excise into Scotland, appears to have been nearly cotemporary with its establishment in England. Excise duties were first imposed in Scotland in 1644; these were farther regulated and extended in 1645 and 1647. After the Restoration, various duties termed excise, (though more properly customs) were imposed by parliament in 1661, upon wine, vinegar, soap, salt, tobacco, cloth, hats, gloves, and other goods imported; and along with these, a proper excise duty was imposed upon malt made within the kingdom. Brandy and rum imported, were subjected to excise in 1673. Malt liquors and spirits made in Scotland in 1693, the duty upon malt itself being soon after taken off. At the union in 1707, the excise duties then existing in England were extended to the whole united kingdom, the former Scotch excise duties being discontinued. Since that period, the excise duties have, in general, been the same in both parts of the kingdom, with some occasional de-
vations, for the most part in favour of Scotland. The extension of the excise on malt to Scotland in 1718, occasioned much discontent and commotion through the country for several years. At length, in 1785, the Scotch malt duty was fixed at one half of the English. Even with this abatement, the discontent was not allayed for some time, and it required no small degree of exertion and firmness to carry the tax into effect.

The excise duties in other countries, appear so far to resemble those in Great Britain, that the articles which form the subject of this tax are generally similar, allowing for unavoidable differences arising from the mode of living, the necessities of the state, and not unfrequently the ignorance of the rulers. In Holland, besides almost all the articles specified, as falling under the excise in Great Britain, similar duties are imposed on butcher meat, fuel, lead, hardware, &c. In France, the iron manufacture before the revolution was a subject of taxation; and an oppressive duty under the name of gabelle, levied on the consumption of salt. In Spain, cloth manufactured was taxed, and every time it was sold a new duty was incurred.

The general principles of the excise as a mode of taxation, have been already mentioned. It is a duty imposed on the manufacture or sale of commodities within the kingdom. For this purpose, all persons engaged in those branches of manufacture upon which the excise attaches, are required to make an entry of the premises in which the business is carried on; to allow access there to the revenue officers, that an account may be taken of the quantities manufactured; and a corresponding charge of duty made, according to the rates established by law. In several of the taxed articles, the interference of the excise is carried no farther, the subsequent sale and transit of the commodities being free; but in others, particularly where the duties are high, it has been found requisite, for the security of the revenue, to subject also the dealers and sellers of the commodity to the tax to the excise officers, in the places where the goods are kept and sold, and at the same time to prevent their transit, unless accompanied by a certificate, to signify that the duties have been paid. It is on account of these regulations chiefly, that certain imported goods, particularly spirits, wine, tea, and tobacco, have been put under the management of the excise, and it has been found by experience, as Dr Smith justly remarks, that the excise regulations embarrass the operations of the smuggler more effectually than any other: hence, for the security of the revenue, they have been adopted in many articles, although it cannot be denied, that they may give rise to inconvenience and irritation, and are certainly in their nature not strictly agreeable to the free principles of the British constitution. Upon this account they have always been unpopular, and an instance occurred in the time of Sir Robert Walpole, when the prejudice of the nation was so strong against them, that that minister was forced to abandon a projected measure for subjecting wine and tobacco to the excise, although it was then believed, and has since been confirmed by experience, that the revenue would have received material advantage from it. The excise laws and regulations may, however, be vindicated, on the ground, that they are necessary when a large revenue is required for the service of the public; and though they are not free from inconvenience, yet in Great Britain at least, the subject is so guarded by law against any undue exercise of power in the officers, that few instances of real hardship occur. The complaints on that head, often arise from traders, who feel their illicit practices obstructed and prevented by their operation. There is, however, one specific regulation, not indeed peculiar to the excise, but still more common in the customs, which has been often, and with much justice, objected to, that of compelling the trader to return accounts upon oath, of the quantities of his goods subject to duty. The hazard of perjury, and the diminution, if not entire loss of all regard to the sanction of an oath, the inevitable consequence of this regulation, must be far greater evils than can be compensated by any additional security which the revenue can thus obtain. Independent of these objections, the regulations of the excise seem upon the whole to be well calculated for securing the revenue at the least possible expense. The tax generally attaches in that particular stage of the operation, where the difficulty of clandestine operation is considered to be greatest; the duty is found to be levied at less expense than the customs; and, after the tax is paid by the trader, it goes with as much rapidity as can well be attained into the public purse.

The mode of levying of the excise revenues at first was by farming them out;—a mode always odious to the public, frequently oppressive, and certainly of all others the most expensive in the end. That system, though pertinaciously adhered to in France, Spain, and many other countries, as being in fact best suited to an arbitrary government, has been wisely abandoned in Great Britain. The whole management of the excise in this country for more than a century past, has been put under the direction of officers appointed by, and immediately accountable to government. The superintendence is placed in two Boards; one for England, consisting of nine commissioners, of whom two are chairmen; and one for Scotland, consisting of five commissioners, of whom one is chairman. The commissioners are nominated by patent from the crown, and vested with the power of appointing all the inferior officers. The total number of officers employed in 1788, in levying and managing this branch of the revenue, is stated by Sir John Sinclair (History of the Public Revenue, cap. 4.) at 1477 in England, and 627 in Scotland,—a number which has since been increased, though not very greatly, considering the great increase of the sum collected. They now amount probably to about 6000 in all. The duties are charged by officers termed gauders, over whom are placed supervisors. Payment is made to collectors in different places, no one being obliged to travel farther to make his payments than to the next market town. The collectors remit the money to the respective cashier for England or Scotland, and the nett amount is afterwards paid over to the receipt of exchequer.

Whatever objections the excise may be liable to in regard to some of its regulations, it is certain that ever since its establishment it has always been one of the most productive branches of the public revenue.

For the first ten or twelve years after the Restoration, when it was in farm, the amount received by the public was upon an average about £420,000 a year. For the whole period between the Restoration and the Revolution, the average may be reckoned about half a million a year. During the reign of King William, several new duties being imposed, and the country gradually advancing, the excise rose to somewhat above a million annually, the total revenues of England being then under four millions a year. At this period, it appears that the total excise in Scotland, which was then entirely separate from, and independent of, the English excise, amounted as paid into the exchequer to £10,000 a year. In the time of
Queen Anne, new duties were added, and the union of the two kingdoms being effected, a juncture, as well as assimilation of their revenues, took place. The annual average of the excise during that reign, was for England about £2,600,000; for Scotland nearly £61,000. Between 1715 and 1726, the reign of George II, the produce of the excise for Great Britain, including the annual malt, was nearly £2,340,000 a year; for Scotland alone about £74,000. During the reign of George II from 1728 to 1760, a gradual increase still took place in the produce of the excise, the annual average being about £3,000,000 for Great Britain; the produce for Scotland somewhat about £97,000 per annum. In 1759, the year preceding the accession of his present Majesty, the nett excise as paid into the exchequer was £3,887,349; the gross produce for Scotland nearly £89,000. After the peace of 1763, the addition of several new taxes, but still more the advancing state of commerce and improvement, gave a new increase to the excise; so that for the five years between 1771 and 1776, the gross annual average amount for Great Britain was £5,340,000; and the gross annual average for Scotland nearly £140,000. During the last five years of the American war, there was still an increase, and proportionally, nothing greater in Scotland than in England, the average of these five years being for Great Britain £5,642,327, and for Scotland alone nearly £247,000. At the time of the peace of Amiens in 1801, the gross amount for England was £12,507,807, and for Scotland £1,054,428. Since that period the amount has nearly doubled the gross produce in 1807; being for Great Britain about £24,000,000; for Scotland a little above £2,000,000. In 1815, the total for Great Britain was about £24,700,000; for Scotland about £1,945,000. By the latest parliamentary finance statements, the gross produce for the year ending 5th January 1814, was for England £25,171,747: : 0: 11: 6, and for Scotland £1,861,691: 4: 2. The expence of levyng, collecting, and managing this large revenue, amounts to no more than £8,19s. per cent. See Huie's Abridgment of Excise Statutes. Scotch Acts. Blackstone's Commentaries. Smith's Wealth of Nations. Sir John Sinclair's History of the Public Revenue. Hamilton's Enquiry into the Principles of Taxation. Parliamentary Reports and Papers. (2) EXCITATION. See Electricity. EXCOMMUNICATION, in ecclesiastical polity, is the judicial exclusion of offenders from the religious rites and other privileges of the particular community to which they belong. Founded in the natural right which every society possesses to guard its laws and privileges from violation and abuse, by the infliction of salutary discipline, proportioned to the nature of the offences committed against them, it has found a place in one form or another, under every system of religion, whether human or divine. That it has been made an engine for the gratification of private malice and revenge, and been perverted to purposes the most unjustifiable and even diabolical, the history of the world but too lamentably proves; yet this, though unquestionably a contumacy which is sought to inculcate the necessity of prudence as well as impartiality and temperance in the use of it, affords no valid argument against its legitimate exercise.

Under the dispensation of Judaism, the contraction of ceremonial impurity or uncleanness, was attended with an ipso facto excommunication from the more peculiar privileges of religion, which continued unrepealed, till the rites prescribed for restoration to legal purity were duly performed. Besides this, there does not appear to have been any excommunication of special divine appointment, except that which was immediately accompanied with the ultimate punishment of excommunication or death; and from which, of consequence, there was and could be no absolution. In the later ages of the Jewish church, indeed, this species of discipline was systematised by the Rabbins, whose opinions, however, are often so contradictory to each other, that it is next to impossible now to ascertain in what the different kinds of their authorised excommunications consisted. By many writers they have been divided into three classes, viz. Niddce, Charem, and Shannatha, but Selden has satisfactorily shewn, that these three epithets are indiscriminately applied by the Rabbinic authors to every variety of this punishment, though in general the term Charem denotes a severer species of it than the other two. Distinguished into greater and less, both of them might be pronounced on an individual either by a public judge, by a court, by a private person, or even by himself. The least kind, commonly termed, Niddie, i.e. Separation, might be incurred in a vast diversity of ways; but those which are fewer than twenty-four are specified in the Talmuds and other Jewish writings; and of which several relate to moral and religious delinquencies, though others of them are of the most frivolous description. When pronounced by a court, it was preceded by private censure and admonition; after which, if the culprit gave no satisfactory evidence of repentance, the house of judgment, or the assembly of judges, solemnly warned and threatened him, that if he did not reform, he must fall under the sentence of public excommunication. If he still continued obstinate, his name, and the nature of his offence, were proclaimed in the synagogue to which he belonged, on four successive Sabbaths, in order to bring him to a just renee of his guilt; and if this also proved ineffectual, he was then solemnly excommunicated. The sentence, whether pronounced publicly or privately, was in force for thirty days, during which he was interdicted from approaching nearer any person, even his relations, than four cubits; from eating bread or receiving any other food which required greater proximity to other persons than that distance; and from performing the usual ablutions, previous to sitting down to his meals. On his remaining impotent at the close of this period, it might be extended to thirty and even to sixty days longer; after which, if still incorrigible, he was subjected to the greater excommunication. This sentence was required to be pronounced by not fewer than ten persons, or at least in their presence, and with their concurrence; and it excluded those on whom it was inflicted from almost all the advantages of civil society. Of its horrible nature, some idea may be formed by the following extract from one which Buxtorf found in an ancient Hebrew MS.: "Ex sententia Domini Dominorum sit in Anathemate Ploni filius Ploni in uraque domo judicis, Supeororum secl. et Inferorum, in anathemate item Sancorum exclusorum, in anathemate Seraphim et Ophannim, in anathemate de nique toitus Ecclesiae maximi num et minimorum. Sim super ipsum plagae magna et soletes, morti magni et terrae. Domus ejus sit hebdomadum dracoum; caii gnominem facit sicut ejus in nubibus; sit in indignationem iram et eundem descendit; cavea ejus obiectatur feris et serpentibus; letentur super ipsa hostes et adversarii; argentum et aurum ipsius dantis alius; et omnes filii ejus
EXCOMMUNICATION.

Ad ostium inimicorum ipsius sint expositi: super die ejus obitius, sequentiam posteri.—Abscondatur sicet Korah et cæntis ejus; cum terrae et tremore egredatur anima ejus; infamatio Domini occidit eum; strangulatur ut Achitophel in consilio suo; sic lepra Gehazi sit lepra ipsius; neque alia sit resurrectio ranae ejus; in sepultura Israëlis non sit sepulcrum ejus; Alienis deretur uror ejus, et super eam pronuncent se aliis in morte ejus. In hoc anathematæ sit Ploni filius Ploni, et hoc sit hereditas ipsius.” Lexic. Talmud, p. 829. The pronouncing of such sentences was frequently accompanied with the lighting of omer in the synagogue, or court-room; the ringing of bells, the blowing of trumpets, &c. practices to which the church of Rome have since had recourse, in order to give greater solemnity and terrific effect to their anathemas. Persons thus excommunicated were prohibited from carrying on their ordinary employments; could not buy or sell any thing but what was absolutely necessary for the preservation of life; and were not permitted to enter any place of instruction for the purpose of either teaching or being taught. No person was allowed to associate, or to eat or drink with them. They were incapacitated for acting either as judges or as witnesses; for circumcising their sons, and for assisting at the funeral obsequies, even of their nearest relations. The ordinary rites of burial were denied them; their friends were not suffered to mourn for them; and a large stone was left on their graves, or the people, and sometimes the judges, heaped stones on the spot where they were interred, as over Achan and Aban, and the sentence of the lesser excommunication, when inflicted by a private person, might be removed by one public judge, or by three men chosen for the purpose; but to the absolution of those who excommunicated themselves, the sentence of ten persons was necessary. He who had been excommunicated in a dream, (as some imagined they might be) could be loosened from this sentence only by ten men learned in the law and the Talmud. Absolution from the greater excommunication, might be obtained from a single judge, provided he was a doctor of the law; but, in other cases, only from the concurring authority of three judges.—It is somewhat doubtful whether, in any instance, excommunication among the Jews, though pronounced by ecclesiastical judges, involved in it exclusion from the synagogues, or is justly to be regarded as having been more than a civil punishment, till about or after the Christian era; but there can be no doubt whatever, that, subsequently to that period, it was so extended, and became in the strictest sense an ecclesiastical and spiritual maladiction. Without entering at all into the controversy concerning the jus divinum of excommunication under the Christian dispensation, we shall only observe, that the early fathers of the church appear to have justified it, chiefly on the ground of its necessity to the preservation of purity of conduct in their religious communities; and that during the two first centuries at least, it seems to have been exercised with becoming moderation. From Tertullian's apology, we learn, that the crimes which in his time subjected to exclusion from Christian privileges, were murder, idolatry, theft, fraud, lying, blasphemy, adultery, fornication, and the like; and, in Origen's treatise against Cælus, we are informed that such persons were expelled from the communion of the church, and lamented as lost and dead unto God, (ut perditus Deoque mortuus); but that on making profession, and giving evidence of penitence, they were received back as restored to life. It was at the same time specially ordained, that no such delinquent, however suitably qualified in other respects, could be afterwards admitted to any ecclesiastical office. Nor does it appear that the infliction of this discipline was accompanied with any of those forms of excommunication, of delivering over to Satan, or of solemn execration, which were usual among the Jews, and subsequently introduced into them by the Romish church. The authors and followers of heretical opinions which had been condemned by the judgment of the Episcopal order, were also subjected to this penalty: and it was sometimes inflicted on whole congregations when they were judged to have departed from the faith. In this latter case, however, the sentence seldom went farther than the interdiction of correspondence with these churches, or of spiritual communication between their respective pastors. To the same exclusion from religious privileges, those unhappy persons were doomed, who, whether from choice or from compulsion, had polluted themselves, after their baptism, by any act of idolatrous worship; and the penance enjoined on such persons, before they could be restored to communion, was often peculiarly severe. The consequences of excommunication, even then, were of a temporal as well as a spiritual nature. The person against whom it was pronounced, was denied all share in the oblations of his brethren; the ties both of religious and of private friendship were dissolved; he found himself an object of abhorrence to those whom he most esteemed, and by whom he had been most tenderly beloved; and, as far as expulsion from a society held in universal veneration, he could impute on his character a mark of disgrace, he was shunned or suspected by the generality of mankind.

It was not, however, till churchmen began to unite temporal with spiritual power, that any penal effects of a civil kind became consequent on their sentences of excommunication; and that this ghastly artillery was not less frequently employed for the purposes of lawless ambition and ecclesiastical domination, than for the just punishment of impudent delinquents, and the general edification of the faithful. But as soon as this union took place, and in exact proportion to the degree in which the papal system rose to its predominance over the civil rights as well as the consciences of men, the list of offences which subjected their perpetrators to excommunication, was multiplied; and the severity of its infictions, with their penal effects, increased in the same ratio. The slightest injury; or even insult, sustained by an ecclesiastical, was deemed a sufficient cause for the promulgation of an anathema. Whole families, and even provinces, were prohibited from engaging in any religious exercise, and cursed with the most tremendous denunciations of divine vengeance. Nor were kings and emperors secure against these thunders of the church; their subjects were, on many occasions, declared, by a papal bull, to be absolved from allegiance to them; and all who should dare to support them, menaced with a similar judgment. Nay, such an extravagant length was this exercise of power carried, that instances are on record of bishops having issued formal excommunications against rats, mice, and even caterpillars, after a regular judicial process against them, in which they were allowed the benefit of an advocate and proctor, to plead and defend their cause. The pronouncing of sentence was accompanied with the lighting of torches, which were then thrown on the ground, and trampled under foot by the people, who beat time to solemn peals rung on the bells. Hence
the old English expression, to curse with bell, book, and candle. The formula was then read to the congregation, and was of the following import: "M. et N. in nomine Patris et Filii, et Spiritus Sancti, et benedictae nostrae Domine Sanctissime Marie, atque virtute angelorum, archangelorumque, &c. sancta matris Ecclesiae gremio segregamus, ac perpetue maledictiones anathematis condemnamus. Sintque maledicti in civitate, maledicti in agro, maledictum horeum eorum, et maledicta reliquiae eorum, maledictus fructus ventris eorum, et fructus terrae illorum. Maledicti sint ingrediéntes, et ingredientes. Sintque in domo maledicti, in agro profugi; veniantque super eos omnes like maledictiones quas Dominus per Mosen in populum diviné legis prævaricatorem se esse missurum intentavit; sintque Athanatha Maranatha, id est, perænt in secondo adventu Domini. Nullus eis Christianus Ave dieat. Nullus Presbyter Missam cum eis celebrare praesumat, vel sanctum Communionem dare. Sexpultura assìx septianteur, et in sterquilinium sint super faciem terrae. Et sicut haec lucerna de manibus nostris projectae hodie extinguuntur, sic eorum lucerna in aeternum extinguatur, nisi forte repuerunt, et Ecclesia Dei quam lesurunt, per emendationem et condignam penitentiam satisfecerint."—An excommunicated person was proscribed as unworthy of the commonest enjoyments of social life; no one, not even his wife, children, or servants, was permitted to come near him, under pain of the lesser excommunication; he forfeited every natural right and legal privilege; and could not act in any public capacity, or succeed to any private inheritance. If he did not make satisfaction to the church, and procure absolution from the bishop within 40 days, he was laid hold of by the secular power, his property seized, his person imprisoned, and all his offices vacated; and if he died unabsolved, his body was not allowed to be buried, but ordered to be swung into a pit, or covered over with stones.

In the Greek church, the formulas of excommunications are not less dreadful than they anciently were in the church of Rome. The most frivolous offences, equally as the most heinous crimes, are visited with it; and the person who has been guilty of them is declared, if he do not repent, to be "separated from the Lord God Creator, to be accursed and unpardonable, and undissoluble after death." Then follow such imprecations as these: "Let wood, stone, and iron be dissolved, but not he: May he inherit the leprosy of Gehazi, and the despair of Judas: may the earth divide and swallow him up, like Dathan and Abiram: may he sigh and tremble on earth like Cain, and the wrath of God be on his head: may he reap no fruit of his labour, and beg his bread all the days of his life: may his works, his possessions, his labour, and his services, be accursed, always without effect or success, and blown away like dust: may he have the curses of the holy and righteous patriarchs, Abraham, Isaac, and Jacob, of the 318 saints who were the divine Fathers of the Synod of Nice, and of all other holy Synods: and, being without the church of Christ, let no man administer to him the things of the church, or bless him, or offer sacrifice for him, or give him the Annier, or the blessed bread, or eat, or drink, or work, or converse with him; and, after death, let no man bury him, under penalty of the same condemnation." Such is the superstitious ignorance of the common people of this church, that they are said firmly to believe that the dead bodies of the excommunicated not only remain unconsumed, but are possessed with evil spirits; are fed and nourished during the night, and have been found 40 days after death, as ruddy in their complexion, and full of blood, as if they had been in perfect health. To prevent this, their relations are accustomed to cut their body in pieces, and boil them in wine.

In England, excommunication is incurred by contempt of the Bishop’s Court, neglect of public worship, profane desertion of the sacraments, heresy, adultery, simony, &c. But if any spiritual judge pronounce this highest ecclesiastical censure for an offence of which he has not the legal cognizance, the injured party may prosecute him at common law, or he may be indicted for it by the public prosecutor. According to law, excommunication disqualifies a person for serving upon juries, for being a witness in any court, and even for bringing any action, either real or personal, for the recovery of a debt, or the inheritance of property. Nay, if the culprit does not, within 40 days after the sentence has been duly promulgated, submit and abide by the sentence of the spiritual court, on the bishop’s certifying such contempt to the king in Chancery, a writ called excommunicatio apiendo, or, from the bishop’s certificate, significavit, may be issued, requiring the sheriff of the county to apprehend and imprison him, without bail or mainprize, till his reconciliation to the church is effected and certified by the bishop. This power, however, is now seldom exercised, and in general with becoming equity and moderation.

By the constitution of the Church of Scotland, the same crimes are punishable with excommunication as in England; but it is now seldom inflicted, except for continuancy. When the lesser excommunication (which involves only suspension from the sacraments) has failed of its desired effect, or, summarily, in the case of some particularly heinous offences, after the preparatory forms have been gone through, the officiating clergyman pronounces the sentence of higher or greater excommunication, in the following or similar words, to the person himself if present, or concerning him if absent: "Whereas thou N. hast been, by sufficient proof, convicted of——, and after due admonition and prayer, remainest obstinate, without any evidence or sign of true repentance; therefore, in the name of the Lord Jesus Christ, and before this congregation, I pronounce and declare thee N. excommunicated, shut out from the communion of the faithful, debar thee from their privileges, and deliver thee unto Satan for the destruction of thy flesh, that thy spirit may be saved in the day of the Lord Jesus." The people are then warned to avoid all unnecessary intercourse with him; but at the same time the sentence does not dissolve the bonds of civil or natural relations. Anciently, the excommunicated were, by the law of Scotland, incapable of holding feudal rights; but now, no civil penalty or disqualification is attached to this severissima disciplina, et ultimum fulmen Ecclesiae.

Among the ancient heathens also, excommunication was by no means infrequent; and consisted of two kinds, the less and the greater. Under the first, may not improperly be considered as included, such proclama-
in Devonshire, in the hundred of Wonford. The town is delightfully situated on the slope of a rising ground, on the eastern bank of the river Exe, which winds round the south-west side of the city. It is surrounded with walls, which inclose a space four furlongs long, and three broad, nearly in the form of a parallelogram. This space is intersected by four principal streets, nearly at right angles, which have lately been well paved and flagged, and which meet at a point where a magnificent conduit called Carfax, formerly stood, from the Norman words quatre voix, signifying four ways. The whole extent of ground occupied by buildings, is about 1/3 of a mile long, and one mile broad. All the gates have been taken down excepting the south-west gate. The remains of Rougemont castle, which derives its name from the red colour of the soil on which it stands, are situated on the north-east, and highest part of the city. It was erected by the West Saxons, and was very strong, both by nature and art. Its exterior wall, inclosing a pentagonal space, is now all that remains of it.

There are no fewer than 15 parish churches within the walls of the city, and four in the suburbs, besides several chapels, and a Jewish synagogue.

The cathedral is a large and magnificent building, dedicated to St Peter. It was begun in the reign of Athelstan, in 952, and though carried on under various bishops for 400 years, it was completed with the same uniformity as if it had been done by a single individual. The north tower, which contains a bell weighing 17,472, or 12,500 lbs. according to another statement, was finished in 1484. The cathedral was repaired and new pavi-ved in 1763; and a most beautiful modern painted glass window was put up over the west door in 1766. The cathedral consists of a nave, with two side aisles, two short transcepts, formed out of two ponderous Norman towers, in 1256, and a chapter-house, in the form of a parallelogram, built in 1430; a choir, with side aisles, which was finished in 1518, and ten chapels, or oratories, with a room denominated the consistory court. On entering the cathedral from the west door, the nave has a striking and magnificent appearance. It is 76 feet wide within the walls, and 175 feet long, from the organ screen to the western door. The roof is sustained by 14 huge clustered columns, supporting 16 pointed arches, above which are two tiers of small open arches. The choir is of the same width as the nave, and is 128 feet long. St Mary's chapel is 51 feet long, and there is a space of 25 feet between it and the altar screen. The whole length of the cathedral, from east to west, is 408 feet, including the walls. The roof is 69 feet high, and the Norman towers 130 feet to the top of the battlements. These towers have the same shape and character; they have a massive and grand appearance, but are inferior, in point of architecture, to the ornamented parts of the cathedral. The windows of the cathedral are very large, and are adorned with tracery and painted glass. The east and west windows are particularly fine; the western one is 37 feet high by 27 broad. The lower part is divided into nine compartments, seven of which are occupied with full length figures of saints. In the north tower there is a curious clock, presented to the cathedral by Bishop Courtenay. The organ is very large, and is reckoned one of the finest instruments of the kind in England. The other principal buildings are the bishop's palace, session house, the new gaol, the barracks, the circus, the theatre, the guild-hall, the lunatic asylum, and the county hospital. The bishop's palace stands near the south-east side of the cathedral,
and is a venerable fabric built or enlarged by Bishop Courtenay. The session house was some time ago erected in the area inclosed by the walls on the north-west side; it is an elegant building of Porland stone, and the assizes, quarter-sessions, and county-courts, are held there. The new gaol for the county is situated on the north side of the city, below the castle hill. It is built of brick, from the designs of Blackburn, and is elegant without and well arranged within. The barracks, which are erected near the gaol, are capable of accommodating 200 cavalry. The circus is built on the site of old Bedford house, on ground belonging to the Duke of Bedford; and near it is situated a small theatre. The site of the birthplace of Henrietta, sister to Charles II, lies more to the south-east part of the city. The buildings erected upon it are very handsome, and are intended to form Henrietta Place. Her portrait, by Vandyck, is now in the Guild-Hall, and was presented to the city by Charles II. The Guild-Hall, which is commodious, was repaired in 1720. The lunatic asylum is a large and elegant building, containing 48 apartments, and is furnished with hot, cold, shower, and vapour baths. The patients are classed according to their various degrees of insanity, and there is a fine extensive airing ground set apart for their use, are separated by lofty brick walls. The Devon and Exeter hospital for the sick and indigent poor, was founded in 1740, by Dr Alured Clark, Dean of Exeter, aided by public subscriptions. It was opened on Jan. 1st, 1747. There is also, in Exeter, an infirmary for diseases of the eye. Besides various Sunday schools, there are eight regular schools for educating and clothing, and two institutions for maintaining poor children. There are also various almshouses for the aged and infirm, the principal of which is called Wyndard's or God's House. Each person has a neat habitation, with a small garden, and a weekly and an annual pension. An elegant stone bridge, which cost between £18,000 and £20,000, is built over the Exe. It was begun in 1770. On both sides of it are houses, with a church over the greater part of it.

The trade of Exeter was formerly very extensive, from the navigable arm of the sea which flowed near its walls, but, however, to a ridiculous dispute between the inhabitants and Hugh Courtenay, the Earl of Devon, that nobleman most unwisely turned the navigation by building weirs and dams in various parts of it, so as to prevent all vessels from passing or repassing. The tide had hitherto flowed beyond the city, but it now only reached Topsham, a town about 3½ miles nearer the sea. The navigation of the river was, however, restored with some difficulty, by a canal which was cut from Topsham to Exeter. The navigation was still farther improved in 1695, when the present haven was constructed. By the erection of sluices and floodgates, vessels of 150 tons burden have been enabled to discharge their cargoes at a good quay made near the walls of the city, where the custom-house is built. The total declivity from the quay at Exeter to the lowermost floodgate at Topsham, is 8 or 10 feet.

The woollen manufacture is the principal source of employment for the labouring classes. Serges, druggets, duros, kerseys, and everlasting parts, are brought in a rough state from the vicinity of the town, and are dyed and finished by lowly-salaried workers for exportation and home consumption. Quantities of these goods, to the value of £500,000, are annually exported to Spain, Portugal, Germany, and Italy; and long-ells, to the amount of £400,000, are annually purchased by the East India Company. A large cotton manufactory, established on the banks of the Exe, formerly gave employment to about 300 persons, but it has now entirely failed. A very considerable and valuable wine trade is carried on in the town.

The Corporation, which has considerable revenues, consists of a mayor, 24 aldermen, a recorder, chamberlain, town-clerk, sheriff, four stewards, and several officers of inferior note. The corporate bodies within the city are 15, and each of them is governed by officers chosen annually. Markets are held here on Wednesday, Sunday, and Saturday; and the fairs are on Ash-Wednesday, Whit-Monday, August 1st, and December 6th, for horses, cattle, sheep, and almost every commodity.

Exeter has the advantage of several very pleasant walks; the one on the north, encompassing the upper sides of the castle, and extending nearly from East Gate to North Gate, is a most delightful airy terrace, and is uniformly admired for its beauty. It was planted with elms in 1664. Above the quay, on the south side, is the fine terrace called the Friars. It rises above the river to the perpendicular height of 100 feet, and commands a most extensive and beautiful prospect. The air of Exeter is very salubrious, the average of burials being as 1 to 37 of the population.

The following is an abstract of the population-return for the city of Exeter, in 1811:

Number of inhabited houses 2,879
Number of families that occupy them 4,468
Number of uninhabited houses 92
Number of families chiefly employed in agriculture 156
Do. employed in trade, manufactures, &c. 2,888
Males. 7,908
Females 10,998
Total population in 1811 18,896

West Long. 3° 30' 34", North Lat. 50° 44'. See Povywhale's History of Devonshire; Jenki's History and Antiquities of Exeter, 1800; the Beauties of England and Wales, vol. iv. p. 46—88; but particularly Sir Henry Englefield and Dean Lyttelton's Historical Account of Exeter Cathedral, with several prints from drawings of Mr J. Carter, published by the Society of Antiquaries. An engraving of the north tower of Exeter Cathedral, and of the south gate of the town, are given in the Beauties of England and Wales, vol. iv. (w)

EXFOLIATION. See Surgery.

EXHALATION. See Evaporation and Meteorology.

EXMOUTH, is the name of a celebrated watering place in Devonshire, situated on the north side of the mouth of the river Exe. About a century ago, it was only a small hamlet inhabited by fishermen, but it was brought into notice by one of the judges of the circuit, who received great benefit from it as a bathing place. Exmouth is situated near the sea, between the cliffs, which as it were open to receive it. It is sheltered on the north-east and south-east by some high hills, which rise behind the town, and supply it with excellent water. The town is furnished with every accommodation as a watering-place, and has a good assembly-room. The houses are in general low and inconvenient, though well built, but some of them are good and elegant. The walks are delightful, and command extensive and picturesque views. The prospect from Chapel Hill embraces a line of coast extending for 20 miles from Exeter to the Berryhead. Several hills by which gradually ascend from the coast on the opposite side of the river, break this line; and behind these
Exonouth has a chapel of ease, and is a chapelry of the parish of Littleham. According to the population returns for 1811, the parish of Littleham and the town of Exonouth contained 439 inhabited houses, 473 families, 5151 males, 1283 females, and a total population of 4391. See Polywhele's History of Devonshire, vol. ii, p. 215. (m)

EXOTERIC, is a term applied to the public doctrine of the ancient philosophers which was openly taught to the world, the exoteric or academic doctrines being confined to a small number of select disciples. (m)

EXPANSION, from the Latin expansio, 'I expand,' is a term employed in physics, to denote that increase of magnitude which almost all bodies, whether solid, fluid, or gaseous, receive from an increase of temperature. The instruments by which the expansions of solid bodies are measured, are called Pyrometers, which were originally constructed by means of multiplying wheels, screws, and levers; but they have recently been constructed with micrometer microscopes, which enable us to measure the expansion of solids with singular accuracy. By means of a pyrometer, Mr. Ellicott obtained the following expansions for seven metallic bodies, by the same elevation of temperature.

Berthoud's. M. Berthoud obtained the following results with rods three feet two inches and five lines long, five lines wide, and three lines thick, which were placed in a situation where the thermometer rose from 0° to 27° (of Reaumur, probably). The measures are given in parts of a line.

Experiments of a similar kind were made by Smeaton, Ramsden, Muschenbroek, Borda, General Roy, and Mr. Troughton.

In 1749, Mr. Troughton made a pyrometer for Capt. Mendoza, similar to that made by Ramsden, and described by General Roy in the Philosophical Transactions for 1785, and the instrument having remained some months in his possession, he embraced the opportunity of examining the expansions of brass, steel, cast iron, and flint-glass. The following were the results which he obtained:

<table>
<thead>
<tr>
<th>Material</th>
<th>Expansion on one inch with 60° of the mercurial thermometer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brass</td>
<td>.000640.</td>
</tr>
<tr>
<td>Steel</td>
<td>.0003966.</td>
</tr>
</tbody>
</table>

The results for cast iron and flint glass have unfortunately lost. Although these measures were obtained after frequent repetitions of the experiments, made with the greatest care, yet they differed considerably from those obtained by General Roy.

In 1794, Mr Troughton constructed a pyrometer on a new principle; but as it was only designed for trying pendulums in a finished state, a length greater than 40 inches could not be subjected to trial. With this instrument he obtained the following results:

<table>
<thead>
<tr>
<th>Material</th>
<th>Expansion on one inch with 60° of the merc. therm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Silver</td>
<td>.000694.</td>
</tr>
<tr>
<td>Iron</td>
<td>.000480.</td>
</tr>
<tr>
<td>Platinum</td>
<td>.0003350.</td>
</tr>
</tbody>
</table>

Mr Troughton considers all the experiments which have hitherto been made on the expansion of solids, as undeserving of confidence, and he proposes to construct a new pyrometer of the kind already mentioned, so as to be able to receive a ten feet rod. A series of experiments made with such an instrument, and by a philosopher of Mr Troughton's known accuracy, will be a most acceptable present to the physical sciences, and will probably lead to a determination of the law which regulates the expansion of solid bodies.

The results of the best experiments we have given in the following valuable Table; for which, with the exception of a few additions, we are indebted to Dr. Thomas Young. It exhibits the increase both of length and bulk for 180°, and for 1° of Fahrenheit's scale.

* Mr Troughton has been so kind as to promise the Editor a description of this ingenious instrument for the article Pyrometer.
† These results are now published for the first time.

</table>

It has been found, in general, that equal increments of heat produce a greater expansion at a high temperature, than they do at a low one.

The expansion of metallic bodies seems to have some connection with their fusibilies. Platinium, the least fusible of the metals, has the lowest expansion; and lead, one of the most fusible, has the greatest expansibility. The most fusible glass is also found to be the most expansive.

---

From a number of experiments made with Prince Rupert's drops, which are formed by dropping melted metals on glass into cold water, Dr. Brewster has endeavoured to obtain a measure of the expansion of glass when in a fluid state. When the drops are made of flint glass, they contain a number of cavities formed by the contraction of the glass in cooling. These cavities contain no air. They increase with the magnitude of the drops, and may therefore be considered as a measure of...
the contraction which the glass undergoes in its transition from the temperature at which it melts, to the ordinary temperature of the atmosphere. The magnitude of this contraction is measured by the difference between the specific gravity of the annealed and the unanneled glass. This measure of the contraction must always err in defect, but the maximum result obtained from a considerable number of drops, may be regarded as a tolerably correct measure of the diminution of density. Those drops should be employed in which the cavities are most numerous, and scattered over every part of their length. In some large drops of flint glass, the number of cavities is given. Dr Brewster found that the specific gravity of unannealed flint glass was 2.30405, and that of annealed flint glass, from the same pot, 2.3263. Hence the expansion in passing from the fluid to the solid state, is greater than \( \frac{1}{45.5} \) or 0.002205. See the Phil. Trans. for 1815, p. 1, where a full account of these experiments is published.

Cast iron, antimony, and bismuth, form exceptions to the general law of expansion, as they actually increase in bulk in passing from the solid to the fluid state. Mr Mushet has established this fact for cast iron, by numerous experiments, which prove that it is most dense when fluid, and that it acquires its greatest volume in passing from the fluid to the solid state. The contraction of argillaceous bodies, by an increase of temperature, will be described in our account of Wedgwood's Thermometer.

### On the Expansion of Liquids.

We have already remarked, that all fluid bodies are also expanded by an increase of temperature. The common method of measuring these expansions is to enclose them in a glass tube, and to observe the different heights to which they rise when subjected to different temperatures. These heights diminished by the expansion of the glass tube, will afford an accurate measure of the expansion of the included fluids. In this way M. De Luc made a number of experiments, which we have given in the following Table, the degrees in the first column being those of Reaumur's thermometer.

</table>

By examining the results in the preceding Table, it will appear that the expansibilities increase rapidly near the boiling point, and that near the freezing point there are considerable irregularities. If we divide the scale of the thermometer between the freezing and the boiling point, and between 0° and 80° of Reaumur, or 32° and 212° of Fahrenheit into two equal parts, viz. from 0° to 40°, and from 40° to 80° of Reaumur, or from 32° to 122°, and 122° to 212° of Fahrenheit, Deluc found that fluids expand more in the higher di-
The results for water contained in the last column of the Table, exhibit a very remarkable deviation from the general law observed by all the other fluids in the Table, as it possesses the remarkable and anomalous property of having its maximum density at 40°, and consequently of contracting when its temperature is either diminished or increased. This property of water, first observed by the Florentine Academicians in 1607, seems to have been first accurately examined by Dr Cronne towards the end of the 17th century. Dr Hook ascribes the phenomenon to the contraction of the vessel; but it has been shewn, in the most satisfactory manner, by the experiments of Mairan, De Luc, Dr Hope, Mr Dalton, and Sir Charles Blagden, that the phenomenon is not the result of any illusion. Sir Charles Blagden has proved that if water be kept free of all agitation so as to prevent it from being frozen at 32°, and is cooled down to 21° or 22°, the expansion still continues under an increasing ratio. Mr Dalton fixed the maximum density of water at 42° of Fahrenheit; he found that the expansion was scarcely perceptible from 41° to 44°, and that from 41° to 32° the expansion was about 1/75 th part of the whole expansion from 42° to 212°. He confirmed Deluc's observation, that the expansion for any number of degrees, either above or below 42° was the same; but he afterwards thought that it was greatest below 42°. He also verified the observation of Sir Charles Blagden, that the expansion continues below 32°, and he succeeded in cooling it so far down in a tube that the water had expanded and risen to the same height as if it had been heated to 75°. Hence, it must have been cooled down to 10°. As soon as it was frozen, it sprung up to 128°.

These remarkable appearances were regarded by several philosophers as so anomalous, that they were probably occasioned by some hidden source of error in the experiments; and even Mr Dalton himself was induced to believe, that the anomaly exhibited by water was only apparent, and arose from the contraction of the vessel in which the experiment was made. In order to investigate this point, he repeated the experiments in earthen ware and metallic vessels, and compared the results with those made in glass. In all these trials, the point of maximum density, instead of being the same, varied with each substance, as will appear from the following Table:

<table>

Notwithstanding the accurate experiments of M. Lejeure Gineau, who proved the maximum density of water to be 39°.2, the results obtained by Mr Dalton threw a considerable degree of uncertainty over the subject, and chemists were divided in their opinions, till the subject was investigated by Dr Hope in a new manner, which was not liable to any error arising from the contraction of the containing vessels. It occurred to this learned chemist, that if water expanded by a diminution of its temperature below 40°, the expansion might be rendered visible by the change of place, which would happen in a column of water when cooling from 40° to 32°, or when heating from 32° to 40°, as the water, which had a temperature of 32°, would necessarily rise in both cases towards the surface. He therefore filled a glass jar, 8½ inches deep and 4½ broad, with water at the temperature of 62°, and succeeded in it two thermometers, one having its bulb about half an inch from the bottom, and the other about half an inch from the surface. The vessel being placed in a room having the temperature of 68°, it was found that as the temperature rose to 38°, the thermometer at the surface was always one degree lower than the one at the bottom; a sufficient proof that the density of the water increased as its temperature rose above 32°. In order to obtain a still more striking result, Dr Hope employed a jar 21 inches high, and four in diameter, and he adjusted at the middle of its height a basion of tinned iron, by filling which, either with hot water, or a frigorigine mixture, he could apply heat or cold to the middle portion of the fluid column. A thermometer being fixed at the top and bottom of the jar as before, the jar was filled with water at 32°, and water of the temperature of 68° was poured into the bason of tinned iron. The lower thermometer rose from 32° to nearly 37° before the upper thermometer indicated the smallest increase of temperature, the warm current having moved downwards in consequence of the contraction or increase of density of the water. Dr Hope reversed this experiment by filling the bason with a frigorigine mixture, while the water in the jar had a temperature of 39°. The upper thermometer descended to 33° in the course of two hours, while the lower one suffered almost no change, the current of cooled water ascending to the top of the jar. By thus varying his experiments in a very beautiful and skilful manner, Dr Hope decided the question of the maximum density of water, and is entitled to the honour of having been the first who really established the existence of this singular anomaly.

When the writer of this article had the pleasure of seeing Monsieur Arago at Paris in the course of last summer, he mentioned to him a series of experiments made on the refractive power of water at different temperatures, in order to determine if its maximum density was above 32°. He filled a prism with water at the temperature of 32°, and observed the angle of deviation produced by refraction, while its temperature rose from 32° to 212°. The angle of deviation was greater at 32°, and it gradually diminished to 212°, exhibiting no marks whatever of a variation of refractive power at 40°, or at any point between 32° and 212°. Hence Monsieur Arago concluded, that since the refractive power always increases with the density, the density of water must be at a maximum at 32°. This conclusion might have been admitted to have considerable weight, before Dr Hope had established the opposite conclusion by direct experiment; but, independent of this circumstance, we have no hesitation in saying, that M. Arago's conclusion is
not legitimately deducible from his experiments. It is assumed in his reasoning, that the refractive power of bodies increases with their density, a doctrine which requires to be established by direct experiment, before it can be admitted as a valid argument in favour of any other position. Nay, it has actually been proved by Albert Euler from numerous experiments, that the refractive power of glass is increased by heat. An augmentation of temperature of 60° of Reaumur diminished the focal length 1/4th part, and an augmentation of 33° produced a diminution of 1/7. M. Euler concludes, without sufficient evidence, that the refractive power of all fluids is increased with heat; but though this is obviously erroneous, yet the experiments which he has made completely overturn the assumption of M. Arago, that the density at different temperatures may be inferred from the refractive power, and leave the subject of the maximum density of water in the same state as it had been left by Dr Hope.

No experiments, so far as we know, have been made, with the view of explaining this singular property of water, nor does it readily appear how such experiments could be made. We have often thought that an incipient crystallization takes place at the point of maximum density, and gradually increases till the congelation is completed. But in what manner are we to render this incipient crystallization apparent? It is not visible to the eye; nor can it be detected by the application of any known instrument. It has often occurred to us, that it may be rendered visible, if it does exist, by the action of the water in depolarising a ray of polarised light, a property which is possessed by the water as soon as it is converted into ice. We have shown from numerous experiments, that a piece of glass which has no depolarising structure, receives it by an augmentation of temperature, and again loses it when the temperature diminishes, and this communication and destruction of the depolarising virtue takes place when the glass is perfectly solid. Hence it is reasonable to infer, that water, though still in a fluid state in passing from 40° to 32°, may be gradually receiving that peculiar arrangement which is necessary to depolarise light, and which belongs to crystallized bodies. Several months ago, we tried this experiment in a very rude manner, by melting a quantity of snow between two plates of glass, and, after the snow was completely melted, a considerable quantity of light was depolarised. As this effect, however, might have been produced by some invisible portions of unmelted snow, we do not consider the experiment as worthy of any confidence. We have, however, begun a series of experiments, for the purpose of determining this interesting point.

We shall now conclude this branch of the subject, with a tabular view of the different experiments that have been made on the expansion of mercury, water, the acids, and alcohol, which have been collected and arranged in a tabular form by Dr Thomas Young.

Spirit highly rectified, specific gr. at 60°. 825.
The formula used in the preceding Table is
\[ T = a + bT + cT^2 \]
the temperature being \( T \) or reckoning the degrees from 60, 1, etc.

From a diligent comparison of the observations of De Luc, and other natural philosophers, M. Biot of the Institute of France has succeeded in discovering the law of the expansion of fluids; and by means of a very simple formula, he has been enabled to calculate the true dilatation corresponding to any given temperature. These interesting investigations have not yet been published; but M. Biot has had the kindness to communicate to the Editor a general account of his labours.

In all fluids whose expansions have hitherto been examined, the true dilatation \( T \) reckoned from \( T \), is capable of being expressed by the formula
\[ T = a + bT + cT^2 \]
where \( a, b, c \) are three coefficients constant for each liquid, but varying in different liquids. M. Biot has determined the value of these coefficients for eight or ten fluids, which are most frequently employed. The preceding formula is applicable with equal accuracy at all temperatures, while the fluid exists in some state of fluidity, and continues to be heated. It may, therefore, be extended even beyond ebullition, if the fluid is contained in a tube where it cannot boil. The preceding formula likewise agrees with a set of fine experiments made by M. Charles, with an instrument of his own invention, for rendering sensible, and measuring the maximum expansion of water. A full account of M. Biot's investigations, will be found in the third volume of the *Memoires d'Arcueil*, which is now in the press; and also in a complete treatise on natural philosophy, with which M. Biot is at present occupied, and to the appearance of which we look forward with the highest expectations.

On the Expansion of Gases.

The subject of the expansion of gases, has been investigated by Priestley, Ray, Sansure, Monge, Guyton, Duvernos, and Prony; but the most accurate are those which have recently been made by Gay Lussac, and our countryman Mr. Dalton. The results obtained by some of these eminent chemists, are given in the following Table drawn up by Dr. Thomas Young.

**Table of the Expansion of Gaseous Bodies.**

Mean of six observations, Lacaille making it .04, Mayer .046, Bonne .0477, Shuckburgh .0505, Bradley .0544, and De Luc .047, for the expansion. From 32° to 54.8°: the mean .0476, De Luc.

Mayer's refractions, Gilbert.

Lambert.

De Luc, reduced by Gilbert.

Laz, .0476.

About 95°, and De Luc.

About 172°, and De Luc.

Roy; but moisture was admitted.

Schmidt: thinks it perfectly uniform, becoming 7. at 392°.

La Place, Systeme du Monde.

Gay Lussac, corrected for the expansion of glass, = .003 or .0033.

Dalton, reduced by Gilbert.

About 95°, and De Luc.

About 172°, and De Luc.

Roy.

When additional moisture is excluded. Saussure.

| All as air. Gay Lussac, and Dalton. |

It follows from these experiments, that all the gases undergo the same expansion from the same increase of temperature, the expansion for each degree of Fahrenheit being \( T \) according to Dalton, and \( T^2 \) according to Gay Lussac. An account of the expansion of the vapour of water, will be found in our article Steam.

EXPO NENTS. See Algebra.

EXPORTATION. See England.

EXPRESSION. See Painting.

EXTENDED THIRDS, in Music, according to Mr Marsh, Theory of Harmonies, p. 20, are the same as the "wolf thirds," or those on which the greatest imperfection or result of the temperament falls: usually on XGc, DEG, and XCF, in the major thirds; EFG, and XBC, and XGc, in the minor thirds. (c)

EXTRACTION of Roots. See Arithmetic and Algebra.

EXTREME INTERVALS, in Music, are, according to Dr Callcott, "such distant distances as are increased or diminished by a chromatic semitone," (Gram. 1st ed. p. 115.) and this alteration at page 112, is defined to be the same with a flat or a sharp; yet, except in the obscure and incorrect section (228) in p. 119, the study is no where advised by this author, that sometimes the minor, and at others the medio semitone (3 or 5) is his chromatic semitone. Dr R. Smith, and Mr Liston, (Essay, p. 24.) denote all those intervals extreme with respect to C, which arise in modulating therefrom by fifths, either above XGc, or below XBC. The several extreme flat intervals of the authors when arranged, are XII, or 2 (—5); X9 (—5); X6 (—5); XIV, or 4 (—5); XV, or 5 (—5); XIX, or 6 (—5); XIXV, or 7 (—5); and XIXVIII, or 8 (—5).

And the several extreme sharp intervals are, XIX (1+5); XIXII (1+5); XIXIII (1+5); XIXIV (1+5); XIXV, or 7 (—5); and the extreme double sharp interval XIXIXII, or 7 (—5—5); and the extreme double sharp interval XIXIXIXII, or 7 (—5—5).

The letters 3 or 5, and their signs + or —, denoting the increase or diminution of the interval, by X5+I+3m, or X5+I+4m respectively, whence the value of any of them may be easily had; or see the several intervals Eighth, Fifth, First, &c. (c)

EXTREME DIMINISHED and Extreme Superfluous intervals, according to Mr Chambers, are diminished or increased by 2d; but Mr Overend says by 3+5, which answers to the double flattening or double sharpening above. (c)

EYE. See Anatomy, Medicine, Optics, Physiology, and Surgery.

EYLAU, Preusisich, or Prussian, a small town in East Prussia, south-east of Koningsberg, of little note till it became the scene of a most sanguinary engagement between the French and Russians, on the 8th February 1807. The Russian army having retreated during six days, reached on the 7th February the position behind the town of Eylau, where general Benningsen had promised to his impatient followers to give battle to Bonaparte. The ground was chosen, less from a consideration of its being favourable to the Russians, than with a view to the preservation of the city of Koningsberg. The length of the position was two miles; it was partly flanked by woods, but, on the whole, the ground was elevated and exposed. The French took post on ground nearly parallel, but higher, so as to command with their artillery the Russian position. The French had likewise the superiority in numbers, the Russians not exceeding 60,000 men. On the evening before the battle, there was a most sanguinary struggle for the town of Eylau, which finally remained in possession of the French. The armies passed the night in the immediate neighbourhood of each other, and eager for the approaching conflict. The cannonade began at day break, and was conducted at first with greater effect on the part of the French, in consequence of the Russian line standing more exposed. The space between the armies, though marshy in open weather, was easily passable at this season of ice and snow. Bonaparte accordingly made two large columns move forward, the one against the centre, the other against the right of the Russians; but after advancing 300 yards, the havoc of the Russian artillery was so great as to break their order, and they returned in confusion. A subsequent effort directed against the Russian left, was equally unavailing, the Russians advancing and driving back their opponents with the bayonet.

These operations, however, were merely preparatory to Bonaparte's general attack. Calculating that Davoust, whom he had detached to take the Russians in the rear, would arrive at his station towards noon, Bonaparte directed a general movement of his army, including the guards, in six separate columns against the Russian line. A heavy fall of snow concealed his arrangement, and favoured the approach of the columns, so that they were not discovered till they had come very near to the Russian line, upon which general Benningsen, aware of the importance of the moment, made his reserve advance, join themselves to the main body, and rush forward, with united strength, to charge the enemy. The French were shaken, gave way, and all the efforts of their officers to rally them were ineffectual. Their cavalry attempting to turn the fortune of the day by desperate charges, were cut up in great numbers; but the Russians had hardly effected this repulse, when they were ordered to face about, a numerous corps appearing on their left, and threatening their rear. This was the corps of Davoust, who had fortunately been retarded by the wretched state of the roads. The Russian main body was drawn back from the field of battle to meet him; and a Prussian corps under general Lestocq having, after a most difficult march, reached the scene of action, advanced to attack Davoust. Their number did not exceed 6000; but they were admirably commanded by Lestocq, and the Russian left wing affording them support, the French were repulsed with very heavy loss. Night now came on, and Bonaparte recalled Davoust. Had the Russians been in a condition to make an attack the next day, their success would have been certain; but their ammunition was expended, and their men were fainting for want of food. By an irregularity unfortunately too common in the Russian commissariat, there had been no supply of provisions that day; and Benningsen, apprehensive for the eventual safety of Koningsberg, took the determination of retreating, contrary to the concurrent wish of his generals. The Russians acknowledged a loss of nearly 20,000 men in killed and wounded, and maintained that that of the French exceeded 30,000. Bonaparte remained for some time at Eylau, but finding that the Russian cavalry were competent to the protection of the surrounding country, and that he could make no effectual progress against so resolute an enemy, he retired in the direction of Dantzie. FAUCEL. See Astronomy.

FAENZA, the Faenitia of the ancients, a city of Italy, and capital of the department of the Amone, is the see of a bishop suffragan of Ravenna. Mr. Eustace, the latest author of travels in Italy, describes this ancient town as spacious and well built. Its great square has a fine range of porticos on either side, and a Corinthian church belonging to the Dominicans. The cathedral, which is Gothic, stands in the great square, and is ornamented with a handsome steeple, five stories high, with ballustrades. There is a fountain near the church, having a basin surrounded with four lions of brass, and encompassed with a wrought iron rail. Faenza was once celebrated for its pottery, from which it received its name. The pottery obtained also the name of Majolica, from the inventor of it. Mr. Eustace observed in the vicinity of this city, a few traces of the pine groves, which appear to have formed one of its distinguishing features in ancient times. Distance from Ravenna, 20 miles south-west. North Lat. 44° 18', East Long. 11° 51'. See Keysler's Travels, vol. iii. p. 246; Eustace's Classical Tour through Italy, vol. i. p. 142, 143. (n)

FALULUN, a town of Sweden in the province of Dalecarlia, is situated about 300 feet above the level of the sea, between the two lakes of Run and Warpen, in a small plain, surrounded on all sides by low hills. The town, which owes its existence to the celebrated copper mines in its neighbourhood, is very regular, and consists of several parallel streets, crossed at right angles by many others. The houses are principally built of wood and of stone, and there are two churches in the town built with brick, and one of them roofed with copper. The following very interesting and accurate account of the celebrated copper mine, is abridged from the full account given by Dr. Thomson, in his recent travels in Sweden. "The mine of copper-ore consisted of an immense cone of copper and iron pyrites, placed with its apex downwards. It has been wrought from time immemorial, and formerly with so little care, that about 150 years ago, the whole works fell in, leaving a great hollow, still very conspicuous as we approach the mine. Two large pillars, or rather hills of quartz, however, remained unmoved amidst the ruins. They may be still seen rising through the bottom of the great excavation, formed by the trembling of the mine. For many years galleries were driven through the old works, and the ore extracted in that manner; but now the vast heap of ruins has been wrought out, and they are obliged to go deeper for the ore which at present they extract. The mine is about 500 fathoms deep. The descent is by an easy winding staircase all the way; so that you may descend to the bottom without any other inconvenience than the fatigue of going down so many steps. The galleries are all spacious; none less than eight feet in height, and some as high as thirty feet. There are about 600 workmen in the mine. The ore is extracted partly by the mallet, partly blasted by gun-powder. It is extremely poor, sel-

dom yielding more than 1½ per cent. of the copper. To the eye, indeed, it has nearly the appearance of iron pyrites. This pyrites is frequently mixed with beautiful crystals of actinolite, of considerable quantity, which gives it, when fresh broken, a very splendid appearance. This actinolite is likewise found in the neighbourhood in chlorite slate, crystallized in very regular four-sided prisms, about an inch in length, and having a greyish blue colour.

Whether the original great conical mass of ore constituted a vein or not, it is impossible to say; all means of tracing any things respecting its situation having been long ago destroyed. But several veins filled with a similar ore still exist, and have been wrought.

The ore is drawn up the perpendicular shafts; the principal one of which is King Adolphus Frederick's shaft. All the machinery belonging to this mine is driven by water; and as far as my observations went, the whole is constructed according to very scientific and sound principles.

The whole wood-work of the mine is impregnated with sulphate of iron. The water that collects in the mine contains likewise a portion of the same salt in solution. As this water contains likewise a little sulphate of copper, it is pumped up, and made to run slowly through a pretty long trough, containing pieces of old iron. By this contrivance, the copper is precipitated. It is collected occasionally, and smelted. The water thus freed from copper, though it contains sulphate of iron, is by much too weak to render it profitable to crystallize the salt by means of heat.

It is concentrated by a very ingenious method, borrowed from the method used in Germany to concentrate some of their weak salt mines. The water is pumped up to the top of a pretty high wooden stage, all wrap round with birch twigs. It is let fall upon these twigs, and trickles over them to a trough at the bottom of the stage prepared to receive it. By this contrivance, a very great surface of the liquid is exposed to the air, which greatly facilitates its evaporation. This process is repeated six or seven times, as the liquid moves along from one extremity of the stage to the other. By this time it is so much concentrated as not to be very far from the point of crystallization. From this stage it runs into a large vessel lined with lead, where it is sufficiently concentrated by boiling. It is then let into a number of small square wooden vessels, set beside each other in a large apartment for the purpose. Into each of these vessels a number of wooden rods fixed to a frame are dipped. Upon these rods the sulphate of iron crystallizes. The copperas thus manufactured is used in Sweden, and exported to different parts of the Baltic.

The whole surface of the plain on which the mine is situated is thick, strewed with immense round blocks of granite, quartz, felspar, hornblende, and chlorite slate. But not a single rock is to be seen in situ in the whole plain, except the two pyramids of quartz, in the excavation of the mine formerly mentioned. But upon the higher grounds which surround Falulun, especially to the west, rocks will be found exposed in considerable
quantity. The rock which environs Falhn is a particular kind of felspar, without exhibiting any quartz or mica which I was able to detect, though I pursued the course of the rock several miles. This rock is very much injured by the weather. I could not perceive any marks of stratification in it; but as the direction of the high ground is from south to north, that is the direction in which only it can be traced. I observed three great veins of hornblende cutting through this rock, and running in an easterly and westerly direction. In one of these veins there was a bed of quartz eight inches thick. Each of the hornblende veins must have been at least six feet thick. I observed likewise several veins of quartz not exceeding a few inches in thickness, running in the same direction with the hornblende veins.

The rocks on the east side of the mine, at the distance of some miles, are gneiss. From the minerals that accompany the copper ore, such as actinolite, tremolite, chlorite, and from several other circumstances, I have little doubt that the mine consists, in fact, of a series of veins in mica slate. The vein-stones appear to consist chiefly of quartz.

Falhn is the oldest, and for many years it was the most productive, mine in Sweden. It is known to have been wrought since the year 1477. Nor is there any reason to suppose the working of it began only then, though no authentic records go to a greater antiquity. In the year 1500 it yielded annually about eight millions of pounds of copper in the year; but for some time back, the produce has been greatly diminished, and there is every reason to expect that no great number of years will elapse before it ceases altogether to be productive. Those gentlemen who have the management of the mine, are sensible of this circumstance, and have been turning their attention to the iron mines in the neighbourhood, as a means of employing the workmen when the copper mine shall be exhausted. The governor of the province, who is himself possessed of some iron mines, and who conceives that the interference of those gentlemen would be injurious to his trade, has endeavoured to prevent them from carrying their views into execution.

The copper mine of Falhn is at present the property of a considerable number of individuals. When the ore is brought to the surface of the earth, it is divided into different portions according to the requisite shares of each individual. Every one is at liberty either to smelt his own ore in the way he thinks proper, or to dispose of it to those who are inclined to purchase it. From this method of proceeding it happens that there are a great many different smelting houses, and that each house conducts its processes upon a small and economical scale. Population of the town 6000. See Cox's Travels, vol. v.; Catton Voyage en Allemagne et en Suède, vol. ii. p. 292, Paris 1810; but particularly Thomson's Travels through Sweden, chap. xii. p. 216; and Plates ix. and x. of that work, which exhibit a ground plan of the copper mine, and likewise a perpendicular section of it. FAHRENHEIT. See THERMOMETER.

FAITFORD, a market-town of England in Gloucestershire, is situated in a pleasant country at the foot of the Cotswold hills, on the banks of the river Colne, at an old ford near the confluence of that river with the Thames. The town consists of two streets, neatly and regularly built, and is principally distinguished for its fine Gothic church, and the excellently painted glass which it contains. The church, which is dedicated to the Virgin Mary, is a fine specimen of the Gothic which prevailed about the end of the 15th century. It consists of a lofty nave, a chancel, side-aisles, and a low tower rising from the centre of the edifice, which has been supposed to have been intended for the foundation of a spire. The whole of the building, which is 120 feet long, and 55 broad, is embattled, and sustained by pinnacled buttresses, those of the tower being flattened, and gradually diminishing to the top. Statues, as large as life, are rudely sculptured on their bases; and round the architrave is a series of grotesque figures. The exterior is adorned with many niches, which had once contained carved statues. The architecture of the interior is remarkably fine: light fluted pillars, sustaining four arches on each side, divide the aisles from the nave. The aisles are continued parallel with the chancel, with which there is a communication by two arches of equal height. The chancel is adorned with a fine oak screen, adorned with finely carved tabernacle-work, and stalls of the same work. The pavement is chequered with blue and white stone. This magnificent edifice was founded by John Tame, an opulent merchant, who having, in 1493, taken a vessel laden with painted glass, and bound from a Flemish port to Italy, resolved to have a large building erected for its reception. Having been for some time settled at Faitford, he began the present church in 1493, and disposed of the glass in 28 windows, each having four or more compartments. The principal subjects of these paintings are scriptural, some of them are the Roman emperors, who opposed and who favoured the establishment of Christianity. The designs in the west window are the Resurrection and the Last Judgment, the colours of which are so brilliant, and the drapery so delicate, that Mr Dallaway regards them as a more pleasing specimen of ancient art than will often be met with in England or on the Continent. Vandyck considered some of the figures as so well done, that they could not be surpassed by the best pencil.

The church contains a variety of monuments and sepulchral inscriptions. A tomb of Italian marble is erected in the north aisle to the memory of Sir Edmund Tame, son of the founder of the church.

There is here a free school endowed for 60 boys, and other charitable institutions. The Colne is crossed by three bridges; and, about three miles from the town is the great canal which joins the Severn and the Thames. The inhabitants of Faitford chiefly subsist by its markets and fairs, which are well attended. The population of the town and parish, in 1811, was,

FAIFOE, or HAIFO, the name of a sea-port town of Cochinchina, situated on the banks of a river communicating with Turon Bay. The river was formerly navigable for large junks, but it will now admit only vessels of 100 tons burthen. The junks lie at the distance of about 3 miles from the town in another river.
communicating with that of Turon, and capable of receiving ships of 200 tons. The best anchorage is on the west side of the island of Chalm Calloa, in N. Lat. 15° 34', opposite the river, and about three leagues from the main. The town of Faifo, which is about 10 miles from the sea, was once very large, and possessed a flourishing commerce. The houses were built of brick, and the streets well paved. It was destroyed by the rebels during the civil wars, but is now recovering its former importance. The vessels which arrive at Faifo are principally Chinese, Japanese, and the country ships from India. A hundred Chinese junks are said to have come annually to Faifo before its decline. The principal articles which they exported into Faifo were alum, China ware, Congo tea, dried fruits, drugs, sticks of sandal wood, linen cloth, false pearls, ornaments, pepper of various kinds, dried blubber, dammar, ink, pisan glass, sweetmeats, tacts, lacquered ware, and great quantities of tutenague, the last of which the king always engrosses to himself. The Japanese import chiefly copper, and several articles similar to those enumerated. The country ships import several European and Asiatic commodities, such as brazier, cutlery, clothes, guns and gunpowder, saltpetre, silver, clocks and watches, tobacco, opium, gold lace, brimstone, cannon bullets, fur, glass ware, hardware, ironmongery, lead, looking glasses, mathematical instruments, paint goods, tin, sandal wood, swords, shot, and vermilion.

The exports from Faifo to China were principally boclocu nut, black wood, bullock's bones, calavances, cardamoms, cotton, dried sea mists, dried fish, drugs, pepper, Japan wood, powder, agala wood, beeche de mer, birds nests, blue, (a kind of smalls), cassa, clove and nutmegs, deer's sinews, mats of rattan, elephant's teeth and bones, fish glue, gamboge, coarse linen, rat-tans, wood for incense, seeds, skins of bullocks deer and elephants, stick lac, tin, wax, sugar, and sugar-candy in great quantities, which is reckoned the finest in the world. The exports to Japan were ebony, namorack, pepper, fish skins in great quantities, hare-skins, cow hides, buffaloes horns, white and dark sugar, Cambodia nuts, bark, drugs, Sellow, and silk stuffs. The exports to India are principally sugar-candy and sugar. Various articles are also exported to Batavia, Manilla, and Siam. The duty on all imports is 12 per cent.; and the master of every vessel must give in a statement of all his goods, and agree to pay a certain sum every time that the ship arrives. The Portuguese pay annually 5000 guans, (500 of which is equivalent to 2 rupees, or 1 Spanish dollar,) and the Chinese only from 1500 to 2000, according to the size of their junks. It is necessary to present the king with a piece of scarlet cloth, some fine long cloths, a sword, telescope, &c. and the principal mandarin at Hue, which is the royal residence, must also be attended to. See Milburn's Oriental Commerce, vol ii. p. 452.

Fairhead, situated in the county of Antrim, near the north-eastern angle of Ireland, and opposite to the island of Rathlin or Raphag, in Long. 6° 2' W. of Greenwich, and Lat. 55° 44' N.

This bold headland is composed of the most considerable mass of greenstone in the British islands. The greatest thickness of the bed is 200 feet, and its elevation above the sea 545 feet. The greenstone rests on strata of sandstone, which dip south-west, and in these, a little to the west, the coal mine of Ballycastle is situated.

Fairhead, in consequence of its superior elevation, is distinguished, in the language of the country, by the name of Bengore; it forms the eastern termination of Ballycastle bay, and is distant about eight miles from the basaltic district of the Giant's Causeway, known to mariners under the general name of Bengore Head. Nothing can form a more striking contrast than these two headlands. Bengore is composed of a series of distinct beds, some of which are formed of columns which, for symmetry, vie with architectural precision; while the rest present the most rugged and irregular aspect. At Fairhead the bed of greenstone is continuous from top to bottom, and at the same time presents the appearance of columnar disposition; but this, on close examination, is found to be only an appearance, arising from the natural disposition of the greenstone to separate into distinct prismatic concretions, totally destitute of that uniformity of shape preserved in each individual column at the Giant's Causeway. Such, however, is the tendency of the greenstone of Fairhead to assume this structure, that some masses of not more than 20 or 30 feet in diameter, and nearly 200 feet in length, may be observed almost entirely detached from the rest of the rock, and their having, in some instances, swerved a little from the perpendicular, hang in awful suspense over the abyss below.

The action of the great current, occasioned by the flowing of the tide through the Irish Channel, which disgorge itself just at this point, where it is again met by the wave of the Atlantic, occasions a never-ceasing eddy along the shore of Fairhead, which prevents any accumulation of matter; and were its base not protected by the enormous fragments of greenstone which lie scattered over it, the soft material on which the promontory is supported would soon be washed away, and the whole launched into the ocean.

Even as it is, the barrier formed by these enormous blocks is not entirely sufficient to resist the inroad of the waves. From time to time great masses of the rock fall with a tremendous crash upon the debris below. In 1810, a fall of this kind took place; and, from the appearance of the cliff, others may be constantly expected. Within a few feet, and parallel to the edge, there are several long deep rents, into which cattle have sometimes been known to fall, and which, in many places, may be plumbed to the depth of sixty or eighty feet; these can only be occasioned by the undermining of the cliff, as they do not occur excepting along its edge.

The greenstone of Fairhead is like all other beds of the same substance, very fine grained, resembling basalt on the upper and the under surfaces, and very coarse grained in the middle of the bed. This peculiarity is distinctly displayed on the under surface of the mass, where it comes in contact with the sandstone; but as no overlying strata occur immediately along the summit, it is only at some distance from it, that the fine grain is again observable. Fairhead dips a little west by south, and is overlaid by sandstone at the distance of about a mile from the sea.

According to Dubourdieu, a species of blindcoal, which promises to be a profitable return to the proprietors, has been found in the strata beneath the greenstone on both sides of Fairhead; and what is remarkable, he states that the blindcoal sells for 3s. per ton more than the blazing coal.

See the Rev. Mr Dubourdieu's Statistical Survey of Antrim; and Dr Hamilton's Letters on the County of Antrim. (s. n.)
FAIRY-RINGS, or Circles, is a name which has been given to spots or rings in grass fields, which are either bolder than the rest of the field, or covered with grass more green and more luxuriant. Sometimes they consist of a bare ring, seven or eight yards in diameter, forming a round path, about a foot broad, and having green grass in the middle, and sometimes of a circumference of green grass, including a circular portion covered with grass less luxuriant. Dr Priestley observed one about a yard in diameter, the ring itself being about a quarter of a yard broad, and equally so in the whole of its circumscription, but there was no appearance of any central spot.

FAIRY-RINGS, or rather segments of them, were observed upon Arthur’s Seat, near Edinburgh, in the year 1770, by Dr Ferguson, Dr Black, and Dr Hutton. They resembled the withered grass of a footpath, but they traversed the shoulder of the hill in such a direction, as to correspond neither to a sheep-track nor foot-path. On a nearer inspection, a narrow stripe of the grass appeared to be quite dead and withered. The breadth of the stripe was about nine, or in some places 12 inches; the sides of it were perfectly defined, without any gradation from green to withered grass, all the plants in the track being killed, without the contiguous part having suffered in the least. The length of the track was about 100 or 200 yards, “stretching from the south-east side of the southwest hill, through a hollow, and ascending obliquely the shoulder of the summit of Arthur’s Seat, on the south-east side.” Similar tracks of various extent were found in all the different aspects and situations, from the south side of the summit to the north side of the hill, half way down to the plain, but none at the bottom. Parallel to each of these tracks of withered grass, which appeared as if it had been made the year before, and was then black, from the grass having rotted, the distance of the old and new tracks was generally only a few inches. These tracks are not always continuous, but frequently separate. The tracks were not only always parallel and similar, but the very spots which composed them were similar, as if the one had been a copy of the other. The brown colour of the new track was visible at the distance of 200 or 300 feet; and even at a greater distance there could be seen another stripe of a dark green, which was some dark green grass that had grown among the rotten grass in the last year’s track. The greatest part, however, of the dark green was behind the last year’s track, and was owing to a similar growth of grass in places where the grass had been formerly killed or withered, and which were now almost covered with new plants, which gave a deeper shade of green than the rest of the hill.

Dr Hutton sometimes noticed five or six successions of tracks, but those which had been made above three or four years were much effaced. All the tracks were segments of large circles. From the observations which Dr Hutton made, it appeared that the “progress of the rings proceeded in the direction of a line drawn from the summit of the hill, intersecting the segment, that is to say, those portions of concentric circles are never inscribed, but always circumscribed; and for this reason it will appear that those circles of which segments are exhibited to our observation, must be increasing and not diminishing in their diameter.

“In the spring, about the middle of the month of April, the grass begins gradually to wither and decay. It is perfectly dead in a little time, that is, in a week or two, and then appears white or withered. Thus, every plant being killed in the new track, those vegetable bodies exposed to heat and moisture gradually decay, so as next year to exhibit a dark or black, instead of a light or white track, which it had been the year before; but, during the second year, the dead plants are still observed in the turf, which, as it begins to get new plants, loses gradually the appearance of the old ones, until at last little more can be observed than a broad shade of a much deeper green, which, on the one side, is compared with the natural verdure into which it sometimes seems gradually to terminate; whereas, on the other side, the deep green colour of the ground formerly tracked, is contrasted with the yellow or light colour of the withered grass.” After a careful examination of the appearances, Dr Hutton could think of no other mode of explaining them, than by supposing that they were produced either by lightning, or by the operation of insects.

Dr Price, Dr Darwin, and Mr Gough, without any plausible reason, ascribed these phenomena to lightning, but Dr Withering, with much more reason, accounted for their formation by the growth of fungi. He always found the spawn of the fungi below the brown and bare portion, by digging to the depth of two inches, whereas it was never found below those parts where the grass was green and luxuriant.

Dr Wollaston has examined the subject of fairy circles with his usual ingenuity and success. He observed that the fungi or mushrooms, first noticed by Withering, were found solely at the exterior margin of the dark ring of grass. The breadth of the ring, in that instance, measured from them towards the centre, was about 12 or 14 inches, while the exterior ring, occupied by the mushrooms, was only about four or five inches broad. Dr Wollaston conjectured, from the position of the mushrooms, that the rings were formed after the manner described by Dr Hutton, by a progressive increase from a centre, and this opinion was strengthened by finding that a second species of fungus presented a similar arrangement, with respect to the relative position of the ring and fungi, the fungi being always upon the external margin of a dark ring of grass. “I thought it not improbable,” says Dr Wollaston, “that the soil which had once contributed to the support of fungi might be so exhausted of some peculiar pantern necessary for their production, as to be rendered incapable of producing a second crop of that singular class of vegetables. The second year’s crop would consequently appear in a small ring surrounding the original centre of vegetation, and, at every succeeding year, the defect of nutrition on one side, would necessarily cause the new roots to extend themselves solely in the opposite direction, and would occasion the circles of fungi continually to proceed by annual enlargement from the centre outwards. An appearance of luxuriance of the grass would follow as a natural consequence, as the soil of an interior circle would always be enriched by the decayed roots of fungi of the preceding year’s growth.”

In opposition to the remark of Dr Withering, that he never could find any spawn of the fungi among the green grass, Dr Wollaston repeatedly observed undecayed spawn, even below the most luxuriant grass. “During the growth of the fungi, they so entirely absorb all nutriment from the soil beneath, that the herbage is for a while destroyed, and a ring appears, bare of grass, surrounding the dark ring. If a transverse section be made of the soil beneath the ring, at this time, the part
beneath the fungi appears paler than the soil on either side of it, but that which is beneath the interior circle of dark grass, is found, on the contrary, to be considerably darker than the general surrounding soil. But, in the course of a few weeks after the fungi have ceased to appear, the soil where they stood grows darker, and the grass soon vegetates again with peculiar vigour, so that I have seen the surface covered with dark grass, although the darkened soil has not exceeded half an inch in thickness, while that beneath has continued white with spawn, for about two inches in depth. The section of the space occupied by the white spawn, has, in general, nearly the same form, and may be compared to that of a wave, proceeding from the centre outwards, as its boundary on the inner side ascends obliquely towards the surface, while its exterior termination is nearly in a vertical position. The extent occupied by the spawn varies considerably, according to the season of the year, being greatest after the fungi have come to perfection, and is reduced to its smallest dimensions, and may, in some cases, not be discernible before the next year's crop begins to make its appearance.

For the purpose of observing the progress of various circles, I marked them three or four years in succession, by incisions of different forms, by which I could distinguish clearly the successive annual increase, and I found it to vary in different circles, from eight inches to as much as two feet. The broadest rings that I have seen, were those of the common mushroom, (ag. campestris); the narrowest are the most frequent, and are those of the champignon (ag. orenades of Dr. Withering). The mushroom accordingly makes circles of the largest diameter, but those of the champignon are most regular. There are, however, as many as three other fungi that exhibit the same mode of extension, and produce the same effect upon the herbage. These are the ag. terreus, ag. procerus, and the hygroderon boeista, the last of which is far more common than the two last-mentioned agarics.

There is one circumstance that may frequently be observed respecting these circles, which can satisfactorily be accounted for, according to the preceding hypothesis of the cause of their increase, and may be considered as a confirmation of its truth. Whenever two adjacent circles are found to interfere, they not only do not cross each other, but both circles are invariably obliterated between the points of contact; at least, in more than twenty cases, I have seen no instance to the contrary. The exhaustion occasioned by each, obstructs the progress of the other, and both are starved.

I think it also not unworthy of observation, that different species of fungi appear to require the same nutriment; for in a case of interference between one circle of puff balls and another of mushrooms, they did not intersect; but I cannot say positively that I have seen more than one instance.

I once found that a tree had interrupted the regular progress of a circle; but this appeared to be only a temporary impediment, as the extension had proceeded at the usual rate; and by passing obliquely from each side into the soil beyond the tree, had given the ring the form of a kidney, so that another year or two would probably reunite the two extremities into one curve surrounding the tree, being desirous of ascertaining in what length of time a soil might again recover the power of producing a fresh crop of fungi, I cut a groove, in one or two instances, along the diameter of a mushroom ring, and inserted a quantity of spawn taken from its circumference, with the hope of seeing it vegetate for some distance near the centre; but the experiment failed altogether, as I shortly after quitted my residence in the country.

Mr. Wilson ascribes fairy rings to the action of grubs, which are said to lie concealed under the ring among the roots of the herbage; and he supposes, that the fungi give a preference to these rings, on account of the abundance of dead vegetable matter to be found in them.

FAITH. See Theology.

FAITH, Confessions of: See Confessions.

FAKIR, or FAQIR, from the Arabic Fakar, signifying a poor person, is a kind of dervise, or religious beggar, very common in Eastern countries. They sometimes travel alone, or in troops of 200 or 300, having a superior, who is distinguished by his habit. The Fakirs never work, but subsist solely by the alms which they receive abundantly from the superstitious of the people. They go entirely naked, carrying on their shoulders a thick club, the end of which is wound round with rags of cloth of all colours. They strew their hair, which hangs half way down the back, with ashes, with which they sometimes besmeear their whole bodies. They are not allowed to marry. "They generally take up their abode," says Stavorinus, "in shady places, either in the open air, or in old and ruinous buildings, without using any thing to repose upon, or to cover themselves. Genuine Fakirs make vows that they will perform penance by remaining during their whole lives in some unnatural or uneasy posture, or by torturing their bodies by various methods; but most of them are not excited by real penitence or compunction, but are spurred on by vain glory, endeavouring to attract the notice and respect of the community, and thereby to raise themselves to esteem and honour. I met with several of them at different times. Among others, were some who, by keeping one arm stretched out upwards for many years, had lost the power of lowering it again, and were forced always to remain in that position. Others who had made choice of bending their body forwards, and who were in consequence grown so crooked, that they formed a right angle. Some who, by continually bending the head backwards, could not bring it back to its natural position. There were others, again, who dragged heavy iron chains about with them during their whole lives." In another part of his voyages, Stavorinus informs us, that he met with the ruins of a stone building in which a Fakir had taken up his residence. He sat entirely naked, by a slow fire, in the middle of the ashes. His long and black hair was cloathed with ashes and dirt, and he had imposed upon himself the horrid penance of thrusting through the glans of the penis a brass ring, of about the thickness of a quill, and three inches in diameter. The Bengalese women think that sterility may be cured by a particular species of devotion to this disgusting object. Besides this ring, Stavorinus observed three other riveted iron rings link-
ed to it, which might weigh altogether about 2½ pounds. When the Fakir walked, the whole of these rings hung loose, without seeming in the least degree to incom-
mode him.

Stavorinus describes another Fakir at Surat, who had imposed upon himself a silence of twelve years, ten years of which he had already elapsed. He was about 30 years old, and well made. He was covered with a white dust, made of the ashes of burnt cow-dung, and his hair and beard were filled with that dust. In the large hut where he resided, there was a niche oppo-
tive to where he sat, which contained an image three feet high, carved out of one piece of a black shining stone, and representing a man in armour, with four arms. The Gentoo paid the greatest respect to this Fakir.

It would be a waste of time to give an account of the various tortures by which these Fakirs seek for re-
putation. Tavernier informs us, that some of them never sit or lie down to sleep, but support themselves by a rope hung down for that purpose. Others lay fire on their heads, and burn their scalps to the very bone; others roll themselves naked on thorns, while some bury themselves in a pit or ditch for nine or ten days, without tasting food or drink. D’Herbelot rec-
ons that there are about 800,000 Mahometan Fakirs, and 1,200,000 idolatrous ones in the Indies. See Ta-
vrier’s ‘Travels,’ and Stavorinus’ ‘Journey to the East Indies,’ vol. i. p. 139, 142; and vol. iii. p. 147. (j)

PALCO. See Ornithology.

FALCONER, William, an ingenious poet, of obscure parentage, of whom little more is known than his genius and his misfortunes. He was a native of Scotland, and is supposed to have been born in one of the villages on the coast of Fife; but his parents, in con-
sequence of some domestic misfortunes, removed to a sea-port town in England, where they both died of an epidemical disorder, leaving their son, an orphan, in destitute circumstances. Having been bred to the sea, he spent the greatest part of his life upon that element, in very subordinate stations. In such unfavourable circumstances, it is difficult to conceive how he could have found leisure, means, or opportunity, for acquiring that knowledge and taste, and for culti-
vating those poetical talents, which he afterwards so conspicuously displayed. On this subject, the scanty memoirs of his busy and obscure life, afford us little or no information; and we are left to conclude, that Fal-
coner possessed one of those ardent and vigorous minds which seem destined to surmount every obstacle op-
bosed by adversity, and to rise into eminence by their own natural elasticity. The late ingenious editor of the works of Burns, however, informs us, that Falconer, while serving on board a man of war, attracted the notice of Campbell, the author of Lxiesanes, who engaged him as his servant, and having discovered his talents, took pleasure in promoting his instruction.

In the year 1751, he published, at Edinburgh, A Poem, Sacred to the Memory of Frederick Prince of Wales, which displayed considerable powers of versi-
fication, but attracted little notice. In 1762, appeared The Shipwreck, a Poem, in three Cantos, by a Sailor; a production which has insured to Falconer an eminent rank among the British poets. This poem, which is founded on real incidents, commemorates the principal occurrences during a voyage from Alexandria to Venice, in which, having suffered shipwreck, the author escaped with only two others of the crew. It was in-
scribed to Edward Duke of York, brother to his pre-
sent Majesty, and was very favourably received by the public.

Through the influence of his royal patron, whom he further complimented by “An Ode on his se-
cond departure from England as Rear Admiral,” Falconer obtained the lucrative situation of pursuer of the Royal George, one of the finest ships in the British navy. It was probably from motives of gratitude, that he was now induced to enter the field of political contro-
versy; and having enlisted under the banners of the party of “King’s Friends,” he published a satiri-
ical piece, entitled, “The Demagogue,” in which he

inveighed against Mr Pitt, (afterwards Earl of Chat-
ham), and his adherents.

In 1764, he gave a second edition of the Shipwreck, with considerable additions, having extended it to the length of about one thousand lines more than the former. In 1769, he published “The Marine Dictionary,” in one volume 4to; a work of considerable utility; and, about the same time, he gave a third edition of the Shipwreck, with some alterations.

Towards the close of the year 1769, he embarked, with several East India supercargoes, on board the Aurora frigate, with the view of endeavouring to improve his fortune abroad. This vessel, however, was never heard of after her departure from the Cape of Good Hope, in the month of December; and there is no certainty that she must have foundered at sea, and gone down with all her crew.

The title of Falconer to the name of a poet, is suf-
ciently established by his Shipwreck. The subject was new, and eminently capable of poetical effect; and the poem derived additional interest from the reality of the incidents which it described. The professional knowl-
edge and poetical powers of the author, enabled him to do ample justice to his theme; and the originality, paths, and melodious versification of the Shipwreck, have secured for it a place among the standard and po-
lar productions of the British muse. (2)

FALKIRK.
FALKIRK.

by the vast population of the district, taken in connection with the ships and vessels passing to and fro, give the whole scene an air of grandeur and activity, seldom to be met with, but in the neighbourhood of large commercial towns.

When Falkirk is viewed from the north, it is seen at a great distance, and is conspicuous for an old tower connected with the church, and an elegant spire 140 feet high, lately erected in the middle of the town. This view of Falkirk is grand, on account of the bold risings of the ground behind it; and seen from the north-west, it is particularly striking by the Callander wood, or part of the ancient forest of Caledonia, which forms the back ground.

The situation of this town is no less healthy than beautiful, and it is well supplied with water, which is conveyed to it by pipes. Standing on an eminence, it has a free circulation of air; and having a declivity on every side, it is easily kept dry and comfortable. The houses are, in general, well built, and though it has risen to consideration without a plan, yet it is more regular than might have been expected. It consists of several streets and lanes; and the principal one, though narrow toward both ends, where the ports were formerly situated, yet upon the whole it is commodious and regular. The inhabitants of the town may be reckoned about 4000 persons. The population of the parish is about 10,000, and includes the thriving port of Grangemouth, which is the opening from the Frith and eastern seas into the great canal.

That port has lately been favoured with the establishment of a custom-house; and the revenue received at that office for the last quarter has been stated at £30,000, and the preceding one not much less. But these sums far exceed any former receipts, and are chiefly to be ascribed to the prodigious number of vessels pouring into that harbour, after so long a stagnation of trade, by the inconveniences of a protracted warfare. But though such returns of revenue are not to be expected in continuance, yet Grangemouth is a thriving village, and is likely to rise in importance.

Police.

Justice of the peace courts are regularly held in Falkirk, and also occasionally other meetings respecting the turnpike roads, or the particular business of that quarter of the shire. It is the market town of a population not less than 25,000 persons; and yet there is not a magistrate in the town, nor a place of confinement where a culprit may be shut up for a single hour. In these circumstances disorders occasionally ensue, as must frequently be the case in populous districts; but instances of violence and outrage are exceedingly rare; and the general deportment of the people shows their quiet and peaceable disposition.

Falkirk was formerly a borough of regality; and the different trades had acquired certain privileges and immunities; and the office of the stint-masters is a residue of the powers which the burgesses formerly acquired. When the feudal jurisdictions were taken away, after the rebellion of the year 1745, Falkirk was converted into a burgh of barony; but a baron bailie is seldom appointed, and the town is thus deprived of the protection which he might afford.

While Falkirk was a borough of regality, it was furnished with a jail and court-house by the noble family of Callander; but after the honours and possessions of that family were forfeited, they were suffered to fall into ruins, and the site and materials being sold, the whole is now converted to another purpose. The general advantage of a place of confinement in a populous situation like this has long been felt, and there are now measures pursuing, for having a lock-up house, or a place of confinement, legally established in Falkirk. It has also been proposed to have a sheriff-substitute appointed; but as this project would probably meet with resistance, it would perhaps be more expedient to have a police bill for the town and parish of Falkirk, investing the bailies thereof with powers to act as justices of the peace for the county of Stirling, which would afford ample means of order and protection.

Falkirk being 24 miles from Edinburgh, and not much less distant from Glasgow, has advantages in point of trade, which towns that are nearer those large cities do not enjoy. Though there is no species of manufacture carried on but for the use of the country, unless it be some trifling branches of the cotton trade, together with leather and shoes, it is but occasionally that the people of this district purchase from Glasgow or Edinburgh, and therefore the shops of Falkirk are well provided with the conveniences as well as the necessaries of life. It has long been noted for one of the best butcher meat markets in the country. But as there are no magistrates, and few means of public improvement, there are no shades, nor proper market-house, for exposing it to sale.

The same want of accommodation is severely felt by the farmers, who bring their grain to market on the Thursdays. Falkirk has its full proportion of fairs, and there are three thrstes, or great cattle markets, which are held in its neighbourhood on the second Tuesday of August, the second Tuesday of September, and the second Tuesday of October annually. These are more numerously attended, and more business is done in buying and selling cattle and sheep, than at any other similar markets in the kingdom. A few horses also are bought and sold.

Being the centre of so numerous a population, there is a great variety of dissenting chapels in Falkirk, but none of the episcopal persuasion. There is only one parish church, and one minister of the establishment. The church is large, and was built a few years ago after the Gothic form, according to a plan by Mr Gillespie; but it has no pillars nor arches in the inside. Falkirk was of great consideration in ancient times; and the parishes of Denny and Monivaird were pended to it. In the year 1724, a portion of the parish of Falkirk was erected into a parish, and denominated Polmont. A considerable part of it was at the same time added to Hannon and Cumbernauld. Reg. Mag. Sig. Edin.

It appears that the church of Falkirk had been founded by Malcolm Canmore, one of the kings of Scotland, A.D. 1057. The property and right of presentation belonged to the archbishop and chapter of St Andrews, till that religious body conveyed them to the monastery of Holyroodhouse in the year 1166. That celebrated convent was founded by King David in the year 1128, and if not the first, was one of the earliest in Scotland. Consistent with the credulity of the times, the reason assigned for its erection was a vision, which was said to be seen by the king in a moment of danger while he was hunting; and on the spot where the vision appeared the monastery was built.

It was called the Abbey of the Holyrood, because history upon that festival day the supernatural appearance was seen, and because the stag, which seemed to attack and
thrust the life of the king, vanished from his sight, and left the semblance of a cross. In memory of this occurrence, a black cross was deposited in the monastery, and being supposed to have a powerful influence in times of emergency, King David Bruce wore and lost it at the battle of Durham, upon the 17th of October 1346. The monks of Holyrood-house belonged to the order of St Augustine, and were lodged in the castle of Edinburgh, till the monastery was ready for their reception, to the exclusion of the nuns, who had hitherto resided in that part of the castle. Several charters of Malcolm IV. are dated from the monastery, Sancta crucis de castello quiellarum. * See Diplomat. vet. Advoc. Lib. vol. i. p. 292, et 294.

The abbey of Holyroodhouse acquired lands from the kings of Scotland, and picus subjects, till it became exceedingly rich, and had estates in the counties of Edinburgh, Linlithgow, Stirling, and Peebles, together with churches in various other parts of Scotland. The power of the Popish adherents had long been on the decline; and, while the affairs of the nation were unsettled, the rich endowments of the church were obtained by friends and favourites of the crown. Adam Bothwell, bishop of Orkney, acquired the possessions of Holyroodhouse, in the year 1582, perhaps in commendam; and in A.D. 1587, with the consent of the convent, they were given in feu farm to Sir John Ballenden of Auchnoul, Lord Justice Clerk.

John, Lord Bothwell, son of the Bishop of Orkney, succeeded his father as commissary of Holyroodhouse, and he, with consent of the surviving members of the monastery, (for the fraternity were much diminished in number, and none being permitted to enter,) were prevailed upon, for certain considerations, to surrender the whole of the property of that monastery into the hands of the king; and it was granted in full farm and absolute property, to Sir Lewis Ballenden, son of Sir John, and called the barony of Broughton. On the death of Sir Lewis in the year 1591, the property devolved upon Sir James, his son, who conveyed a part of it, the barony of Abbots-kers, in A.D. 1596, to his kinsman, the seventh Lord Livingston, and the first Earl of Linlithgow. The barony of Abbots-kers comprehended the greater part of the old parish of Falkirk, before Polmont and other parts were separated from it. It included also other lands and possessions in the county of Stirling; but though the barony of Abbots-kers was conveyed to the family of Callander, yet considerable parts of it were disposed of to other persons, by the family of Ballenden.

The town of Falkirk appears to have had its beginning under the protection of Holyroodhouse, and the oldest part of it was erected in the vicinity of the church. The Livingstones of Callander having acquired property, at an early period, in what were called the lands of Falkirk, encouraged building, and extended the town. When the abbots' property was added to the barony of Callander, that noble and munificent family cherished the town, and secured the affections of the inhabitants, till their titles and possessions were forfeited, for the support which they gave, in the year 1715, to the claims and pretensions of the Stuart family, from whom they had received their honours, and the most of their wealth.

Falkirk was formerly denominated Ecclesbreae, and perhaps it was so denominated by being situated upon an eminence, when few or no houses were near it. The name of Falkirk seems to have been of a later date, and was probably derived from the Latin word Vallum, a wall or rampart, and the Scotch word kirk, meaning the church upon the wall, for in truth the Roman wall, or Graham's dyke, ran along the south side of the town, and even through the ground on which a part of it is built. One of its more early names seems to have been Eglisbrea, which is a Gaelic denomination, signifying the spotted church; and, in conformity to this, in ancient writings and charters, it is called Varia Sacellum, or more commonly, Varia Capella. In the charter of the Archbishops and chapter of St Andrews, to the convent of Holyroodhouse, A.D. 1166, it is denominated Eglisbrea, and Varia Capella. It is only in subsequent times and documents that we hear of Falkirk.

Falkirk being on the boundary between the Caledonian and Roman possessions, was the scene of many sanguinary conflicts; and at Camelon, in the immediate neighbourhood, there was a Roman station of some note. About the beginning of the 5th century, while the Caledonians, under the conduct of Robert Graham, a friend or connection of King Fergus II. were repelling some incursions of the Roman forces, the gallant Graham lost his life; and from the eminence of his character, the Roman wall of Severus, or as most will now have it, of Antoninus, was from that time known by the name of Graham's dyke.

When the south aisle of the old church of Falkirk was lately taken down, a small piece of marble was found with the following inscription in barbarous Latin:

FVNERATVS
HIC . DEYN
ROB . GRAHAM
ILLE . EVERSUS
VALL . SEVERUS
AC . LIS
FEROVSIVS . IL
R . SCO.

This inscription, like many others, must have been made long after the event, but it shews, that Graham was buried in the church-yard of Falkirk, and it appears from the inscription, that the Roman wall that runs from the Forth to the Clyde, was at one time called the wall of Severus.

Toward the end of the 13th century, a severe battle was fought between the army of King Edward of England and the Scottish forces, upon the plain below Falkirk, and scarcely half a mile distant from the town. Among the Scottish troops were Sir John de Graham, Sir John Stuart, Cumyn, and Wallace the celebrated champion of Scotland. That there might be some jealousy among those illustrious generals, is not inconsistent with the infirmities of human nature; but it is not ascertained, on good authority, that the fortune of the day was injured by any fault of theirs, (Dunrump. Annal) notwithstanding the different opinion

* * * David Rex Scottis templum et monasterium longe magisddentium fundavit canonicis regularibus, A.D. 1128, in suburbis Edinburghi. Ubi die festo vestantis, percutuus a cervo duo corna comprehenderet, erat imaginem non cervi corna vidit, codenque loco cernbium exerit. Diplomat. vet. Advoc. Lib. vol. i. p. 278, 280.*
which some historians have expressed; but upon that memorable day, De Graham and Stuart were killed in battle, and both of them were buried in the church-yard of Falkirk. Till of late the grave of Sir John Stuart was only distinguished by a stone, shaped like a coffin, and without a name; but now his name and date are inscribed upon the stone. Sir John de Graham's was originally marked by a sculptured figure in human form. At three different times, stones supported by pillars, were placed over his grave; one above another, by the care of relations, namesakes, or friends, and the last was erected by William Graham, of Airith, Esq. A. D. 1773.

In the beginning of the year 1746, a battle, or rather skirmish, was fought between the king's forces and the Highland troops, in the interest of the Stuart family. The king's forces were routed, and fled toward Linlithgow; the Highlanders took possession of the town of Falkirk, and conducted themselves with a considerable degree of order and moderation, though they knew that the people in general were hostile to their views. A monument was erected in the church-yard of Falkirk, over the bodies of the Sir Robert Monro, bart. of Foulis, and his brother the Doctor, who were both killed in the field of battle.

The Callander estates, after the forfeiture of that noble family, were sold to the York Buildings Company; and when their affairs had run into disorder, they were exposed to sale by the authority of the Court of Session, and purchased by William Forbes, Esq., a native of Aberdeen, who is the present proprietor. (J. W.)

FALKLAND ISLANDS, a group of islands in the Atlantic Ocean, situated at the utmost extremity of South America, and about 80 leagues from the Straits of Magellan. Two of them are of considerable extent, being more than 70 leagues in circumference; and lie between 51° 10' and 52° 34' South Latitude, and between 55° and 62° West Longitude. These islands were first seen by Captain Davis, who sailed under Sir Thomas Cavendish in 1592; next by Sir Richard Hawkins in 1594, who called them Hawkins's Mainland, in honour of Queen Elizabeth; in the year 1598, by Sebald de Wurt, who named them Sebald's isles, and they are so designated in all the Dutch charts; in 1653, by Dampher, and probably about the same time by Cowley; in 1689, by Strong, who gave them their present appellation in honour of Viscount Falkland; in 1699, by a Frenchman named Beauchesne Gouin; and in 1721, by Raggewin, a Mecklenburgher in the Dutch service, who circumnavigated the whole group, and called it Belgia Australis. The Dutch mistaking the numerous capes for portions of different islands, gave to the whole the designation of New Islands; the French, generally call them Malouines from the people of St. Malo, whom they wish to consider as the first discoverers.

The navigators of the last mentioned nation were, without question, the first settlers on these islands, when their government, after the loss of Canada, in 1763, selected them as a new American settlement, particularly as a place of shelter and refreshment for vessels bound to the South Sea. A colony of Acadian families, above twenty-seven persons in all, was carried thither in 1764, by Commodore Bougainville; and in the following year, by the addition of new colonists, the number of inhabitants amounted to about 150. In the beginning also of the year 1765, Commodore Byron, in conformity to his instructions, took possession of these islands in the name of his Britannic Majesty; and a British colony was settled, the year after, in Port Egmont, by Captain Macbride, who circumnavigated the whole coast. But they were soon found to be of very little value, particularly from the total want of wood; and first the French closed their settlement to the Spaniards in 1707, and the English abandoned theirs in 1778. They are now employed by the Spaniards as a receptacle for criminals from their American dominions.

The two largest of these islands are separated by a channel about twelve leagues in length, and one to three in breadth; and were furnished with the most secure and capacious harbours. Port Egmont, on the north-west coast of the largest island, is described by Byron, as one of the finest havens in the world, and as capable of containing the whole British navy in perfect security. The general aspect of the coast is rocky and desolate; and no kind of wood has been found on any part of the islands. They appeared to the first navigators, while sailing along the shores, to be completely covered with trees; but these, upon a nearer approach, were discovered to be nothing but bushes of tall rushes and reeds, which grow in clusters to the height of three feet, and then shoot out other stalks about six or seven feet in length. The higher lands are covered with heath, and there is great abundance of excellent turf for fuel, capable even of supplying sufficient heat to a forge. There is no appearance whatever of those islands having ever been inhabited previous to their discovery by Europeans; and the navigators, who first landed upon their shores, found the animals so unacquainted with man, that the birds suffered themselves to be taken within the hand, and even settled upon the heads of the people when they stood still. The surface is marshy, and the soil is composed first of a thick turf, then a black mould, from eight to twelve inches deep, and next a yellowish clay, resting upon strata of slate and stone. In most places on the coast is stone fit for building; and, in the interior, there is earth capable of being manufactured into bricks and potter's ware. The rocks are chiefly of quartz, with some pyrites, and marks of copper. Red and grey slate, and different kinds of ochre, are common; but no mines or metals have been discovered. The climate is temperate and salubrious, free from the extremes of heat or cold; but there are frequent rains and stormy winds in all seasons of the year. The running streams are never frozen; and the ice on the lakes and pools is seldom sufficiently strong to bear the weight of a man, above twenty-four hours in succession. Snow remains upon the tops of the highest mountains about two months in winter; but seldom above a day or two in the lower grounds. The hoar frosts in spring and autumn occasion no injury to the plants, but, being chased away by the sun, are converted into a refreshing dew. Thunder is seldom heard in summer; but, even during that season of the year, the winds are almost uniformly violent; and, from the want of fuel and shelter, all the settlers have suffered greatly from cold. A remarkable peculiarity has been observed in the tides, which do not rise at settled periods subject to calculation; but just before high water, the sea, in less than a quarter of an hour, rises and falls three times, as if shaken up and down, and this motion is always more violent during the solstices, equinoxes, and full moons. The surface of the ground is partially covered with turf, shrubs, productions, and a variety of plants. The turf, which is found chiefly above the clay soil, is formed of the roots and
remains of plants in marshy situations, and is frequently seen in strata of considerable thickness. The meadows, which are of great extent, and watered with numerous rivulets from the hills, afford abundance of excellent pasturage. One of the most common grasses grows to the height of six feet, and furnished the colonists with an excellent thatch for their houses, while its stalk, which was very sweet and nourishing, was preferred by the cattle to every other kind of food. The resinous gum plant is the most conspicuous and curious of the vegetable productions. It is of a bright green colour; but, having neither stalk, branches, nor leaves, it is more like an excrecence from the earth than a plant. It is only about a foot and a half in height, but frequently more than six feet in diameter; and so firm in its texture, as to bear the weight of a man without yielding to the pressure. On its surface are drops of a tough yellowish matter, about the size of pease, resembling resin, and of a strong aromatic smell like turpentine. A small shrub, creeping close to the ground, was discovered to possess the taste of spice fir; and, being made into beer with molasses, proved a powerful antiscorbutic. Here are great quantities also of wild parsley, wood-sorrel, and watercresses, which provide a valuable relief to those who are afflicted with the scurvy. The only fruits found upon these islands, capable of being used as food, are a small berry about the size of a pea, resembling the lucet of North America, and another similar to the mulberry, both of which grow upon creeping plants. Among numerous flowers, only one appeared to yield any perfume, and its smell resembled that of the tuberose. The shores are covered with sea-weeds so strong and thick as almost to prevent the landing of a boat. The tides throw up several corals, the finest mother-of-pearl, sponges of the most compact texture and delicate fibre, and a variety of shells, of which the most curious is a bivalve called la poulette, said to be found no where else except in a fossil state. Only one species of quadruped was observed on these islands, called the wolf-fox, from its resemblance to both these animals. It is about the size of a common shepherd's dog, with very long sharp fangs; and barks in the same manner, but not so loud. It digs a kennel under ground, and preys upon the wild fowls and seal. Great numbers of these animals were seen by Byron, who describes them as remarkably fierce, running even from a great distance, to attack the sailors, and plunging into the sea after the boats. The coasts abound with seals and walrusses or sea-lions, many of which are of an enormous size, and also very formidable from their ferocity and strength. Land and water fowls are found in great numbers and variety. The most remarkable are swans with necks of a velvet black colour, flesh-coloured feet, and white bodies; wild-geese, one species of which, similar to the Canada goose, feeds chiefly on dry land, and affords a wholesome and palatable food; ducks and teal, resembling those of Europe; a species of grebe, of the most beautiful plumage, and eyes like rubies, surrounded with a circle of white feathers; a kind of guillemot, whose flesh is very good to eat, and which the colonists destroyed in great quantities, merely with sticks in their hands; a species of penguin, distinguished by its statelier gait, its beautiful plumage, and solitary habits; different kinds of petrels, small eagles, falcons, owls, snipes, curlews, herons, thrushes, &c. There were few kinds of fish taken by the settlers and navigators, but the most common were mullet, gadem, sardine, transparent pike, and a fresh water trout of a green colour, without scales. There is no want of muscles, cray-fish, crabs, shrimps, and other small fish; but they were found very inferior to those of Europe in taste. See Byron's Voyage round the World in 1766, &c. Bougainville's Voyage in 1766; Perceval's History of a Voyage to the Moluquines. (g)

FALMOUTH, a sea-port town of England in Cornwall, of modern erection, its charter being granted by Charles II, in 1661. Its rise and increase has been altogether owing to the progress of commerce, and particularly to the establishment of packet boats for America, the West Indies, Spain, Portugal, Brazil, &c. Its harbour is accounted the finest in England, next to Plymouth and Milford Haven, and being land-locked, it affords complete protection in tempestuous weather. The town, situated at the bottom of an eminence which commands the harbour, consists of one street, nearly a mile in length, extending along the side of the beach. The pilchard trade is an object of considerable importance to this as well as to other parts of Cornwall. Pendennis castle, a building of much older date than the town of Falmouth, stands on a lofty rock, joined to the main-land by a narrow neck, and defends the west entrance into the harbour. The rock is three hundred feet above the sea, and appears to rise from the bay like an island. This fortification was begun by Henry VIII, and improved in some measure by Elizabeth, but more by Oliver Cromwell, having been much damaged during the civil war. It is now modernized, and mounted with seventy pieces of cannon. St Mawe's castle is a much smaller and less remarkable erection, standing on the eastern side of Falmouth harbour, and tracing its origin likewise to Henry VIII. The houses in the neighbourhood, though few in number, constitute a Cornish borough, while Falmouth, in consequence of its comparative recency of growth, is unrepresented in parliament.

Outside of Falmouth harbour there is a safe and commodious roadstead for vessels of the largest size. It is the opinion of many naval men, that the value of Falmouth, as a seaport, is not yet fully known. Its great advantage lies in its easy access to the Western Ocean, the difficulty of which from Portsmouth, and even from Plymouth, is experienced every season by our outward bound vessels. Now from Falmouth the distance to the Lands-end is less than from the Thames to the south Foreland; there are neither shoals nor sand banks by the way, and it is highly important to consider, that the French side of the Channel terminates on the meridian of Falmouth, so that if a vessel going from that port gains a league of westing in her southward progress, she is forthwith received by the ocean. Were the wind to get round to the westward the day after her leaving Falmouth, the vessel has still a clear course of more than four hundred miles to the southward before meeting with land, viz. the north-east coast of Spain. The difficulty of getting into the ocean from Portsmouth or Plymouth, will be apparent on computing the small number of days in the year during which the wind is fair to come down the Channel. On examining a diary, we shall find that sixty or seventy days in the twelve-month are rather above than below the average. In 1608 the expedition under Sir David Baird sailed from

Birds.

Fish.
Fanton

FANTIN is the name of a county in the west of Africa, which extends about 30 miles along the gold coast. The capital, which is also called Fantin, is about twelve miles from the coast. Fruits, maize, and palm wine, are produced in abundance. There are numerous small towns on the coast, which are inhabited by about 4000 fishermen. The principal towns and villages are Anamaboa, or Anamabou, where the English have a fort; Adjia, or Aga; Great and Little Cormantin, or Kormentin; Agua, Laguyo, Fantim, Guele, and Maufran. See Anamabor, and Labarthe's Voyage a la Coté de Guinée, Lett. viii. p. 69. Paris, 1803. (w)

FAOUÉ, or Fouâ, is the name of a town of Egypt, situated on the west branch of the Nile, and about 20 miles from the sea. It was formerly a large and flourishing city, and contained several commercial establishments belonging to Europeans. The ancient edifices, however, are now in a state of ruin, and the place is falling rapidly into decay. It is supposed by some to be the Memphis, and by others the Naukratis, of the ancients. The surrounding country is rich, and the gardens produce fine fruit, which is held in great estimation. East Long. 31°, North Lat. 51° 10'. See Lord Valentia's Travels, vol iii. p. 443. (w)

FARE. See Drama.

FAREHAM, a market-town of England in Hampshire, is situated at the north-west extremity of Portsmouth harbour. The houses are tolerably well built. There are two meeting-houses and one church, which stands at the entrance to the town. The inhabitants are principally employed in the manufacture of sackings, and ropes for shipping, of which they send great quantities to the dock-yard at Portsmouth. In the summer season, this town is much frequented as a bathing-place; a commodious bathing-house has been lately erected. Vessels of considerable burthen are built at the quay. There is here a good market on Wednesday, and an annual fair on the 29th of June, which is supplied with corn, cheese, hops, &c. The town also carries on a considerable coal-trade. The following is the statistical abstract for the town and parish, in 1811:

Inhabited houses, 596
Families that occupy them, 698
Do. employed in agriculture, 255
Do. in trades and manufactures, 179
Males, 1392
Females, 1733
Total population in 1811, 3825

See Beauties of England and Wales, vol vi. p. 308. (w)
Farey's Equal Temperament of the Musical Scale.

The apparent simplicity of the Isotonic Scale, wherein the octave is supposed to be divided into 12 exactly equal semitones, and its agreement with the vulgar notions of our musical notation, have occasioned an unusual number of theoretical writers to give their opinions in favor of this system: the names of more than 20 such authors are before us, many of whose recommendations of it are most unqualified: yet few of them have been at the least pains to inquire as to the harmoniousness of its concords, or otherwise; leaving these to be inferred from its semitones, which are discordant—the length of string calculated for sounding each note, having usually been thought sufficiently to inform the musical student: at the same time it has been, and may fairly yet be questioned, whether this system has, in one single instance, been actually tuned on an instrument, with sufficient accuracy for judging fairly of its practical effects in performance.

It was for removing this defect of information, as to a scale so simple and elementary as the Isotonic, that the gentleman whose name appears at the head of this article was induced to pay considerable attention to a system, which he was convinced was at best but a most violent and unnatural simplification of a subject vastly more profound and extended, as Mr Overend has already proved, in his admirable essay on Perfect Intonation: and it was in the course of this investigation, that Mr Farey discovered a new regularly tempered system, having its fifth $G \# \neq E \flat$, less than each of its other eleven equal fifths, by which Mr Overend has denominated the most minute (m), the last interval that he or any other person has yet discovered, and being in sensible, perhaps, in the nicest experiments in harmonics. None of its semitones differ from each other more than this very small quantity, 0.000001; and the whole of them have finite and determinate ratios, expressible by help of the primes 2, 3, and 5; and, lastly, each of its notes may actually be tuned (on an organ having a sufficient number of pipes, like the Euharmonic organ of Liston) by the means of untempered or perfect concords.

Notes: Tunable Intervals, 4, 3, 2, 1 lengths of strings.

Flats 3rds, Sharp 11ths, Sharp 4ths, Flat 7ths, Flat 6ths, Sharp 7ths.

- Even Dr Robert Smith has bestowed too little attention on this much recommended system, contenting himself with mentioning, (Harmonies, 2d edit. p. 160), that its harmony "is extremely coarse and disagreeable," and has, at p. 167, erroneously stated the temperatures of its V, VI, and III, to be 1-10th, 7-10ths, and 6-10ths of a comma, instead of 1-11th, 8-11ths, and 7-11ths, respectively, which temperaments may nevertheless be very nearly obtained, from his col. I. of Table II. in p. 158, viz. 7-10ths, 6-10ths, and 5-10ths, instead of 7-12ths, 6-17ths, and 5-17ths, as above.

† The asterisk reversed, or at the bottom of the line, is here, and will hereafter be used, to denote the full of the interval ephemeris or vol. ix. part I.
The 1st, 2d, 4th, and 5th, of the above columns, seem to require no explanation. The numbers in the 1st, 2d, and 3d range of col. 3, shew how many Vths, 4ths, or 11ths, respectively, are to be tuned upwards, and the numbers with affixed, of the same intervals, are to be tuned downwards respectively from tenor cliff C, in order to produce each several note.

The numbers in the 6th to the 11th columns, (calculated by our 4th Theorem in the article Beasts,) shew the number of beats in a second of time, made by each several concord, 3d, 11d, 4th, Vth, 6th and Vth, above the note on the same line in col. 1, either flat or sharp bestings, as is marked at the bottom of the column: and hereon it may be proper to remark, that the beats on all the Vths above D, are repetitions of those of their complementary 3ds from C to G½, and the remaining beats from C to D are the halves of those of their complementary 3ds; also the beats of the 6ths below E, are the same as those of the IIIds from C to G½, and the remainder are double of those of their complementary IIIds; and the beats of the 4ths from C to F½ are the same as their complementary Vths from F to c, and the remainder are double of their complementary Vths respectively.

In order to shew, in different ways, the extremely near agreement of the above system with the Isotonic, (which agree in col. 2), it may be proper to state, that in lengths of strings, the greatest difference (on G½) is but .00037, and the mean of all the differences only .00017; that in the vibrations, the greatest difference (on G½) is .0022, and the mean difference only .0005. With respect to the beats, which offer by far the most accurate mode of judging of the practical effects of any two systems, it may be proper to compare together the sums of the beats of each concord, in each system, as follows, viz.

—by which, the very insensible differences of these two equal temperaments will sufficiently appear; the beats differing but 1 in 50, in the most extreme case, the 6th or By. (a)

FARY's NOTATION OF MUSICAL INTERVALS. This new mode of expressing the magnitudes of intervals having been adopted in our work, it may be proper to say a few words in this place on the discovery of this notation. The late Mr. Marmaduke Overend, organist of Isleworth Church, near London, and author of "a brief account of, and an introduction to, Eight Lectures in the Science of Music, (intended) to be read," &c. 4to. pp. 180. Payne & Son, 1781, bestowed inconceivable pains and labour on the calculations and comparison of musical intervals, by actual involutions, multiplications, &c. of the terms of their ratios, never using logarithms, and but rarely resorting to the indices of the component primes, for shortening his work: he adopted a consistent nomenclature throughout, according to which he named the several intervals, and fixed on a symbol or character for each, as we have done in our 30th Plate in Vol. II. and throughout our work.

At the conclusion of each of his arithmetical calculations, as above, Mr Overend was careful to express his results in form of equations, by means of his symbols, and to transcribe the whole neatly into thick quarto volumes. After Mr Overend's death, Dr John Wall Calcott, one of the most able but unfortunate of musicians, having purchased all Mr Overend's manuscripts from his family, kindly offered the use of the above mentioned quarto volumes to Mr Fary, with permission to make all such extracts from, and use of their contents, as he might be able. In perusing 14 of these volumes, in June 1807, Mr Fary found an immense number of intervals correctly deduced by Mr Overend, and expressed in his symbols, which no previous writers had noticed, the whole of which he was desirous of preserving, in an arranged Table; but previous to this, it became necessary to reduce them all to some one notation; a thing which never seemed to have occurred to Mr Overend, but who in each instance left his intervals expressed, in the symbols of those particular intervals, which he happened to have used in calculating their ratios.

In order to avoid negative signs, which are indispensable in the use of such large intervals as S, t, and T, the smallest that any writer had previously used as the terms of their notations, it occurred to Mr Fary to select the three smallest intervals that Mr Overend had discovered, viz. d, f and m; but this notation, as well as that by E, f and m, proving to have negative signs to m, in every instance, as remarked in our article COMMON MEASURES of Musical Intervals, he next tried #, f and m, which has been found in its most extended use, the best adapted by far than any others of the numerous ones subsequently tried, for a general notation of musical intervals; and, as such, we have in our work adopted and used it.

The methods by which Mr Fary at first deduced the expression for each interval # in his notation, from the multiform ones of Mr Overend, were far from the most direct or easy; but, assuming the notes of the common chord, III, V, and VII, to be known to be 107 ½± 4 f ± 17 m, 38 ½± 7 f ± 31 m, and 612 ½± 12 f± 53 m, respectively, as may easily be proved to be true, by either the indices of the primes, or the logarithms of these intervals, in our Table, Plate XXX. Vol. II. by adding together 197 times #, 4 times f, and 17 times m, and so of the others, the following resolutions and compositions would readily give us his expressions for all the intervals in the Table; thus,

(a) 275 (to be read "fall schema,") and the asterisk in its usual position *, to denote the rise of a schema, (to be read "rise schema"); to the asterisk and grave united, *_, will denote the fall of a minor somma or C, and *• the rise of the same interval; and, in like manner, * will denote the rise of the dischisma or G, and *• the fall of the same interval, attached either to the literal or the numerical marks of intervals. See NOTATION of Musical Intervals.

And he marked the same in the table, in pencil, in Mr Overend's volumes, where they still remain, in the library of the Royal Institution in Albemarle Street; to which public body Dr Calcott soon after presented those curious manuscript volumes.

</table>

From this Table the primes 7, 11, 13, 17, 19, \&c. and their multiples, are not excluded, because intervals involving these do sometimes require to be calculated; the reason why two values are affixed to \( f \), and to some others of the primes differing by \( m \) or \( f \), is, in order that a regular interval may be made between every adjacent number, as \( \frac{1}{2}, \frac{1}{4}, \frac{1}{5}, \&c. \) A simple subtraction will give the value, whatever the terms of the ratio are found in the first column; and when this is not the case, the multipliers of each term must be sought, and the corresponding notations of each added together, and then the sums are to be subtracted; thus if the value of the minor tone, \( \frac{8}{5} \), were wanted, we have its ratio \( \frac{3}{2} \times \frac{2}{5} \), and

\[
\begin{align*}
970 & 19.84 \\
970 & 19.84 \text{ and } 1421 28 123
\end{align*}
\]

1940 38 168; 3033 40 176, the difference of which sums, is, 98 \( \Sigma + f + m \), the value sought.

Since, in the use of this notation, a carrying or borrowing to or from one column to another, never takes place, in whole numbers at least, as with columns of pounds, shillings, and pence, or yards, feet, and inches, \&c. but each column separately agrees in the result, it is plain, that either of the columns may be separately used, but with different degrees of exactness in some cases.

The middle column having 12 \( f \)'s to the octave, it is

After several hundred intervals, expressed in this new notation, had been collected from Mr Overend's MS. and many other sources, and arranged in a Table, according to their magnitudes, as before mentioned; it was observed, that all but a very few of them, formed a regular series, in which each of the three columns formed a separately increasing series of numbers; such, that if \( f, 1, 2, 3, 4, \&c. \) first appeared with \( \Sigma = 88, 30, 127, 174, 231, 278, 325, 358, 429, 486, 533, 590, 637, \&c. \) respectively; and \( m, 1, 2, 3, 4, \&c. \) first appeared associated with \( \Sigma, 8, 19, 34, 44, 55, 66, 76, 91, 102, 112, 123, 138, 149, 170, 185, 196, 217, 227, 249, 258, 263, 274, 289, 300, 310, 321, 336, 346, 357, 368, 378, 393, 404, 414, 425, 440, 450, 461, 475, 482, 497, 508, 518, 559, 544, 554, 565, 576, 586, 601, 612, 625, 633, 648, 658, 669, \&c. \) respectively. The intervals of the commencement of the \( f \)'s, being sometimes \( S \) and sometimes \( S \), commencing with \( 23 \Sigma + f + 2 m \); and the intervals of the beginnings of the \( m \)'s, either \( C, E \) or \( x \), commencing with \( 8 \Sigma + m \)'s, by help of which the musical student may readily construct for himself a Table of the above 71 regular intervals, and their logs, which we must reluctantly omit here for want of room.

All such intervals in Mr Farey's general Table, as do not conform to the above, with regard to the number of \( f \)'s and of \( m \)'s that contain with their \( \Sigma \)'s, have been denominated irregular intervals, such as \( d, e, r, x, f, f, x, f \), \( B, x, t \), none of which ought to have either \( f \) or \( m \), but consist of \( \Sigma \)'s only, to constitute them regular intervals; as \( p, D, \) and \( x \), ought to have no \( f \); and \( f \) to have an \( f \), and only two \( m \)'s, \&c. and these changes may be effected, and any intervals be brought into a regular form, by means of decimals in the schisma column, equivalent to the \( f \)'s or \( m \)'s, that may be added or taken away; reckoning each \( f \) as \( 1.4966965 \Sigma \), and each \( m \) as \( 0.00765241 \Sigma \); thus, for example, \( d \) in a regular Table, will be \( 3588795 \Sigma, \varphi = 10.149661 \Sigma + m, f = 31.8582014 \Sigma + f + 2 m, \&c. \)

If we consider, that whenever the prime number 2, is found involved or multiplied in the numerator, or least term of any musical ratio, it is equivalent to deducting an octave \( \frac{1}{2} \) from it; and if, in the denominator, it answers to the addition of \( \Sigma \); so \( 3 \) denotes the subtraction or addition of a major twelfth \( \frac{5}{2} \); both of which \( \frac{5}{2} \) \&c. expressed in the new notation, will enable us to find the expression for any interval whose ratio is given. We can, on the present occasion, only find room, for the first 25 numbers of Mr Farey's Table of this kind, viz.
In like manner, the third or m column of 53 parts in the octave, are the Artificial Comma of Mercator, as is particularly explained in our article Common Measures of intervals, and by help of which commas, the calculations of most intervals, except those near to or less than a comma, may be correctly performed. And, in like manner, the first column, separately considered, of a table of regular intervals, constitutes Mr. Farey's Artificial Comma, 612 to the octave; by means of which, the utmost facility, and every requisite degree of accuracy, is given to the calculations of all real or diatonic intervals larger than 3, (except sometimes confounding R and F, and also E and F,) mostly in whole numbers; and in the calculations of temperament, or where decisions or vulgar fractional parts of this artificial comma are used, even the smallest intervals, as well as the largest, are represented by them and decimals, with greater accuracy than it is practical to make experiments, or to apply musical calculations in practice.

FARMING. See Agriculture.

FARNHAM, a town of England, in the hundred of Farnham, and the county of Surrey, is situated partly on a hill not far from the north bank of the river Wys. The town consists of one principal street, with some smaller ones branching off to the north and south, and the houses are in general excellent. The principal public buildings and establishments at Farnham, are the castle, the church, and the market house, with a free school, and a good charity school. The castle is situated upon a hill, on the north side of the principal street. It was built by Henry, (brother of King Stephen,) Bishop of Winchester, and has ever since been the summer residence of the Bishop of Winchester. It was greatly injured in the civil war in 1642, but was rebuilt and repaired after the Restoration by Dr Morley, Bishop of Winchester. It is built of brick, covered with stucco, and is embattled, and of a general regular form. Some remains of the keep of the ancient castle are contiguous to the edifice. It is called Jay's Tower, which is ascended by 63 stone steps. It contains a kitchen garden on its top, consisting of 48 rods of land. The whole is surrounded with a strong stone wall, at the foot of which is a moat planted with oaks. The church, which was formerly a chapel of ease to Waverley Abbey, is at a little distance to the south of the High Street, and is a large building, apparently built about the end of the 15th or the beginning of the 16th century. It consists of a nave continued to form the chancel, with a north and south aisle. Its numerous windows are adorned with tracery; and the interior contains several handsome monuments, with a painting of the 12 apostles on an altar-piece. The tower, which is very substantial, has a small turret at each corner; and there is a bracket at the west end, which seems to have supported a niche for an image. Farnham was once celebrated for its cloth manufacture; and the hops cultivated in the vicinity of the town, have always been regarded as the best in England. A great trade in Welsh hose is carried on in the town. The following is the statistical abstract for the town and parish in 1811:

FARO, the name of a town of Portugal, in the province of Algarva. It is situated in a level and sandy plain, about a league from the sea, and on the bank of the river Da Quarteira. The town, which is quite open, is regularly built, and has tolerably broad streets, composed of small houses. The houses in that part of the town round the church of San Pedro, have still a Gothic appearance, as this was the only part of the town which escaped, when it was plundered and burnt by the English in 1586. There is a handsome square with some considerable buildings, situated on the side of the river; and one side of the town is defended by a small citadel. Faro is the see of a Bishop, suffragan of Evora, and has a governor, a brigadier, and a corregidor. It contains two parishes, and three monasteries. Small vessels can come up to the town, but large ones are obliged to unload in the road or lower down the river, which, after numerous windings, forms the narrow entrance of the harbour a league and a half to the south-east of the town. The harbour is defended by the fort of San Lourenço de Olhão, situated on the east side of the river. Another narrow arm of the river, or properly speaking of the sea, called a Barreira, forms an island, on which is the sandy cape of Santa Maria. In all the maps, this island is laid down at too great a distance from the land. The tract between the town and the sea is very marshy, and is covered with marine plants. It is flat and sandy on the opposite side; and at a distance rise the mountains of San Miguel, which are high and steep, but well cultivated towards their base.

The greater part of the trade of Algarva is carried on at Faro. Wine and fruits, but particularly figs, are exported in great quantities. The figs are thrown down by the country people in a heap, in a building for this purpose. The syrup which flows from them is used in making brandy. They are then spread in the sun in an open situation, and are afterwards pressed into small baskets made of the leaves of the fan palm, each containing 28 pounds. They are chiefly of the white kind, though the red, particularly the Figo do Encacho, and do Bispo, are most esteemed. Oranges and Spanish reeds are also exported from Faro to England. Number of houses 1200; population 5000. West Long. 7° 52', North Lat. 37° 2'. (J)

FAROE, the name given to a group of islands in the Northern Ocean, belonging to Denmark.

The early history of these islands, though they were colonized by the same people who rendered that of Iceland so extraordinary, presents nothing in the least degree interesting. They appear to have been resorted to long before Iceland was discovered; and the same cause, the subjugation of the petty states of Norway by Harold the fair-haired, led to the colonization of both in the 9th century. Those inhabitants of Norway who did not choose to submit to that victorious monarch, left their native country, and settled in Iceland, Faroe, Zetland, and Orkney. Lucas Debes, in his curious work Ferores Reservata, very justly remarks, that had the people of Faroe, who were of the same rank with those who
betook themselves to Iceland, been equally diligent in the cultivation of letters as their western neighbours, we might have had better and more interesting information handed down to us. It is not improbable that, as the Faroese employed themselves in piracy, they were objects of jealousy and attack; and being thus constantly engaged either in molesting their neighbours, or in defending themselves, education and literature would of course be neglected.

The islands were at first the property of various chiefs, whose petty warfare seems to have lasted a long time, until they were finally subdued by the kings of Norway. The Christian religion was introduced in the year 1000 by a native, Sigismund Bresteson, who was employed by king Olave Trygeson. The reformed religion appears to have been established about the middle of the 16th century.

In the last century, a very close connection between various parts of Britain and Faroe subsisted during the American war, and for some time after. They were found to be a most convenient depot for goods intended to be smuggled into this country; and regular establishments were made for carrying on a contraband trade. The frequent intercourse between the people of the two countries, rendered the English language familiar to the Faroese, of whom a considerable number is yet to be met with who speak it with fluency. The war with France, and the destruction of the Dutch and Danish East India trade, put a final stop to smuggling, and reduced the islands to a state of great poverty. In the year 1808, Captain Baugh was sent to Faroe very soon after the peace of war, and the fort at Thorshavn was destroyed, to prevent its being a protection to privateers. Some time afterwards, a German, assuming the title of Baron Honpesch, who had obtained a letter of marque, landed at Thorshavn, plundered the inhabitants of every thing, and broke into the church where the public chest was deposited. A small crucifix of silver, which stood on the altar, was seized with eagerness, but when it was found to be hollow, and of no great value, it was restored. The British government very properly and humanely refused to sanction these proceedings; and some disturbances having happened in the year 1809, between some British merchants and the Icelanders, an order in council was issued, commanding British subjects to consider the Icelanders, Faroese, and the people of the Danish settlements in Greenland, as strangers friend, and permitting a trade between these places and the ports of London, Leith, and Liverpool, on certain conditions. The money, and the value of all the goods of which Faroe and Iceland had been robbed, were restored.

In 1811, Lieutenant Banks of the Forward gun brig, was dispatched from Leith to make a report on the state of the Faroese islands, representations having been made to government, that the inhabitants were in great distress on account of the scarcity of provisions. Two ships, in consequence of Mr Banks's report, were permitted to carry corn and other articles from Denmark to Faroe, and to take Faroe goods in return, provided they touched at Leith to have their licences annually renewed. The peace concluded with Denmark in January 1814, and the recent arrangements with Norway and Sweden, will save the inhabitants from the risk of famine; but unless the Danish government becomes a little more liberal, and a little more enlightened, in regard to the management of their distant possessions, the people must continue in a state of miserable dependance, and without the means of improving the little soil capable of cultivation.

The Faroe islands lie between 6° 15' and 7° 43' Longitude West from Greenwich, and between 61° 20' and 62° 25' North Latitude. The group consists of twenty-two islands, of which seventeen are inhabited. Their appearance, whether when approached in fine or in bad weather, is inconceivably grand, especially from the south-east and west. While the sun approaches the western horizon, and the sea is smooth, with a gently undulating motion, nothing can exceed the sublimity of the scenery. The stupendous masses of light and shade, and the varying tints reflected from a thousand fantastic forms, hewn by the hand of nature from piles of rock, many of which soar to the height of 3000 feet, produce an effect beyond description.

The central island of the group, Stromoe, is likewise the most extensive, and contains the highest mountain. This island stretches (as all the others do) from nearly north-west to south-east, being in length 25 geographical miles, and on an average about 5 in breadth. It is deeply indented by bays and creeks, some of which form commodious and safe harbours, particularly that of Westmanna, which is fit for the reception of every description of ships. The south-west and west coasts present finely varied and magnificent rock scenery, more especially the west, where, for a distance of about 12 miles, the eye meets continued changes in the forms of the precipices. To enjoy such scenery in perfection, one must coast along in a boat at a short distance from the rocks. The curious traveller may, in this manner, obtain the greatest enjoyment. Sometimes he may enter a cavern, and, after exploring it till he almost loses the light, may find himself yet at a distance from the place, where the swell meeting the bottom of the abyss recoils with a tremendous roar. Often, while he is admiring the singular forms of the precipices, the boat passes through a perforation, and he finds them detached from the mountain, and standing like huge walls, towers, or castles, surrounded by the sea. On these the sea birds have their nests, and there the hardyowler fearlessly robs them. On this remarkable coast, the rocks soar from 1500 to 2000 feet. Each island has its beauties; and there is scarcely a promontory or detached rock, that does not present something combining singularity with magnificence. Of these, the rock called the Witch's Finger, and the little island called Tindholm, the one on the east, and the other on the west side of Vaagoe, are perhaps the most remarkable. The former is detached from the adjoining precipice almost to the bottom. From some points of view, it has the appearance of a grand square tower, surmounted by a lofty spire; and when the light falls in a particular direction, the resemblance of a door and windows are quite distinct. This was observed by the writer of this article at a distance of five miles. When viewed in that position in which it appears detached from the rock, it is not unlike a huge finger pointing upwards. Landt states the height of this peak to be 1200 feet, and we believe that this does not much exceed the truth. The elevation of Tindholm is probably about 500 feet, and its singular appearance is much more striking. On one side, though very steep, it is covered with verdure almost to the summit, which consists of a number of long and slender peaks ranged along the ridge, which terminates on the opposite side a perpendicular face of rock. In crossing the island of Vaagoe towards this rock, its summit is seen in a form
bearing a very close similitude to the towers and pinnacles of Westminster Abbey. In some places, there are ranges of columnar rocks; but, in general, they are not in such situations as to render them of much importance in the scenery. The promontory of Niewen in Streymoe, presents a very beautiful range of columns. There are some in Osteroee, which are lofty, but from their situation not very striking. Several very curious columnar rocks are to be seen in Suderoee and Myggeanes.

The highest mountain is that called Skelling field, or Skelting Field, which rises very abruptly, terminating in a small platform. It exceeds 6000 feet in height; but it has not yet been very accurately measured. The frequency of fog, which often suddenly envelops the adventurous traveller, even in fine weather, renders the ascent of the Faroe mountains a very hazardous undertaking. The height of Slatturttinde, in Osteroee, is 2825 feet; and there are several mountains in the same island, which appear equally high.

There is nothing in Faroe which can be called a valley; the mountains for the most part meeting at the bottom, and having only a small rivulet as a boundary. There are a few lakes, the largest of which is in the island of Vagoe, being about three miles long, and one in breadth. Beyond the upper end of the lakes, there is generally a small extent of flat ground.

The inhabitants have chosen for their villages such spots as are dry, or may be rendered so easily, and which have the advantage of a commodious landing place for boats; though this last, in a few instances, gives place to the former.

Many of the occupiers of land hold it in property; and others of the crown of Denmark, paying a tax for it of from 20 to 40 skilling for each mark. A mark is an extent of land which rarely supports more than two cows during the year, though some maintain four. It is generally reckoned to be about 8000 square Danish ells; but the mark varies in different places, and is valued at about 600 dollars.

The whole surface of the country is very wet; and, in general, the soil is thin, and for the most part consists of peat. On such a soil, under a climate, not indeed rigorous, but exceedingly moist, and consequently ungenial, from the rays of the sun being so much excluded from the surface, agriculture cannot be supposed to be in a flourishing condition. The inhabitants being regularly supplied from Denmark with barley and rye, and sometimes with peas, the cultivation of grain is carried to a very small extent, while hay for the cattle during winter is an object of the first importance. By repeated working, the land is thrown up into ridges, a section of which exhibits this form, — the length of the ridge lying along the seclivity. This is undoubtedly the best form that could be devised for carrying off the surface-water with the least damage to the soil. When barley or turnip seeds are to be sown, or potatoes planted, a large dose of manure, made up of dung and ashes, is spread upon the first ridge. The turf is then cut from the next, and laid with the grassy side downwards on the dung. This is chopped with a spade, and a little more soil is laid on, and the seed scattered over it, when it is again stirred with the spade.

No grass seeds are sown; and, before a miserable crop of hay can be reaped, the land must lie waste for three years, when a coarse herbage, the greatest part of which consists of sorrel, is collected by nature. It is a fact for which no good reason can be discovered, that the vegetative power of the grain imported from Denmark is previously destroyed by kiln-drying; and thus the poor Faroese are compelled to sow their own shrivelled and unripe corn. The turnips which grow in Faroe are a yellow sort, but small and hard; and the potatoes are diminutive and watery. Such, however, is the industry of the people in some places, that soil is often seen laid on the flat surfaces of large stones, in which potatoes of very good quality are produced.

The cattle are very small; and no pains being taken to select the best for breeding, from a few are to be met with that are well shaped. They yield but a small quantity of milk; but it is sweet and rich. The sheep vary a little in appearance, and in the quality of their wool. This is owing to a supply having been brought to the country, after a season of unexampled fatality among the native sheep, partly from Iceland, and partly from Zealand. From the wool, excellent strong stockings are manufactured, and likewise close jackets, which are worked, like stockings, on wires, and ornamented with figures done with variously coloured worsted, dyed in the country. To give a yellow colour, the Arthricum ossifragum, Polygonum hidropepp, Polygonum persicaria, and the Lycopodium complanatum, are used; for black, the Geranium sylvaticum; for red, the Lichen calceatus and the Lichen tartareus; for brown, Lichen saxatilis and Omphaloides; and for orange, the Lichen parietinum.

The wool is torn from the sheep when the fleece begins to loosen; but frequently that event is not waited for, and the skin of the animals is often cruelly lacerated. The horses are small, and in general not well shaped. The best are to be seen in the island of Suderoee. They are very seldom used, except for carrying home fuel from the moors; there being no roads and no wheel carriages.

It might be supposed, that the sea around these islands was a never-failing source of subsistence and profit to the people who inhabit them. Formerly a considerable fishery for cod was carried on; but now it appears, that the only bank in the vicinity (which is about two miles north of Kalsoe) is almost totally destitute of fish. The accounts of this failure, which the writer of this article received, may, however, be somewhat exaggerated. It is indeed true, that fish are not abundant on the coasts; but there appears no indication to prosecute the fishery with vigour. It seems to be the policy of the Danish government, to keep the natives of their distant possessions in a state of poverty and perpetual dependance, and to encourage merchants from Denmark to provide them with grain and other necessaries, which are exchanged for the woollen jackets and stockings, the manufacture of which is the chief employment both of the men and the women. Of these goods a very large profit is made on the continent. The price of grain, however, is never raised to the Faroese, whatever it may cost in Denmark; and when it is brought to Faroe, it is divided with scrupulous accuracy, and distributed according to the circumstances of the different classes of inhabitants. Barley is the principal article; pease, rye meal, and oats being less commonly used. In the year 1812, 5650 barrels of grain and meal were imported; and this quantity was considered as a sufficient supply. There being 5120 people in all the islands together, each person, supposing the provision to be equally divided, would...
The only other source of subsistence which remains bird-catch to be mentioned, is the great number of sea birds which nestle in the rocks. Of these, the puffin (Alca arctica) is the most numerous, and the most sought after. But various other kinds are taken. The eider duck, which in some other countries is so carefully protected for its down, is here often shot for food. The bird-catchers are exceedingly adventurous; and as this is the first opportunity we have had of describing this hazardous occupation of the inhabitants of many northern countries, an account of it may entertain our readers.

The fowlers are provided with long poles, to the ends of which are fastened small poke nets. With this instrument they generally display great dexterity in casting it over the birds, which invariably make towards the water when they are disturbed. It is this anxiety of the birds to seek the element in which their security is to be found, which gives certainty to the exertions of the fowler. The birds push their heads through the meshes of the net, which being dexterously inverted, keeps them suspended by the neck.

When a fowling expedition is undertaken, two men fasten themselves to a rope, so that there may be eight or ten fathoms of it between them. One assists the other to ascend the rock by means of a pole, at the end of which is a hook, which is fastened to the band of the climber's breeches, or to a rope tied round his waist, and thus he is pushed up: But the most common method is for the climber to seat himself on a board fastened to the end of the pole. They often ascend frightful cliffs without any assistance. When the first has got to a place where he has some footing, he helps the other up by means of the rope to which they are both fastened. When they have gained the elevation where the birds are pretty numerous, they assist each other from cliff to cliff. It sometimes happens that one of them falls and pulls the other after him, when both are precipitated into the sea, or dashed to pieces on the projecting rocks. When the rocks are so high and smooth as to render it impossible for the fowlers to ascend, they are let down by means of a strong rope from above. To prevent the rope being cut, a piece of wood is placed at the verge of the precipice. By means of a small line, the fowler makes signals to those above, and they let him down or pull him up accordingly. When he reaches a shelf of the rock where the birds have their nests, he entices himself, and proceeds to take them. Sometimes he places himself on a projecting rock, and, using his net with great adroitness, he catches the birds as they fly past him; and this they call heining. This mode of catching birds is even practised while the fowlers are suspended. When a projection of the rock is between the fowler and the place where the birds are, he swings himself from the rock so far that he turns round the projection. In this, great address and courage are requi-
Faroe.

site, as well as in swinging under a projection into a
cavern. When he cannot, with the help of his pole,
swung far enough, he lets down a line to people sta-
tioned in a boat below, who swing him, by means of it,
as far as is necessary to enable him to gain a safe place
to stand upon. Besides being exposed to the risk of
the rope breaking, the fowler is frequently in danger
of being crushed by pieces of the rock falling down
upon him. — Such are the hazardous means to which
these poor people resort for procuring food.

Seals were formerly taken in the caverns which
abound on the coasts, in great numbers; but they are
either not so numerous now, or there is less induc-

tement for their capture.

Thorshavn, the principal place in the country, is si-
tuated on the east side of Streymoe; the houses being
built on a narrow tongue of land jutting out into the
sea. Two small creeks are thus formed, in either of
which vessels may be safely moored, large iron rings
being fixed in the rocks, on both sides, for that purpose.
The houses are constructed of wood, and crowded to-
gether without any regularity. The roofs are covered
first with birch bark, brought from Norway, over which
turf is laid. The green colour of the tops of the
houses assimilating with that of the soil around the
town, renders the place almost invisible from the
sea, at a very short distance. The house of the com-
mandant is the best furnished, but that of the land-

gaged, (who is here high sheriff as well as treasurer,) is
the most spacious. Though the exterior of the build-
ings does not promise much, yet the rooms are generally
neat and clean. The church is a large wooden edifice,
covered with slate, and painted white. It has a small
steeple, and altogether its appearance is very respecta-
table. There are many large storehouses in different
parts of the town, several of which are now locked up,
on account of the almost total annihilation of trade.
The prison is a small wretched building of stone, in
which those convicted of crimes, such as sheep-stealing,
are confined for several years. They are brought out
occasionally, however, to work when any thing partic-
ular is required to be done. At the mouth of the
harbour are the remains of a small but strong fort, the
guns of which were destroyed in the year 1808.

The houses of the farmers and of the clergy are in
general good. In all of them the traveller will find his-
self hospitably received, and accommodated with an
apartment as neat and clean as he could desire, though
not elegant. The hospitality of the poor Faroese is
really remarkable; the readiness with which they
produce their little stores to share them with a stranger;
their alacrity in complying with his wishes, and their
anxiety to anticipate them, are, to a mind not altogether
devoid of feeling, truly affecting. In their deportment
they are exceedingly polite and respectable; and the
strict honesty which was experienced by the writer in
numerous instances, during his intercourse with the na-
tives, raised their moral character very high in his es-

timation. To religious duties they pay the most regu-
lar attention. Almost every village has a church; and
when the priest is engaged elsewhere, or detained by
the weather, the clerk reads the service. On the Sun-
day evenings, and on holidays, the people give them-
selves up to merriment. In fine weather, groups of
them are seen in the fields, formed into circles, moving
round in slow cadence, (which they call dancing,) to a
song in which sometimes 15 or 20 voices join. The sub-
ject of the song is usually some achievement of their
forefathers, or the history of faithful lovers; and the

airs are wild and not without harmony; they are, on
such occasions, dressed in their gayest clothes, and they
often continue for several hours, singing and dancing
with scarcely any interruption.

Debes relates several superstitions which were pre-
valent in his time, but which are now exploded. Still,
however, some remnants of credulity may be traced,
and some persons are to be found, who believe that they
have seen the phantoms of people at a distance, at the
moment they expired, and thus had notice of their death.
In this respect the Faroese are not more superstitious
than the common people in many districts of our own
country.

Barley bread is that which is commonly used in Fa-
roe, rye being imported in very small quantities; this,
with milk or fat, constitute breakfast. In the autumn,
when the lambs are slaughtered for drying, the blood
is boiled with the milk. Dinner consists of fish and wa-
ter gruel, improved by being boiled with bones or fat.
Soup is sometimes made with fresh or dried meat, and
turnip leaves. Dried lamb is eaten raw with tallow, and
dried whale flesh is esteemed a delicacy. On holidays
a large pot is placed on the fire, and a quantity of sea-
birds boiled for supper. The quantity of fat which
these people swallow, and the state in which the rest of
their animal food is taken into the stomach, might be
deemed unwholesome; yet diseases are not frequent,
the appearance of the inhabitants being every where
robust and healthy; the children, however, are gene-

Dress.

The dress of the men of Faroe consists entirely of
woollen stuffs, manufactured in the country. Their
jackets, which are worn in their ordinary occupations,
are knitted, and ornamented with figures in coloured
worsted. In full dress, they wear a long frock of a
dark brown or black colour, and breeches of the same.
Their shoes are made of sheep skin, slightly tanned with
the root of tormentilla. They are formed by cutting a
piece of skin of a proper length and breadth, and puc-
kering, very neatly, the parts for the toes and heel: the
fastening is a white woollen thong, knitted for the pur-
pose, and tied round the legs. The dress cap is form-
ed like a bishop's mitre; on ordinary occasions they
wear woollen caps, and sometimes caps of skin, with
the hairy part outermost. The men never cut their
hair; and to appearance seldom comb or wash it.

The women wear their hair combed backwards from
the forehead, and have white linen caps with a broad
stiff border of coarse lace, rising perpendicularly. The
cap is fastened by a coloured silk or cotton kerschief
tied under the chin, with a piece of ribbon floating behind. The rest of the dress much resembles that of the peasantry in most parts of Scotland, the materials being coarser. They wear aprons, and cotton kerchiefs over the shoulders and bosom. The greater the number, and the more gaudy the colours, the more superb is the dress considered. A bride on her wedding-day is very gaudily ornamented: a red or blue jacket, with long skirts pucker up into folds, having long sleeves, with velvet cuffs and lace ruffles, constitutes the principal part of the dress. The kerchief worn round the neck is, on this occasion, white, with a border of lace. On the bosom is fastened a large pin or brooch, having a broad silver plate in the shape of a lozenge, to which are appended a great number of small flat pieces of silver, which, on the wearer moving, make a jingling noise. The head dress is much ornamented with ribbons, and gold and silver ornaments.

The language of the Faroese, from the circumstance of its never having been written since the settlement of the people in the islands, has become very different from what it was originally. It may still be traced, however, to its parent the Scandinavian, or, as it may now be called, the Icelandic. Almost all the natives can speak the Danish language, in which divine service is performed.

There are now no schools in Faroe; but parents do not neglect to teach their children to read, and sometimes to write. The people are fond of reading; and several of them, with whom the writer of this article conversed, shewed great eagerness for information of every kind. One of them to whom he explained the use of the barometer, which seemed to excite great curiosity, was exceedingly delighted, and appeared to comprehend perfectly its use in measuring the heights of mountains. He remarked that he was now an old man, but that he could never be too old to learn. The name of this person is Hans Alaik. He conducted Sir John Stanley through some of the islands upwards of 20 years ago, and was the interpreter and guide of the writer of this article.

The census mentioned by Lundt was taken in 1782, and the number then was 4409, which gives an increase in 1812 of 800.

Where mechanical labour is so little required, separate trades are not to be looked for. Every one can provide himself with clothing, and can act as a carpenter. Clothing is carried chiefly in Nalsoe. Both men and women employ themselves in spinning wool and in knitting. The Faroese loom is a very rude machine; but the cloth which it forms is of a very good texture. The loom consists of two upright posts set up against the wall, and having two projections to support the beam, to which the upper ends of the warp are fixed, the lower being attached to stones, which keep the threads stretched tight. The warp is passed through the warp by the hand, and forced up against the warp by means of a small piece of wood; after which it is pushed firm by means of a smooth whale rib. This operation is exceedingly slow, as at each movement the threads must be unwound from the stones. In Thorshavn there are a few looms of improved construction.

The trade is carried on by the Danish government through the intervention of a respectable house in Copenhagen. The exports are stockings and jackets, train oil, feathers, and skins. Tallow, fish, and butter, are now so scanty as scarcely to supply the wants of the natives. The imports are, grain, fishing materials, tobacco, a little sugar and coffee, timber, tar, nails, lead, gunpowder and some other articles, all in very small quantities. Stockings and jackets are at present the chief articles of export.

The revenue is collected out of the produce of the country. For every sheep of the permanent or estimated stock of each farm, a lamb's skin is paid; and, for every sixty sheep killed, 30 lbs. of tallow, and thirty skins. The proportion of wool paid as tax, is sold at a fixed price to the people of Thorshavn. Formerly, the whole revenue usually amounted to between 3000 and 4000 rixdollars.

The religious establishment of Faroe is now under the superintendence of a provost. There are seven parishes, and 39 places of worship, so that the duty of the clergy is exceedingly laborious. The stipends are inconsiderable, and are chiefly paid in kind. To the glebes a permanent stock of sheep, and sometimes a few cows, is attached. Glebes are also provided for the widows of the clergy.

The civil establishment is under the direction of a military officer, commanding 30 men, who maintain the form of mounting guard, and keeping a look out for ships. Under the commandant are, the landfoged or treasurer, and the syssemen, or governors of districts.

The natural history of these islands, if we except the department of mineralogy, presents nothing that is uncommon to other countries in the same latitude. On the contrary, they are very deficient both in their botan...
Farquhar, George, an eminent English comic writer, was born in the year 1678. His father was a respectable clergyman in the north of Ireland, who, having a numerous family, could not bestow any fortune upon him, but resolved to give him such an education, as might enable him to prosecute some genteel profession.

Farquhar discovered an early taste for literary pursuits, and is said to have written verses when only ten years of age. In 1694, he repaired to Trinity College, Dublin, where he made such progress in his studies, as procured for him considerable reputation. It would appear, however, that his prudence was not equal to his literary attainments; for he was expelled the college, in consequence of having ventured profane wit upon a sacred theme, given to him, as an exercise, by his tutor.

At an early period of life, he turned his attention to the stage, intending to follow the profession of an actor; in which career he was not very eminently successful. He possessed an engaging person, and genteel manners, but his voice was weak, and he had a natural timidity in public, which he could never overcome, and which was extremely prejudicial to his appearance on the stage. He resolved, however, to continue the exercise of this profession, until some better prospect should open; but this resolution he is said to have abandoned, in consequence of the following accident. While performing the part of Guzman, in the Indian Emperor, who is supposed to kill Vasquez, one of the Spanish generals, having forgotten to exchange his sword for a foil, in the engagement he wounded the person who represented Vasquez, though not dangerously; and this unfortunate incident had the effect of preventing him from again appearing on the stage as an actor.

Some time after this, the Earl of Orrery gave him a lieutenancy in his regiment, then in Ireland; and Farquhar is said to have conducted himself well as a soldier. He was honoured and beloved by his comrades, and proved himself to be a man of courage and conduct.

In the year 1704, he married a lady, who was so violently in love with him, that, despairing to win him by her own personal attractions, she contrived a deep scheme of imposture, by which she allured him into bedlock, under the impression that he had married a woman of immense fortune. But it redounds highly to the honour of Farquhar, that, after he had discovered the deceit which had been practised upon him, he entirely forgave the lady her fault, in consideration of her love and accomplishments; and always treated her with kindness, although this unfortunate marriage is supposed to have conducted, with other circumstances, to shorten his days: for his fortune was too slender to support a family; and the maintenance of his wife and children reduced him to the utmost poverty, while his anxiety for their welfare preyed upon his spirits, and injured his health. He died at the age of 29, four years after his unhappy marriage, and is said to have met his fate with fortitude and cheerfulness. He left two daughters, whom, in the following letter, written a few days before his decease, he recommended to the protection of Wilkes, the celebrated actor, with whom he had contracted a sincere and intimate friendship when upon the stage, and for whom he wrote the famous character of Sir Harry Wildair, in the Constant Couple.

"DEAR BOB,

"I have not any thing to leave you to perpetuate my memory, except two helpless girls; look upon them sometimes, and think of him that was, to the last moment of his life, thine,

GEORGE FARQUHAR."

Wilkes humanely complied with the dying request of his friend, and assisted in providing for the children. Their mother died in great indigence.

Farquhar was eminently successful as a dramatic writer. During the vicissitudes of a chequered life, as a man of fashion, an actor, an officer in the army, an author; a lover; and a husband, his experience had supplied him with incidents, and his observation and reflection with a knowledge of human nature. His subjects are generally well chosen, his characters well sustained, his style pure and lively, his dialogue easy and spirited. But his humour is not remarkable for delicacy; and his plays have an obvious tendency to encourage licentiousness of manners, and a disregard of moral principle.

He wrote seven comedies, of which the most esteemed are, The Constant Couple, The Inconstant, The Recruiting Officer, and The Beaux Stratagem, which are still occasionally acted, and preserve their popularity on the stage. (2)

FAIRS, or FARSIAN, is a province of the kingdom of Persia, bounded on the north by Irak, on the east by Kerman and Laristan, on the west by Kuzistan, and on the south by the Sea of Oman. It is divided into two climates, the warm and the cold, which are designated by the names of Germaseer and Sirdul. The warm climate extends from the sea to the latitude of Kazeroon, and then runs parallel with the Gulf from the banks of the Tab to the confines of Laristan. When the periodical rains are abundant, the sandy plain at the foot of the mountain produces a considerable quantity of dry grain; but when the rains are less abundant, a famine generally happens. This sandy plain, which is called Dushistian, is divided into the districts of Leerawee and Hiadoust, which are separated from...
each other by the projecting mountain called Kopi Bung.

These districts, which contain only a few wretched mud villages, are very badly cultivated. The Cold Region stretches from the parallel of Kazeroon to that of Yezechkast, on the borders of Irak. It comprehends most of the mountainous part of Fars. The mountain vallies are generally 8 or 10 miles broad, and from 15 to 100 long. They afford abundance of pastureage, and are commonly fertile, though ill cultivated. The plains of Sheeraz, Kazeroon, and Merdesht, however, are in pretty good cultivation; but, towards the north and west, they are almost unpeopled. Mr Kinneir travelled, in 1809, above 60 miles between Behaban and Sheeraz, through the most charming wooded vallies, without seeing the face of a human being. An ancient tribe which formerly inhabited them, had been almost extinguished by the orders of the prince; and the few which had escaped to the summits of the lofty mountains, subsisted upon a wretched kind of bread made from acorns, and upon the pillage of travellers.

The eastern part of the province towards Darabgherd and Fasa is more open. The soil is more sandy, and the plains more extensive.

The range of mountains seen from the coast is not a separate range, but a branch of Mount Zagros, which stretches in a continued succession of ridges from the borders of the Persian Gulf to the Caspian Sea and Mount Caucasus.

The hills in this province towards Bushire, are about 24 miles from the sea. The plain becomes contracted towards Bunder Deelum; and to the west of the village of Guana, a low ridge suddenly projects to the south, and terminates at the sea shore in the projecting point of Kohi Bung, which separates the districts of Learaee and Hidount. This point is not high, but is about 7 or 8 miles broad, and beyond it lies the plain of Learaee. The mountains are here again 20 miles distant from the sea, and for 18 or 19 miles they preserve this distance, but afterwards approach the south, and assume a circular form near Bunder Deelum. On turning the southern point of this low and advanced branch, which is called Zeitoon, from a small town near Behaban, they again retire to the north, and at the port of the Mashoor they are 30 miles from the sea. Their most southern extremity at Shuster, crosses the 32d degree of North Latitude, in the 49th degree of East Longitude.

The principal rivers, are the Tab, the Arosis of the ancients; the Jerahi, the ancient Pasigiris; the Bund Emeer, and several others, whose modern names are not mentioned. The Tab, which is the largest, is formed by the union of two streams near Zeitoon, one of which rises at the foot of the high hill of Kamarak, and the other near that of Ardicoone, about 45 miles north-west of Sheeraz. Mr Kinneir considers this latter branch as the river mentioned by Arrian in the march of Alexander. The Tab separates Fars from Kuzistan, and passes through the town of Endian, where it is 80 yards wide (in Feb.) and navigable for boats of 20 tons burthen. There is a ford about 9 miles above the town; and the Tab discharges itself into the sea about 18 miles below Endian. The water of this river is perfectly sweet when it passes Zeitoon; but in running over the hills towards Endian, it becomes so brackish as hardly to be fit for use. This is also the case with all the other rivers in Fars, which empty themselves into the Persian Gulf.

The river Jerahi, which is next in size to the Tab, rises in the mountains immediately behind Behaban, and after flowing within a few miles of that city, it passes through the vale of Ram Hormuz to old Dorak, in the territory of the Chab Sheikh, where the Arabsians have erected a dam, for the purpose of irrigating the fields, leaving two chief branches, one of which passes on the outside and the other through Dorak. The marshes in the neighbourhood of this town are occasioned by the lesser branches. One of the principal branches enters the Kooron above Sable, and the other empties itself into the sea at Goban. In passing through the vale of Ram Hormuz the Jerahi receives a rapid river which flows from the mountains about six miles east of the town of Ram Hormuz. This tributary stream contains a great body of water, and is not fordable after the melting of the snows. It is the river alluded to in the marches of Timour. The river Bund Emeer, called by some of the ancient Cyrus, and by the Greek historians Araxes, flows through the delightful valley of Merdesht, adorned with the ruins of Persepolis, and in the rich districts of Kurjan it is subdivided into numerous streams for irrigating the fields. The remaining part of the river is joined by Shamer, a small stream which rises in a hot fountain, three miles from Gzian, a town about 90 miles from Sheeraz, and afterwards passes the villages of Kunm and Suvund. The united streams then discharges themselves into the lake Baktegan.

In travelling from Bushire to Endian, Mr Kinneir passed other four rivers. The first of these rises among the mountains behind the old city of Shapur, and after running through this city, and watering the villages of Kesh and Dalke, it enters the Gulf a little to the south of Rehilla. Mr Kinneir supposes it to be the ancient Heraenias. At Rehilla it is 60 yards broad and six feet deep. The second river, which is thought to be the Gratars of Arriyan, is only seven miles to the north-west of this. It discharges itself into the bay, which way between Rehilla and Bunder Reig; but it is neither so wide nor so deep as the former. The third, which is the Rogani of Arriyan, runs with a south-west course from the mountains, and throws itself into the sea three miles north-east of Gunuva. It is almost equal in breadth to that of Rehilla. At high water it is impassable, but it is only three feet deep during the ebb. The last and the smallest river, which is probably the Brizana of Arriyan, flows between Hissar and Bunder Deelum. After a wandering course from the hills of Zeitoon, it discharges itself into the Gulf, eight miles south-east of Bunder Deelum.

The salt lake of Baktegan is about 75 English miles in circumference, and is situated about 10 miles south-east of Sheeraz. In summer, when it is nearly dry, the people on its banks collect the salt, which encrusts the bottom. This salt is generally used throughout the province, and is reckoned a very fine sort.

The principal towns in Fars are Sheeraz the capital, Towns. Kazeroon about 70 miles nearly west of Sheeraz, Shapur, Bushire, Bunder Reig, a sea-port with about 300 or 400 inhabitants, Bunder Deelum another sea-port having about 700 inhabitants, Zeitoon with a population of about 2000, Behaban, the capital of the mountainous district of Khogiloca, having walls about three miles in circumference, and nearly 10,000 inhabitants, Faryawoom, Selbistan with 4000 inhabitants, Niris, Feza, Darasbord with 15,000 or 20,000 inhabitants, and Ursinjan. For more complete information respecting these towns, see Kinneir's Geographical Memoir of the Persian Empire, page 94-95, to which we are in-
FASCINATION is the name given to an influence which certain animals are supposed to possess over other animals, which serve them for food. This faculty has been ascribed to toads, hawks, cats, owls, tigers, and various other animals, but particularly to the rattlesnake and other American serpents. It is supposed by some naturalists, as Kalm, that the small birds, squirrels, &c. which have been seen to fall from the branches of trees into the mouth of the rattlesnake, must have been previously bitten by the snake; and being thus debilitated, were unable either to escape or to remain upon the tree. Others, as La Cepede, suppose that the rattlesnake produces the effect by a stupefying vapour emitted from its body; while others, as Linnaeus and Blumenbach, ascribe the effect solely to the terror inspired by the rattle which is supposed to reside in the tail of this animal. Dr. Benjamin Smith Barton of Philadelphia, has drawn up two very interesting memoirs, the object of which is to prove that there is no solid foundation for the opinion that serpents are endued with the faculty of fascinating and charming other animals, and we think that he has succeeded, at least, in rendering this opinion very doubtful, if not in completely overturning it. Such of our readers as wish to prosecute the subject, are referred to the following works, where they will find ample information on the subject.

FASTING, the partial or total abstinence of mankind and animals from the ordinary and requisite supply of aliment, by which it is to be understood that quantity which is adapted to preserve them in a healthy and vigorous condition. We have already given a few examples under Austerity, of the faculty of living creatures to resist destruction, while exposed to absolute privation of subsistence; and we shall now take a brief view of the consequences of diminishing the usual subsistence of mankind. It is a prevalent opinion, that the sudden reduction of food will immediately prove destructive, especially if to a great extent; and that death will ensue from total privation, even for the shortest term beyond the interval of gratifying our accustomed necessities. But nothing can be more erroneous; for the reverse is satisfactorily established by well-authenticated instances.

Those animated tribes whose subsistence is derived from the uncertain capture of prey, and in this number man must be ranked in his original state, are in general capable of resisting the impressions of hunger for a considerable period. Sleep follows the labours of the chase, and digestion is not conducted with rapidity. Removed from that original state, however, custom usurps the place of nature; and, on looking to the enormous quantities of food consumed by those around us, we should be apt to conclude, that not less than several pounds daily are required for the preservation of health and vigour. Probably there is no race of mankind on the known globe, that practises such an indulgence of appetite as a large proportion of the population of these kingdoms, nor by whom any abridgment would be more sensibly felt; and it accordingly appears, that in warfare, on occurrence of such occasions, the same energies decline, which, opposed to the combats of other nations, have previously proved successful.

In some uncivilized countries, the supplies of food are scanty and precarious. After enjoying one meal, a long interval may elapse before obtaining another; yet the inhabitants do not diminish. On the Continent of Europe, the meals of the people for the most part are few and sparing; and the inhabitants of the East are almost universally abstemious: a cake of meal, and cacao's are the chief sustentative articles. Millions of Indians subsist, for the most part, on maize alone, with water for their only beverage. Nay, if we look into the state of the poorer classes in some parts of the British dominions, we shall find many families subsisting on nothing but potatoes, with scarcely the addition of milk.

But there are countries absolutely sterile by nature, though inhabited by men; others have not yet been reclaimed by agricultural operations, or, if they have, the uncertainty of the climate frequently disappoints the labours of the husbandman; and in this way does the first gradation of fasting arise. The vast continent of New Holland, except for few and distant patches, exhibits an universal aspect of sterility. The vegetable kingdom scarce offers any substance for consumption; there is hardly a species of fruit exceeding the size of a cherry; nutritious roots are rarely discovered; and, in so wide and open a territory, the animal tribes can seldom be obtained for sustenance. The incessant pursuit of those of larger size, as the cassowary and kangaroo, has rendered them scarce, while it diminishes their numbers. Fishing is a precarious resource, both from the imperfect implements of the savages, from the storms which constantly assail their coasts, and more especially from the migration of the fishes themselves. The lank visages and emaciated bodies of the natives of the An- daman islands, indicate how sparingly the cravings of nature are satisfied. They live in an abject and degraded state; and, like brutes, their whole time is occupied in obtaining a supply of food. Hitherto no attempts have been made by them to cultivate the lands upon which they dwell; and their whole subsistence is derived from what they can collect or kill. Though their country be less inhospitable than that of the New Hol- llanders, and their vegetable diet consist of the pro-
duce of their woods, little is found there which is palatable to Europeans; and, as they have no vessel which can withstand the action of fire, they are unable to reap much advantage from such esculent herbs as may be contained in them. Their principal subsistence depends on collecting fish from the reefs at the recess of the tide; and the greatest part of the drudgery of doing so, falls on the women, while the men occupy themselves with hunting in the forests.

Independent of natural sterility, there are countries which, after it has been conquered by the industry of mankind, are occasionally visited by famine. In Norway and Lapland, during times of scarcity from unexpected failure of the crops, the inhabitants grind down the bark of trees, which, with the addition of a little meal for a relish, is baked into cakes; and are presented not to be impalatable, while they are sufficient for the preservation of life. Famine more terrible is experienced in populous countries, such as occurred a few years ago in Bengal, when many thousands perished; and such as are of frequent recurrence in the great empire of China, where they seem to threaten the very extirpation of the people.

This calamity, no doubt, affords too many examples of the sufferings of abstinence; but those are principally recorded which have arisen from shipwreck, and similar accidents, from peculiar mental affections, or from the body being in a morbid state, or from the two latter combined. Neither is it to be omitted, that voluntary fasting, in observance of religious ceremonies, has frequently been carried to a great extent. Thus the Mahometans, during one of their fasts, are scarcely sensible of inconvenience in fasting 40 days, from sunrise to sunset. In sacred writ it is recorded, that Esther, the queen of Ahasuerus, when apprehensive of a public calamity, said, "Go and gather together all the Jews that are in Shushan, and fast ye for me: and neither eat nor drink 3 days, night or day. I also, and my maids, will fast likewise; and so will I go in unto the king, which is not according to the law: and if I perish, I perish. So Mordecai went his way, and did according as Esther had commanded him." To descend to modern times, however, Dr Percival of Manchester relates, that he was informed by a young Genevese physician who had studied at Montpelier, that he then fasted three days and four nights, without any other refreshment than a pint of water daily. But during this probation, though his person did not suffer, he was affected with mental imbecility; a general consequence of thus exhausting the powers of nature. In a melancholy and well-authenticated instance of shipwreck, which occurred in the year 1795, 72 individuals were compelled to take shelter in the shrouds of the vessel, while the hull was covered by the sea, where all survived during five days, without a morsel of food; but it appears that they were enabled to catch a few drops of rain as it fell, and some of them were drenched with the spray. A term of abstinence still longer, is equally authenticated in the case of Thomas Travers, who, on Saturday the 4th of December 1784, entered a coal pit 270 feet deep, the sides of which immediately fell in. The quantity of earth was so great, that six days were occupied in removing it; and no one could at first venture to penetrate the pit, on account of the foul air which was evidently present. Some miners, bolder than their companions, made a new attempt on Friday, and, guided by the traces of his work, found the unfortunate man lying on his face in a cavity. He could raise his head, but his hands and feet were cold, and pulsation almost extinct. Immediate relief was afforded; but next morning he became indifferent about food, and, having announced his own dissolution, expired in a few minutes, on Sunday afternoon, after fasting seven days. This example illustrates the opinion of Hippocrates, though it is not corroborated by others, namely, that fasting less than seven days is not invariably fatal, but after that period, notwithstanding individuals may survive and take food, their previous abstinence will occasion death. It is to be observed, that here was an instance of absolute privation. In the year 1768, Captain Kennedy was shipwrecked, with 12 companions, in the West Indies. They preserved a small quantity of provisions, which were totally consumed in seven days, during extraordinary distresses. During eight succeeding days, though in absolute want, both of meat and drink, and exposed in an open boat, the whole survived; but, after obtaining relief, some of the people perished. In this case they were evidently supported by being frequently drenched with sea-water. Sir William Hamilton, in an account of a dreadful earthquake which devastated Sicily and Calabria in the year 1783, relates that he saw two girls who were miraculously preserved in the ruins of a house. One had survived eleven entire days, and the other six, totally deprived of food.

It must not escape observation, that the difference between absolute privation of food, and a supply of any portion of it, is incommensurable. The same may almost be said of water; for it materially contributes to preserve life: and hence the difficulties of ascertaining what is truly protracted fasting. The Negro couriers, who traverse the deserts on the western coast of Africa, perform long and fatiguing journeys on about four ounces of food daily. It is a usual custom in such extreme situations of life, that all the lions and the Moors are frequently seen to subsist eight days on three ounces of gum daily, without sensible diminution of health or vigour; and some maintain, that they can fast three days without any inconvenience. The whole store of a courier at his outset, consists only of a pound of gum, a little grilled rice, and several ounces of hard animal jelly, compounded with a fourth of its weight in gum. This substance is decidedly nutritious; for we are told, that when the whole provisions of a caravan had been exhausted in the deserts between Abyssinia and Egypt, a thousand persons subsisted on gum, which was found to form part of the merchandise; and the caravan reached Cairo in safety, without any remarkable accidents from hunger or disease. The compound of the Negro couriers may possess particular qualities in repelling hunger, such as that which, among the primitive inhabitants of this island, is said to have proved sufficient, if equivalent to a bean, for a whole day; and some of the American Indians, who engaged in long excursions, have similar expediencies for blunting the keen sensations which they would otherwise experience. A composition of calcined shells and tobacco juice is formed into a mass, from which, when dry, pills of a proper size, to be kept dissolving between the gum and the lip, are made. Without such artificial preparations, however, long and perilous voyages have been accomplished, without more than a ship's biscuit divided into a number of pieces daily. Captain Jinglefield, and eleven men, of the Centaur man of war which foundered at sea in the year 1782, sailed 800 miles in a yawl, while their sole provisions consisted of a twelfth part of a biscuit for each of two meals a day, and a glass of water, continued.
the sixty-first day of his fast, Dr Willan was summoned to his aid; but the miserable object was then reduced to the lowest state of existence; and although his eyes were not deficient in lustre, and his voice entire, he exhibited the appearance of a skeleton, on which the flesh had been dried; and his personal decay was attended with manifest mental imbecility. Nevertheless with proper regimen, he so far recovered, as in a few days to be enabled to walk across his room; and a clergyman, who had previously been admitted to visit him, had successfully dispelled his religious aberrations: but on the seventh day from the commencement of this system his recollection failed, and he expired on the seventy-eighth from the date of his abstinence. An analogous case has been quoted by the same physician, of an insane person, who survived 47 days on a pint and a half of water daily, during which time he obstinately stood 83 days in the same position. From extreme weakness he lay down during the remainder, still refusing any thing but water; nor did this extraordinary abstinence prove fatal.

Perhaps we should find many examples of fasting for a much longer period, on recurring to morbid conditions of the body; such as that of Janet McLeod, a young Scottish female, who, after epilepsy and fever, remained five years in bed, seldom speaking, and receiving food only by constraint. At length she obstinately refused all sustenance, her jaws became locked, and in attempting to force them open two of her teeth were broken. A small quantity of liquid was introduced by the aperture, none of which was swallowed, and dough made of oatmeal was likewise rejected: she slept much, and her head was bent down to her breast. In this deplorable state, the relatives of the patient declared she continued to subsist four years without their being sensible of her receiving any aliment, except a little water; but, after a longer interval, she began to receive, an sustenance on crusts of bread with milk, or water sucked from the palm of her hand. It is not evident that her convalescence ever was complete, and it rather seems to be inferred that she always remained in a debilitated condition.

After these extraordinary instances chiefly belonging to our own era, to which many more might be added, we shall probably be less incredulous in listening to the accounts of the older authors; and although we may refuse to go to the same extent that they have done, we cannot reject these examples which do not exceed the terms of duration here specified. Yet it is impossible to be too careful of imposture, of which the most decisive illustration is given in the case of Anne Moore, just at the moment of making these observations; and in the earlier remarks transmitted to us, we should be equally slow in receiving what is offered as miraculous interposition of supernatural powers. Mankind, always anxious for distinction, falsely conceive that it is to be gained by deluding the credulous with fictitious narratives. Licetus in his works, published a copious and extended work on this subject, which has now become exceedingly rare. It has cost the author much labour and research, and for the most part it is written in a style more philosophical than common to that age in such subjects. Licetus inclines to make a systematic division of the duration of fasting into different periods, which he designs short, intermediate, and long. The first, he says, is of constant occurrence, is unattended with personal danger, and is limited to three days; the second happens frequently, but life is in hazard, and it embraces an interval within the sixth day. All fasting beyond that time, belongs
to the third division, which he also partitions into three classes, each with four subdivisions. The first commences on the seventh, ninth, twelfth, and fourteenth days of abstinence; the second is limited by the twentieth, thirtieth, fortieth, and sixtieth day; the third commences with the third month, and includes the sixth, twelfth, and twelfth periods exceeding a year. These rather some arbitrary divisions it is true, but the author supports them by numerous illustrations, to which we must refer in general, instead of citing them in detail.

In regard to the sensations excited by protracted fasting, and its effects on the person of the sufferer; there is a difference resulting from the vigour both of body and mind, to which the influence of climate may be joined, but the most direful and lasting consequences frequently ensue. At first every substance is ravenously devoured, to appease the cravings of hunger; every animal, the most loathsome reptiles, are welcome sustenance; and a paste is baked by the New Hollander, composed of ants and worms, interspersed with the bark of trees. John Lery, who endured the extremity of famine in a voyage to Brazil, emphatically declared, that a mouse was more prized in the ship than an ox had been ashore; and he also informs us, that three or four crowns were paid for each. The natives of New Caledonia swallow lumps of earth to satisfy their hunger, and all the literature, continually increasing in tightness, around the abdomen. They seem to do so with impurity, although the custom of eating earth in Java, which is done to reduce personal corpulence, is slowly but invariably destructive. Last of all, recourse is had to human flesh, instances of which have occurred in all countries of the habitable world, on occasion of famine from sieges, shipwreck, or the failure of expected crops of grain.

Diminution of size, and the rapid prostration of strength, are almost immediately consequent to protracted abstinence. The extremities of the natives of New Holland and the Andaman islands, are of dimensions greatly inferior to those of people accustomed to ample supplies of food. The persons of the Arabs of the desert want that rotundity and development which characterizes mankind accustomed to abundance of food. Uncommon emaciation ensues; the inhabitants of the former country, "in times of famine, resemble so many walking skeletons, ready to satisfy their hunger, and the literature, continually increasing in tightness, around the abdomen. They seem to do so with impurity, although the custom of eating earth in Java, which is done to reduce personal corpulence, is slowly but invariably destructive. Last of all, recourse is had to human flesh, instances of which have occurred in all countries of the habitable world, on occasion of famine from sieges, shipwreck, or the failure of expected crops of grain.

“When the rising sun,” says Minasi, “shines from that point whence its incident ray forms an angle of about 45 degrees on the sea of Leggio, and the bright surface of the water in the bay is not disturbed either by the wind or the current, the spectator being placed on an eminence of the city, with his back to the sun, and his face to the sea; on a sudden there appears in the water, as in a catoptric theatre, various multiplied objects; vix. numberless series of pilasters, arches, castles well delineated, regular columns, lofty towers, superb palaces with belvederes and windows, extended valleys of trees, delightful plains, with herds and flocks, armies of men on foot and horseback, and many other strange figures, in their natural colours, and proper actions, passing rapidly in succession along the surface of the sea, during the whole of the short period of time while the above mentioned causes remain.

But if, in addition to the circumstances before described, the atmosphere be highly impregnated with vapour and dense exhalations, not previously dispersed by the action of the wind and waves, or rarefied by the sun, it then happens, that in this vapour, as in a curtain, extended along the channel to the height of about four or five-and-twenty feet, and nearly down to the sea, the observer will behold the scene of the same objects not only reflected from the surface of the sea, but likewise in the air, though not so distinct or well defined as the former objects from the sea.

Lastly, if the air be slightly hazy and opaque, and at the same time dewy, and adapted to form the iris, then the above mentioned objects will appear only at the surface of the sea, as in the first case, but all vividly coloured or fringed with red, green, blue, and other prismatic colours.”

Minasi divides these phenomena into three classes; the marine morgana, the aerial morgana, and the prismatic morgana; and he endeavours to prove, that all the appearances are representations of the objects upon the two coasts. He considers the sea as an inclined speculum, on account of the rapid current which runs through the straits; and he supposes it to be divided into different planes, by the contrary eddies which take place when the current changes its direction. He ascribes the aerial morgana, to the refractive and reflective power of effusive suspended in the air.

Many other phenomena of a similar kind, have been long observed under the names of Looming and Mirage. In our article Atmosphere, we have mentioned a very singular phenomenon observed by Dr Vince of Cambridge; and Dr Buchan has described another in Nicholson’s Journal, vol. xiv. All these phenomena obviously arise from the rarefaction of the air in the neighbourhood of the surface of the sea, in consequence of which, a distant object appears to be depressed instead of elevated by the refraction; and it is sometimes seen both depressed and elevated, one of the images having in general an inverted position. Dr Wallaston has investigated this subject with much ingenuity, and has shown, that this class of phenomena may be imitated, either by viewing a distant object along a red hot poker, or through a saline or saccharine solution, with water and spirit of wine floating upon it. See Nicholson’s Journal, vol. i. 4to. and vol. xiv. page 340, &c. Wallaston, Phil. Trans. 1798. Gilbert’s Journal, vol. xiv. p. 163. Dr Thomas Young’s Natural Philosophy, vol. i. p. 441, 442. FAVERSHAM, is a market-town of England, in the county of Kent, situated on a navigable river, which communicates with the river Swale. The four streets of which it is composed form an irregular cross, having the guildhall and market-place at the centre. Many of the houses are large and handsome, and the streets are well lighted and paved.

The church, dedicated to St Mary of Charity, is supposed to have been built about the time of Edward I. It is spacious and handsome, and is built of flint in the form of a cross, the angles being formed of stone. It consists principally of a nave with aisles, transept and chancel, and there is at the west end a light tower with pinnacles, and terminated by an octagonal spire 73 feet high. The interior of the church underwent a thorough repair in the year 1755, from the designs of Dance. The tower and spire were erected since that time. The church is 160 feet long and 65 broad, the length of the transept 124 feet, and its width 46. There are no galleries in the church; and the organ, which cost above £400, is placed in a niche formed by the walls of the belfry.

The guildhall, or market-house, was built of timber in 1594, and has an open space between the pillars beneath. There is here a free grammar school, founded by Queen Elizabeth, and endowed to the annual amount of £290. There are also two small charity schools, established in 1746, and supported chiefly by voluntary subscriptions, for instructing and clothing 12 poor boys, and 12 girls. There are also almshouses, and other good benefactions, for the poor. The buildings of the celebrated abbey of Faversham, were once extensive and numerous. The two entrance gates remained till about 47 years ago, when they were taken down. Nothing now remains but the outer walls of the precincts, to point out the site of the abbey.

The manufacture of gunpowder is carried on to a great extent in the vicinity of Faversham, under the superintendence of a branch of the ordnance. This manufacture is supposed to have been established before the time of Elizabeth. The works were purchased from individuals by government in 1760, and were soon after rebuilt in a safe and substantial manner. The different mills and storehouses are principally situated on the stream that flows from Ospringe. They are constantly at work night and day, the men relieving each other in parties. The quantity of powder manufactured annually, amounts to between 12,000 and 13,000 barrels, which gives employment to about 400 individuals. The mills were blown up in 1781, by the explosion of about 7000 lbs. of powder. The noise was heard at 20 miles distance.

The oyster fishery is the principal source of the trade of Faversham, more than 200 families being supported by it. Before the last war, Faversham oysters were annually exported to Holland to the amount of £3000 or £4000 annually. Besides the coasting trade, Faversham supplies London with great quantities of corn, hops, cherries, apples, and oysters.

The following is the statistical abstract for the parish in 1811, including the out-liberty.

FELICUDA, (anciently called Phoenicina), is an island on the north coast of Sicily, in the Mediterranean, and one of the most western of the Lipari or Eolian isles. It lies 23 miles west of Lipari, in East Long. 14° 21’, and North Lat. 38° 34’, and is about nine miles in circumference. The lava which forms the shore, and the pumice, glasses, and enamels found every where in the fields, are proofs of the operation of fire in the formation of Felicuda. At a distance the island presents the appearance of a number of eminences heaped around the sides of one central mountain, which rises half a mile above the level of the sea. The summit of this mountain resembles a truncated cone, and includes a hollow 40 feet deep, and about 2640 in circumference, called the Ditch of Fern, which is now in cultivation. It is supposed by Spallanzani to have been anciently the crater from whose lava the island was formed. The soil is composed of half pulverulent tufa, resting on lava. There is also a small isolated hill, to the south-east of the principal mountain, and about half its height. It has the appearance of a broken cone, truncated at the top, where it forms a hollow narrowing towards the bottom, and containing pieces of lava imbedded in earthy crust: the exterior of the hill is lava.

Though yet unprovided with a regular harbour, Felicuda, two bays, the one on the south, the other on the north-east side of the island, by one or other of which a landing may easily be effected, in any direction of the wind.

The shore is almost wholly composed of various lavas: those in the north-east bay have for their base a light grey felspar; they include needles of black and fibrous scoria, with small portions of white semitransparent felspar. In many parts they resemble honeycomb, from the depth and regularity of their cavities, the production of which has been ascribed to the action of gas, when the lava was in a state of fusion. About a hundred and fifty paces to the left of the bay stands a fine rock of prismatice lava, 30 feet high. From the top downwards it is perfectly smooth, to about 12 feet above the surface of the sea, where it begins to assume the prismatic form, dividing into a number of three-sided prisms, and continuing this form under water. The base of this lava is an extremely compact iron-coloured hornstone. It contains a great number of small rhomboidal schists, with some grains of amorphous felspar. A little farther to the left, is the Grotta del Bore Marino; the entrance is 60 feet in breadth, and above 40 in height: it forms a kind of porch, which conducts to a hall 200 feet long, 120 broad, and 65 in height. It is formed in the lava of the shore, whose base is a light porous scoria; it is of a grey colour, interspersed with white shining rhombolid felspars, and magnetic at the distance of half a line, but its power is increased by fusion: like the rock already mentioned, it separates into prisms before reaching the water. Beyond this cavern is a high precipice, which descends into the sea, and is composed of many alternate beds of lava and tufa. Spallanzani counted eleven of each. The remaining part of the shore consists chiefly of prismatice lavas, having for their base the hornstone and scoria in the mass.

The lavas of the interior are of three different kinds, of two of which the base is hornstone, and of the third scoria. They are all very compact, and do not present any of those tumours and inequalities which occur in lavas of more recent formation. The tufas are in general of a light spongy nature, pulverulent and argillaceous, and readily absorb water. In them are found the glasses and pumices before alluded to. The glasses occur in small pieces, enveloped in the tufa. Some of them are beautifully transparent, others are of a grey colour, and some are almost quite opaque: the furnace converts them into a vitreous froth. The pumices are in great quantity, and always in very small detached pieces. They are of two kinds: the one light and porous, the other entirely without pores, of a smooth fracture, and of considerable weight and compactness. The prevailing colours are red, yellow, and ash-grey. All of them abound with very brilliant scales of vitreous felspar, and in the furnace contract into a shining black enamel, interspersed with the whitish scales of the felspar.

The climate of Felicuda is bracing and healthy; the climate.
air is remarkably pure, and seldom contaminated with fogs or vapours; the soil is scanty, and consists entirely of pulverised tufa. The island, however, abounds in vines, which afford an excellent wine. It has also Indian figs, and some olive trees, and gives a tolerable crop of wheat and barley. The value of the total produce, including that of the vintage, was estimated by Spallanzani at 4000 Neapolitan crowns. Its animal productions are not more numerous than those of the vegetable kingdom. Of amphibious animals, Spallanzani only met with the grey and green lizards, (the Lacerta agilis of Lin.) There is not a serpent on the island, nor indeed on any of the group, owing, it is thought, to the paucity of these insects, and other small animals on which they feed.

Felucita contains 650 inhabitants. They are poor, laborious, and happy. Their poverty, indeed, which exempts them even from taxation, gives them at first sight the appearance of extreme wretchedness; but a nearer view opens a scene of unambitious and cheerful tranquillity, which even in its highest anticipations scarcely looks beyond the wants of nature. Their houses are mere hovels, rudely constructed of blocks of lava, and seem hung like the nests of birds to the precipitous cliffs of their mountains. This singular custom was first occasioned by the frequent predatory attacks of the Tunisian corsairs, with which the island was formerly much harassed, and which at length compelled the inhabitants to transfer their residence from the lower parts of the island to those declivities of the mountains, which are less accessible to piratical surprise. Their food, in general, consists of wild fruits, and a sort of black barley bread, placed before them in the coarsest dishes, or on the bare ground, on which they are seated to receive it. They sometimes indulge themselves with the luxury of salt fish and pure water. This last article is extremely scarce, there not being a single spring on the island, which makes it necessary to preserve the rain water in cisterns. Few of these people employ themselves in fishing, in which they use the hook and line. Their principal occupation is agriculture; and it is wonderful with what industry they cultivate, and with what attachment they cling to the wretched soil, which thus scantily repays their ever-patient exertions. "They would not exchange it," says Spallanzani, "for the Fortunate Isles." (v)

FELIS. See MAMMALIA.

FELUPOIS, or FELUPPS; a tribe of negroes inhabiting the western coast of Africa, between the Gambia and the banks of the river Casamansa. The whole extent of the territory occupied by them, is about seventy-five miles in length by forty-five in breadth, terminating to the east near the sources of the latter river. It is of great fertility, well wooded, and abounding in rice, cattle, goats, and poultry, with which the traders on the Gambia are copiously supplied. Numbers of tigers, bears, and leopards, inhabit the forests, against which the natives carry on a bold and successful warfare, for the protection of their herds, and sell the skins to negroes of adjoining districts, by whom they are brought to the European settlers.

The Felupps exhibit certain peculiarities in person, manners, and customs, apparently separating them from the rest of the negro tribes by which they are environed.

In stature they are short and stout, but very strong and swift; their skin is coarse, of a deep black colour; and their hair, which they collect on the crown in an erect queue, several inches long, is woolly, and of greater length than that of negroes in general. The beard is allowed to grow, and is collected in like manner, so as to advance in a point projecting some inches from the chin. Their features are fine, bearing greater resemblance to those of the blacks of India than of negroes, but they have a wild and melancholy cast; and the Felupps are said to be of a gloomy, taciturn, revengeful disposition. They hold very little intercourse with their neighbours, and are exceedingly jealous of their own women, who are reputed to possess very few attractions.

These people, in common with other tribes in different parts of the world, cover their face and skin by a kind of tattooing or scarification, with strange and irregular figures. They go almost naked, except for a scanty girdle; and on the wrists, arms, ankles, and thighs, wear tight leather rings or bracelets, so firmly encircling them, that the intermediate flesh rises high above the natural size.

Nothing whatever is known of the religion of the Felupps; but to judge by the number of charms borne about their persons, they are deeply tintured with the superstitions of the African continent. Their language is peculiar, and uttered with great rapidity in a low guttural accent.

In speaking of the manners of these people, it cannot be denied that they are very imperfectly known to Europeans, because they are shy and reserved, and avoid intercourse with strangers. Their language, too, as reputed difficult, and their traffic being carried on by means of a factor or third person, commonly of the Mandingo nation, offers few inducements to acquire it. Besides the articles already mentioned, grain, and livestock, the Felupps bring great quantities of bees wax to the town of Vintain, which stands by a creek, on the south side of the river Gambia, and sell it to Europeans. But the simple savage is always deeply imposed on; for after having departed with part of the covenanted price received from his factor, the latter himself obtains a considerable balance, emphatically designed "cheating money," as the reward of his trouble. The honey collected in the woods is made into an intoxicating liquor resembling mead. This is one principal ingredient at their feasts, where quarrels, terminating fatally, often ensue when the whole party is in a state of intoxication. One singular feature in their manners is now disclosed, intimately resembling what is denominated the price of blood among other nations. Should a man be killed on such an occasion, a deadly feud is created between his relatives and the murderer, which is transmitted even to posterity. The eldest son of the deceased endeavours to procure his father's sandals, which he wears once a year, on the anniversary of his death, until he finds an opportunity of avenging it. The devoted object seldom escapes; and although we are not sufficiently acquainted with the history of the Felupps to define the interval that may elapse, examples are not wanting among tribes practising similar customs, where it is sometimes not less than twenty years. Nay, the two persons at enmity may often be seen almost in contact, while the one knows he is the object of resentment, and the other only awaits the fit moment of exercising his vengeance.

The Felupps, nevertheless, possess many good qualities: they testify the utmost gratitude and affection towards their benefactors; and whatever is intrusted to their charge is preserved with the most scrup-

FEN

The FelOops are, on the whole, a warlike people, and ferocious in hostility, but they do not seek quarrels, and they enjoy good reputation among the neighbouring tribes. Their arms do not differ materially from those of other Africans on the western coast, and are adapted to the warfare to which they are exposed. They are skilful archers, using bows six feet long, and quivers full of poisoned arrows. One quiver is hung on the right shoulder, and another on the haunch. Besides these, five or six lances or assagays are carried in the hand, which they dart with surprising force and precision.

The numbers of this people are uncertain. They have been calculated at fifty thousand, which probably exceeds the truth, and they occupy sixty or seventy villages, the most remote standing in woods near the rise of the river Casamance. But it is difficult to ascertain the numbers of savage tribes, or the extent of their dwellings; and particularly so here, where intelligent Europeans have not had immediate access to them. Though the FelOops shun communication with establishments on the river Gambia, it is said to be otherwise with the Portuguese settlements on the Casamance, for there they are common and familiar with the settlers. It has thence been concluded, with some probability, that their reserve towards other Europeans, originates from the policy of the Portuguese inspiring them with distrust. By thus estranging them, all the advantages of traffic are exclusively preserved. Goberry *Voyage en Afrique*, tom ii. Park’s Travels, p. 12—18. (c)

FENELON, Francis de Salionac de la Motte, Archbishop of Cambrai, was descended from a very ancient and illustrious family, and was born in the castle of Fenelon, in Perigord, August 6, 1651. He was of a weak and delicate constitution; and, until the twelfth year of his age, was brought up under his paternal roof. He was the child of his father’s old age, and his early amiable dispositions rendered him the object of his utmost affection and anxiety. There was nothing remarkable in the mode of his education, which was entrusted to the care of a private preceptor; but, in a few years, he acquired under this instructor a more extensive knowledge of the Greek and Latin languages, than is usually found at so tender an age; and to this circumstance has been chiefly ascribed the perfection of style, which was discernible in his earliest productions. When he was twelve years old, he was sent to the University of Cahors, which was not very distant from the residence of his family, and where he completed his studies in languages and philosophy. His uncle, the Marquis Antoine de Fenelon, a lieutenant-general in the army, and a nobleman of superior understanding and of sound religious principles, having taken a warm interest in his nephew’s progress, sent for him to Paris, and placed him at the college of Plessis, where he commenced his studies in theology, and where he soon distinguished himself so much by his attainments, that he was permitted to preach in public at the age of fifteen. But his wise and discerning relative, rather alarmed than gratified by the encomiums which this premature appearance had excited, and anxious to secure his nephew’s inexperience from the snares of youthful vanity, placed him at the seminary of St Sulpice, under the care of its learned and pious superior M. Tronson. From the example and instructions of this excellent person, the youthful Fenelon derived his relish of those clerical virtues, of which he afterwards exhibited so perfect a pattern; and received those impressions of elevated piety, by which he was so eminently distinguished during the whole course of his life. When he was scarcely sixteen years of age, he formed the determination of devoting himself to the missions in Canada, where the seminary of St Sulpice had a considerable establishment; and neither the influence of his tutor, nor the remonstrances of his friends, were able to shake his purpose. But at length his uncle, the bishop of Sarlat, on the ground of his nephew’s extreme youth and infirm state of health, explicitly refused to grant permission for his departure, and ordered him to remain at St Sulpice, that, by longer study and retirement, he might qualify himself for the exercise of the ministry. Having been ordained at St Sulpice, he devoted himself for the space of three years to the diligent discharge of his functions in that parish; and, after that period, was appointed to explain the scriptures to the people on Sundays and festival days. About the year 1674, he was invited by his uncle to Sarlat, and resumed with additional zeal his missionary views, choosing the Levant as the scene of his labours; but his friends succeeded in finding for him a more suitable, yet very similar course of ministration; and, at 27 years of age, he was nominated the superior of an institution for preserving in the faith the newly-converted female Catholics. In this humble employment, which required only the simpler forms of instruction, the more minute details of knowledge, and the milder topics of persuasion, he passed ten whole years in the prime of life; but, while faithfully engaged in these obscure and unhonoured duties, he was acquiring by study and meditation those higher talents which contributed to render him so bright an ornament of the Christian church. Though the Marquis his uncle, with whom he resided, passed his life in religious retirement, yet he retained the acquaintance of a few select friends, to whose notice he introduced his nephew, and in whose society he enjoyed many opportunities of improvement. Among these were the Duke de Beavilliers, who was afterwards governor to the Duke of Burgundy, and the celebrated Bossuet, who held the situation of preceptor to the Dauphin. He speedily recommended himself to the esteem and confidence of that distinguished prelate; and profited by his instructions, while he shared his intimacy. During this period he produced his first work, a treatise on “the Education of a Daughter,” which he wrote at the request of the Duchess de Beavilliers, and which has been rather imitated than surpassed by future writers on the subject. In 1680, he was placed by Louis XIV. at the head of the missionaries, who were sent to Poitou and Saintonge, to convert the Catholic faith the Protestants in these provinces, whose pastors had been driven into exile; and having been allowed to choose his colleagues, and authorized to dismiss the military who had hitherto acted as the apostles of the church, he repaired to the scene of his duties with all the zeal of a Romish missionary, tempered with the spirit of Christian conciliation. But though he was received by the people as a minister of peace, and sedulously removed every instrument of coercion, he perceived that his converts were chiefly influenced by fear, in consequence of the violent measures which were pursued in other provinces; and it would seem, that
his proceedings and progress did not keep pace with the
impatience of his employers. In consequence of
his own request, he received permission to return to
Paris, where he gave an account of his mission to the
king in person; and contentedly resuming his humble
functions among the "Nouvelles Catholiques," he was
more than two years without once appearing at court.
He was too indifferent about his personal interests to
employ the ordinary means of promotion; and even his
unoffending character did not preserve him from the
machinations of envy and malice. He had been
selected for the Bishopric of Poitiers, and his nomina-
tion even sanctioned by the king, but it was revoked
before being made public; and at the earnest applica-
tion of the Bishop of Rocelle, who had witnessed his
fidelity in the Protestant provinces, he was on the eve
of being nominated to assist and succeed that aged pre-
late; but means were found to prevent also the accom-
plishment of this plan. In both these cases, his success
was obstructed by the secret influence of Harlai, arch-
bishop of Paris, who never forgave Fenelon the decided
preference which he had shown for his rival Bossuet’s
friendship, and who is said to have gained his ends by
rendering him suspected of a tendency to Jansenism.
Having published, however, in 1688, his treatise on
the Education of a Daughter, and another on the
Ministry of Pastors, which had both been long ap-
proved by his friends in Manuscript, his merits became
more generally known; and an unforeseen event sud-
denly placed him in a situation, which fully displayed
the superior lustre of his character. His friend, the
Duke de Beuvilliers, having been appointed by Louis
XIV. governor to his grandson the Duke of Burgundy,
and having been allowed to select his own coadjutors
in this important trust, without a moment’s delay, no-
minted the Abbé de Fenelon preceptor to the young
prince. Fenelon, equally free in the choice of those
who were to act under his direction, selected as sub-
preceptors the Abbé de Langeron, Abbé Fleury, and
his own nephew, Abbé de Beaumont; and with these
valuable friends, all men of talents and piety, he enter-
red on his arduous office in September 1688. He had,
indeed, no ordinary task to fulfil, the formation of a
good king to twenty millions of people, and the most
unpromising materials in the character of his pupil.
The young Duke of Burgundy was naturally irritable,
unfeeling, obstinate, proud, impatient of control, the
slave of sensual pleasure, and so furious in his rage,
that "it was sometimes feared," says St Simon, "the
very veins of his body would burst;" yet the powers of
his mind were of the highest order, acute, brilliant,
profound. All who were entrusted with the charge of
this extraordinary youth, acted as with one mind, and
upon the same plan; but Fenelon was the soul, which
animated and directed their joint operations. A detail
of their proceedings would furnish at once an interest-
ing and instructive work; and some idea of the method
pursued may be formed from the Fables and Dialogues
which Fenelon wrote for his pupil, and which were
severally composed at the moment when the young
prince required some fault to be corrected, or some use-
ful maxim to be impressed upon his mind. Several
curious particulars have been recorded by Bausset, but
we have room only to state the result. So great was
the Duke’s proficiency in classical attainments that
his tenth year he wrote Latin with elegance, and was
able to translate the most difficult authors with preci-
sion; and what was more important, his character was
so radically changed by the instrumentality of his pre-
ceptor, that his most fearful vices were succeeded by
the opposite virtues, and he was rendered mild, affable,
humane, patient, humble, and austere towards himself.
It was by religious principle, that the sagacious pre-
ceptor effected so remarkable a transformation; and so
powerful was its influence over the mind of the young
prince, that his most impious caprices were often sub-
duced in an instant by merely pronouncing to him the
name of God.
Fenelon conducted, at the same time, and with equal
attention, the education of the brothers of the Duke of
Burgundy, the Duke de Berry, and the Duke D’An-
jou, afterwards Philip V. of Spain; and it may natu-
really be expected, that the most insignificant rewards
were conferred upon his services. But nothing could
equal the disinterestedness of his conduct, except per-
haps the want of generosity in his employers. When
he entered upon his office, he imposed upon himself
two resolutions; from the observance of which he nev-
ver deviated. The one was, to ask no favour for him-
self; and the other, to ask none for his relatives and
friends. It appears from his letters to his cousin,
Madame de Saval, that, after he had been four years at
court, he possessed no other ecclesiastical revenue than
the small priory of Carencac, which the Bishop of Sar-
lat had resigned to him; and that, by the irregularity
with which his stipend as preceptor was paid, he was
often reduced to the greatest embarrassments. "I am
on the point," he writes to the lady above-mentioned,
"of dismissing all my servants, unless I soon receive
some help. I will not suffer you to make any efforts
for me of your own accord. I shall send back what
you would lend me. I prefer to suffer. Let them for-
ward to me from Carencac as much money as they can,
after having, however, distributed the most urgent
aims; for I would rather live upon dry bread, in
the strictest sense of the word, than suffer the poor
of my benefice to be reduced to the extremity of
want." Fenelon, at this very period, enjoyed the high-
est esteem and confidence of Madame de Maintenon,
by whose influence he might easily have supplied his
wants, and acquired his promotion. In the year 1694,
however, the king himself attended to the just claims of
a servant, in whose behalf he received no solicita-
tions; and, with apologies for the delay, communicat-
ed to him in person his nomination to the Abbé of St
Valery. In 1698, he had been admitted a member of
the French Academy, and was daily rising in reputa-
tion as a writer of eminence. But, while emoluments
and honours were at length rewarding his merit, a
storm was beginning to gather, which clouded his fu-
ture days. The celebrated Madame Guyon, who in
1688 had been imprisoned, on account of her heretical
notions, in a conven near Paris, had been released by
the interposition of Madame de Maintenon, and by her
introduction to Fenelon, who had expressed a correspon-
dence of sentiments with her general doctrines of di-
vine love. Several ecclesiastics, alarmed by the in-
creasing influence of her tenets, united, and were part-
ly commissioned, to confer together on the subjects, and
to disclose the opinions of the church on the difficult
points which it involved. These examiners, at the
head of whom was Bossuet, met at the residence of
M. Tronson, the early and attached friend of Fenelon;
and Fenelon himself, when he was concerned in the result,
was frequently consulted respecting the sentiments of other writers on the
question. In the mean time, before his supposed errors
were made the subject of any enquiry, he was nomi-
nated, in 1695, to the archbishopric of Cambrai, and
gave a striking instance of his disinterestedness of char-
acter, and disapprobation of pluralities, by immedi-
ately resigning the Abbey of St Valery. He was re-
quired by the King still to retain his situation as pre-
ceptor, and to reside at Versailles three months of every
year, as the laws of the church allowed, while during
the other nine he should communicate directions for the
education of his pupils. Searcely, however, had he
arrived at Cambrai, when he heard that Madame Guy-
on was arrested; and at once perceived that her en-
terfaces were powerful, and that their hostility might ex-
tend to himself. Her imprudences had irritated Bos-
suet to adopt the harshest measures against her; and
Fenelon's reluctance to concur in the same severe treat-
ment and sweeping censures, rendered him an object of
suspicions to many of his ecclesiastical contemporaries,
and particularly estranged from him his former
familiar friend, the Bishop of Meaux. Having pledged
himself, in the course of the various discussions which
took place, to give a public declaration of his own sen-
timents, he wrote his "Maxims of the Saints," which
he submitted before publication to the Cardinal de
Noailles, to M. Tronson, and to M. Perot, a Doctor of
the Sorbonne, an acute scholastic theologian, who had
been one of the examinators and censurers of Madame
Guyon, and who had long been devoted to Bossuet. With
a docility, which extended their admiration, he altered
every passage to which they objected; and received
their joint declaration, that his book was correct and
useful. No sooner, however, did it appear, in 1697,
than it was denounced as heretical; and a scene of al-
most inexplicable persecution commenced against him,
under the conduct of Bossuet, who personally accused
him of fanaticism to the King, and determined to be
satisfied with nothing less than extorting from him an
absolute recantation. The principal question in the
controversy was, that Fenelon maintained the existence
of a pure and disinterested love towards God; while
Bossuet taught, that this love should always have for its
fruit the love of celestial happiness. The Archbishof of
Cambrai resolved also to submit his work to
the decision of the Pope; and he made this appeal with
the full permission of the King. But this would not
satisfy the requisitions of his enemies; and, from an
amiabie desire of conciliation, he entered into a variety
of personal discussions and explanations, of which his
opponents availed themselves to effect his disgrace at
court. He received a peremptory order to retire to his
diocese; and was, at the same time, refused permission
to plead his cause in person at Rome. His most val-
uable friends retained their attachment to his person
in defiance of all considerations, either of fear or flatter-
ny; and the young Duke of Burgundy, having in vain
endeavoured to prevent his exile, prevailed at least,
thoarough this favour was soon revoked), that he should
be allowed to retain the title of his preceptor. Inno-
cent XII. was very desirous to settle the affair in the
most conciliatory manner; but, in compliance with the
requisitions of Louis XIV. he appointed ten examinators
of Fenelon's work, five of whom voted in its favour.
The Pope himself was secretly disposed to befriend the
accused Archbishop, and is said to have expressed his
personal opinion in these words: "The Archbishop of
Cambrai has erred from an excess of love to God; the
Bishop of Meaux has sinned from a want of due love
to his neighbour." It has also been said of the two
characters, "L'un prouve la religion l'autre la fuit
aimer." But a fresh remonstrance from the King of
France prevailed with the Pontiff to refer the examina-
tion to the assembly of Cardinals; and, after a struggle
highly honourable to the friends of Fenelon, a formai,
but moderate, condemnation of his book, was issued
from the court of Rome in 1699. During the whole
course of this enquiry, the mildness and serenity of
Fenelon formed a striking contrast with the asperity
and rancour of his enemies; and, when he heard of
his sentence, as he was ascending the pulpit on the
day of the Annunciation, instantly changing the plan
of the discourse which he had prepared for that occa-
sion, he delivered a sermon on the duty of passive
obedience, which drew tears of admiration from his
hearers. Actuated by a principle of religious resigna-
tion to the will of God, and love of peace towards his
enemies, he published a formal submission to his sen-
tence. His conduct commanded universal admiration,
and the Pope was so touched with his meekness, that
he wrote to him a letter with many expressions of re-
spect. In the general feeling of approbation which
the whole nation entertained towards the Archbishop,
it was expected that he would again be recalled to
court, and reinstated in his former functions. But the
strongest antipathy against him now appeared to have
possessed the minds both of the King and of Madame
de Maintenon; and all the circumstances of his con-
duct concur to confirm the suspicion that there existed
some secret and more powerful cause of his late per-
secution than his theological opinions. Their refusal to
authorize his return to Versailles, has been ascribed to
the publication of "Telemachus," which a servant of
Fenelon's had, without his knowledge, first circulated in
manuscript, and afterwards sold to a printer at Pâ-
ris. This admirable production was denounced by
the court as a satire upon the government of Louis
XIV.; and the utmost exertions were made to suppress
it for ever. In this opinion, though solemnly disclaim-
ed by Fenelon, Madame de Maintenon coincided; and
whatever had been the intention of the author, the
king could not but feel that his maxims were completely
contradictory of those by which he had been guided.
The avidity with which it was pursued, and the approbation
which it received in every nation of Europe, expressed
at least an implied condemnation, if not of Louis him-
self, yet of the political principles by which his reign
had been directed. There are strong evidences, how-
ever, of an earlier and more inveterate dislike towards
Fenelon, in the heart of the favourite Madame de Main-
tenon, and to which his future disgrace may be con-
idered as principally owing. That lady, not satisfied with
being the mistress, aspired to become the wife of Louis;
but the king's confessor, Father la Chaise, referred the
point to the archbishop of Cambrai, as the ablest casuist
at court. His opinions were hostile to the hopes of Ma-
dame de Maintenon; and, from that moment, his ruin
was meditated. But whatever may have been the im-
mediate cause of that avowed or secret hostility to
which he fell a victim, there can be little doubt that he
had become an object of undefined antipathy to the in-

* These two opinions, apparently so opposite and incompatible, are most ingeniously and satisfactorily reconciled by Bishop Horsley in his 2d Sermon on Phil. iii. 15. — See his sermons, vol. iii. p. 3-9.
† See Guardian, vol. i. Nos. 46, 47, 49; and Voltaire's Hist. de la suite de Louis XIV.
FENELON.

habitants of Versailles; that the unbending integrity of his political morals, and the undeviating purity of his Christian standard, could never have coalesced with the maxims and manners of that unprincipled court; and that, sooner or later, though Madame Guyon had never existed, he must have been compelled to withdraw from the scenes of public intrigue. But the persecution to which he was subjected, only served to proclaim the virulence of his enemies; and his banishment from court, only afforded an opportunity of displaying the virtues of his character as a Christian pastor, in a manner of life at Cambrai, was retired, peaceful, and uniform in a remarkable degree. He rose early, as he had been accustomed from his youth, and performed mass every day in his chapel. He dined at noon, according to the practice of those times, and partook only of the simplest food. All the ecclesiastics of his household were admitted to his table, where he promoted cheerful conversation, while he preserved the most decorous behaviour. After dinner, he dispatched the more formal business of his diocese; and unless he was induced by the weather, or called in duty, to go abroad, generally retired till half past eight o'clock. About nine, he appeared at supper, when he ate nothing but an egg or pulse; and about ten, his domestics were assembled in the principal room, where an almoner read the evening prayers, and the archbishop pronounced the benediction. The only recreation in which he indulged, was walking; and he took great delight in the placid views of nature, the pious meditations when alone, and the pleasing conversations with his friends, which he enjoyed amidst these rural scenes. In the course of his walks, he would sit down upon the grass to converse with the peasants whom he met, or would visit them in their cottages, to offer the consolations which they required, and would often accept their invitation to place himself at their table, and partake of their homely meals. He preached regularly during Lent in some of the churches of Cambrai; and there was not a single parish or town in his diocese where he had not made a personal visit, and publicly instructed the people. Even the descollations of war did not interrupt his assiduity in the duties of his office; and while his diocese was in the possession of the allied armies of Marlborough and Eugene, he was not only permitted, without molestation, to visit every quarter, but protected by escorts, and received with honours wherever he appeared. When they were informed that any of his property was in their neighbourhood, they placed a guard for its preservation; and the towns and villages under his jurisdiction, became asylums to the inhabitants of the surrounding country. In 1711, when the allied armies approached within sight of Cambrai, the little town of Chateau Cambreis, the principal domain of the Archbishop, was guarded by a detachment of Marlborough's soldiers; but perceiving that as his own forces were in want of provisions, he should no longer be able to prevent them from seizing the stores of grain which it contained, and which the neighbouring inhabitants had deposited there under the protection of Fenelon's name, he informed him of the necessity of leaving it, and directed the almoner to whom he had conveyed it to the outposts of the French head-quarters. The worthy prelate availed himself of the security granted to his property, and the safe conduct provided for his person, to furnish relief and consolation to the suffering people under his care. His progress was attended with a temporary suspension of the horrors of war, and the season of his pastoral visits, observe one of his biographers, might justly have been denominated "the trace of God." He opened his granaries to feed the soldiers of his king, and afforded an asylum to the wretched wanderers, whom hostilities had deprived of a home. When his own residence could no longer afford them accommodation, he hired houses for their reception, and often distributed their food with his own hands. He made frequent excursions in order to recover their effects; and even sought from his own purse, the contributions levied by the French government on the curates of his diocese. The French courtiers who served in the army which defended Flanders, carefully avoided him, and even sought to please their superiors by shewing contempt for his character; but his pupil, the Duke of Burgundy, still retained for his preceptor all that affection and respect which his virtues had inspired; and in the first letter which he was permitted to write to him, dated in 1701, strongly expressed the continuance of his esteem, and the disgust with which he had regarded the treatment to which he had been exposed.

When passing through Cambrai in 1708, to take the command of the army along with Marshal de Boufflers, he obtained permission to visit the Archbishop, but only upon condition that a third person should be present. Their interview was therefore short, and their conversation restrained; but, with a voice and manner full of meaning, the Duke said before his departure, "I know what I owe you; you know what I am to you." This excellent prince, who, by the death of the Dauphin, had become heir-apparent of the throne of France, died on the 18th of February 1712; and for many days the anguish of Fenelon's mind was so great, as to alarm his friends with apprehensions for his life. When he received the afflicting intelligence, the only words which he uttered were these, "Every tie is snapped, and nothing now holds me to the earth." Yet his resignation to the will of heaven was unreserved; and he was known to have declared, "If there needed no more than to move a straw to bring him to life again, contrary to the divine pleasure, I would not do it." Nine months after this calamitous event, the Duke de Chevreuse, one of his most intimate associates, was carried to the grave; and in 1714, the last of his early friends, the Duke de Beauvilliers, finished the journey of life. The good Archbishop, enfeebled in body, and overwhelmed with afflictions, survived only four months. In the beginning of the year 1715, he was seized with an inflammation in his lungs, accompanied with continued fever. He anticipated the event, and appeared utterly indifferent to all sublunary things. During the continuance of his illness, which lasted seven days, and occasioned him extreme suffering, he was wholly engaged in listening to the reading of the sacred scriptures; and shewed peculiar interest in attending to the last verses of the fourth, and the first nine of the fifth chapters of the second epistle to the Corinthians. He died in the 64th year of his age, on the 7th of January 1715.

In the character of Fenelon, there appears an extraordinary union of intellectual greatness and of moral excellence. The governing principle of his mind and conduct was the pure and fervent, which preserved his integrity uncontaminated amidst the snare of a licentious court, and his affections undebased by the superstitions of a corrupted church. But his piety, while unequalled, was of the most conciliating and attractive nature; and his talents, scarcely less unrivalled, were exerted with a degree of modesty and affability, which are not often found to
accompany superior endowments. This, indeed, may be considered as the characteristic feature of his mind, that it was compounded of a variety of the rarest qualities, which are so seldom found united in one individual, as to be thought utterly incapable in their very nature. Learning, enlivened by genius, tempred by humility, consecrated by devotion, supported by inflexible integrity, crowned by mild benevolence, and graced by attractive manners; this is more like a character which imagination might draw, than human nature realize; yet such, by the testimony of his contemporaries, and by the acknowledgment even of his enemies, was the character of Fenelon. So fascinating was the charm of these combined attractions, that, in the words of the Duke de St. Simon, "il fallait faire effort pour cesser de le regarder;" and he obtained so irresistible an ascendancy over every one who approached him, that all his friends, however exalted in rank, or distinguished by talents, became in a manner his disciples. "The Archbishop of Cambrai," says the Chancellor D'Aguëseu, "was one of those uncommon men, who are destined to give lustre to their age, and who do equal honour to human nature by their virtues, and to literature by their superior talents. He was affable in his deportment, and luminous in his discourse; the peculiar qualities of which were a rich, delicate, and a powerful imagination, but which never let its power be felt. His eloquence had more of mildness in it than vehemence; and he triumphed as much by the charms of his conversation, as by the superiority of his talents. He always brought himself to the level of his company. He never disputed, and appeared to yield to others at the very time that he was leading them. Grace dwelt upon his lips; he seemed to discuss the greatest subjects with facility, the most trifling were ennobled by his pen; and upon the most barren topics he scattered the flowers of rhetoric. A noble singularity pervaded his whole person; and a certain undefinable and sublime simplicity, gave to his appearance the air of a prophet. The peculiar but unaffected mode of expression which he adopted, made many persons believe that he possessed universal knowledge as if by inspiration; it might indeed have been almost said, that he rather invented what he knew than learned it. He was always original and creative; imitating no one, and himself inimitable. The same man who could ascend the pulpit of a country church, to preach to the Flemish peasantry in a language suitable to the simplicity of their manners, and to the weakness of their understandings, and afterwards descend to explain the catechism to children, shewed himself capable of conducting the concerns of a kingdom. When the affairs of Louis XIV. were in a state of derangement approaching to ruin, the Archbishop of Cambrai generously rendered him the most valuable political assistance. Amidst the labours of his diocese, he applied himself to devise measures for re-organizing the cabinet, and repairing the resources of France, and displayed all the promptitude and sagacity of the most experienced statesman. He even contrived in some degree the military operations of the Duke of Burgundy, whose errors as a general had made him unpopular; and, in short, proved himself fully capable of apprehending and illustrating whatever subject presented itself to his consideration.

Of his writings we have left ourselves little room to give a detailed account; but they are such as must render his name immortal, and contribute essentially to the improvement of the human race. A fire, which consumed his palace at Cambrai in 1697, destroyed many of his most valuable manuscripts, especially those which were connected with the education of his royal pupil, and upon which he had employed the best years of his life, - an event which, for a moment the habitual serenity of his mind, but which the friends of religion and of literature can never cease to deplore.* His Treatise on the Education of a Daughter, published in 1687, though not originally intended for the public, may be considered as a compendium of the most useful precepts on the subject, expressed with the greatest simplicity and precision. His Treatise on the Ministry of Pastors, published in 1688, is intended to vindicate the spiritual authority of the church of Rome, and is at least written with a degree of candour and temper seldom found in ecclesiastical controversies. His various replies to his assailants on the subject of Quietism, were composed with astonishing rapidity, yet with a perspicuity and precision which seemed to initiate the reader into the most difficult points in theology, and with a subtilty of genius which confounded the talents of Bossuet himself. He wrote many pieces against the Jansenists, especially Four Pastoral Letters, printed in 1704; and his share in this contest is certainly the least amiable part of his conduct. The Dialogues of the Dead were composed for the use of his pupil, and intended to fix upon his memory the real merits of the most distinguished characters recorded in history. They were first published in 1715, after the Duke of Burgundy's death, and without the author's name or consent; and it was not till 1730 that a complete edition was given to the world. The Adventures of Telemachus, which was not originally designed for publication, but entirely for the instruction of the Duke of Burgundy, seems to have been composed between the years 1693 and 1697; and as it appears to have been designed to remain a secret between the preceptor and his pupil, this admirable performance, had not the lucky treachery of a transcriber prevailed, might have shared the fate of the other papers in the young prince's cabinet, which Louis committed to the flames. His Demonstration of the Being of a God, which he published in 1713, is, to say the least, the best book on the subject in the French language. His Letters on Religion and Metaphysics, written to the Duke of Orleans, were published after his death, and are chiefly suited to a member of the church of Rome. His Dialogues on the Eloquence of the Pulpit, were composed in his youth, but never made known during his life, and not published till the year 1718. This production may be pronounced, with Cardinal Maury, to be the best didactic work for preachers, and to be founded upon the principles of nature and good sense. His Lives of the Ancient Philosophers is an excellent elementary work for youth; and a very neat translation, recently published by the Rev. John Cormack, has made it accessible to the English reader. His Œuvres Spirituelles, a collection of letters to his friends, also published after his death, contain many maxims of the most sublime piety, and many excellent rules of conduct in the various circumstances of life. The few sermons which have been printed from the pen of Fenelon, were composed during his youth for particular occasions, and furnish no idea of his usual pulpit addresses. The dis-

---

* Louis XIV. is said to have committed to the flames, with his own hand, all the letters of Fenelon to the Duke of Burgundy, with only one exception, which Madame de Maintenon preserved, and sent to the Duke de Beavilliers.
course which he delivered in 1707, at the consecration of the Elector of Cologne, was adapted to the magnificent of the ceremony, and proved his powers to have rivaled the most eminent orators of his time; but it was his ordinary practice, according to the maxims which he inculcates in his Dialogues on Eloquence, to write nothing more of his sermons than the principal heads—a practice which his astonishing fertility of mind and fluency of expression rendered safe in his hands, but which ordinary men would do well to follow with caution. Those who wish to know more of this extraordinary man, are referred to Querbeut's Vie de Fenton; Ramsay's Hist. de la vie de M. Fenton; Elige de Fenton, par M. D'Alembert; and particularly Baussuet's Life of Fenton, translated by Muford. (q)

FENTON, ELIJAH, an English poet, of some note, was born near Newcastle in Staffordshire, of an ancient family, whose estate was very considerable. But he happened to be the youngest of eleven children, and was therefore necessarily destined to some lucrative profession. Accordingly, he was first sent to school, and afterwards to Cambridge; but doubting the legality of the government, and refusing to qualify himself for public employment, by taking the requisite oaths, he sacrificed his interest to his conscience, and left the university without a degree.

Fenton was thus excluded from the ordinary and regular courses of occupation and emolument, and reduced to the necessity of seeking an uncertain and fortuitous livelihood. The obscurity attending such a mode of life, renders it impossible to trace his varying circumstances, or to discover what means he used for his support. It is certain, however, that he kept his name unassailed, and that his character has never been subjected to any mean or dishonourable imputation.

He was a while secretary to Charles, Earl of Orrery, in Flanders, and tutor to the son of that noblemans. At one time, he was assistant in the school of Mr Bonwicke in Surry, and at another kept a school of his own at Sevenoaks in Kent, where he brought into considerable repute; but was persuaded to leave it, in 1710, by Mr St John, under a promise of some more honourable employment, of which, however, he appears to have been disappointed.

In 1707, he published a collection of poems, which procured him admission to the company of the wits of his time; and his amiable manners made him be esteemed by all who knew him. Although he professed the principles of a non-juror, he zealously employed his pen in the praise of Queen Anne; and very liberally extolled the Duke of Marlborough, when he was at the height of his glory. But his elegant penegries do not seem to have procured him any patronage from the great.

Pope is said to have once placed him in a situation from which he might have derived great advantage. Craggs, when he became secretary of state about 1720, feeling his want of literature, desired Pope to procure him an instructor, by whose assistance he might supply the deficiencies of his education. Pope recommended Fenton, and his choice proved acceptable to Craggs. But the small-pox unfortunately carried off the patron, and put an end to the pleasing expectations of Fenton.

When Pope resolved to engage auxiliaries in the translation of the Odyssey, he distributed twelve books between Broome and Fenton. The books allotted to the latter, were the first, the fourth, the nineteenth, and the twentieth. In what manner Fenton performed the task assigned to him, is well known to the readers of poetry.

In 1729, he exhibited his tragedy of Marianne, to which Southern, at whose house it was written, is said to have contributed such hints as his theatrical experience enabled him to supply. When the piece was shown to Cibber, he rejected it, and insolently advised the author to engage himself in some employment of honest labour, by which he might obtain that support which he could never hope to derive from his poetry. The play, however, was performed at the other theatre; and the petulant judgment of Cibber was practically confuted by general applause. Indeed the representation was eminently successful, and Fenton's profits upon this occasion are said to have amounted to near a thousand pounds.

It was probably after the representation of his tragedy, that he undertook to revise the punctuation of Milton's poems, which, as the author neither wrote the original copy, nor corrected the press, was supposed to be capable of amendment. To this edition, he prefixed a short and elegant account of Milton's life. He likewise published, in 1729, a very splendid edition of Waller, with notes, often useful and entertaining, but abounding too much in liberal quotations from Clarendon.

The latter part of Fenton's life was spent in quiet and easy circumstances. Upon Pope's recommendation, he had been invited by the widow of Sir William Tumbull to educate her son, whom he first instructed at home, and afterwards attended to Cambridge. Having acquitted himself in this business to the satisfaction of his patroness, the lady afterwards detained him, as the auditor of her accounts, at her seat of Easthamstead, in Berkshire, where he died in 1750.

Fenton was large in stature, and inclined to corpulence, which tendency was increased by a sluggish and sedentary mode of living. His moral character stands unimpeached; and his manners and conversation were so amiable and engaging, that all his acquaintance treated him with fondness, and spoke of him with praise. As a poet, he did not discover much inventive genius; but he has a good title to be considered an accomplished scholar, and a skilful versifier.

Pope, who had lived in habits of sincere friendship with Fenton, honoured his memory with the following epitaph:

"This modest stone, which few vain marbles can,
May truly say, here lies an honest man;
A poet blest beyond the poet's fate,
Whom heav'n kept sacred from the proud and great;
To God to lift praise, and friend to learned ease,
Content with science in the vale of peace.
Granted he toke'd an either life, and here
Saw nothing to regret, or there to fear;
From nature's temperate feast rose satisfied,
Thank'd heav'n that he had liv'd, and that he dy'd."

FERDINAND. See SPAIN.

FERRE LA, the name of a town of France, in the department of the Aisne. It is situated near the river Sarre, which runs into the Oise. The town is very long, and contains many excellent houses. It was strongly fortified by Cardinal Mazarine, but is now dismantled. In approaching it from Laon, we pass over a fissure, crossed by a paltry wooden bridge, and enter it by an old gate. A stream, with several mills upon it, runs through the town. On leaving the town for St Quentin,
the writer of this article perceived a branch of the St Quintin canal, where many vessels loaded with coals were lying close to the town. The surrounding country is rich and well wooded. Number of houses 550. Population 2604. (m)

FERGUSON, JAMES, a celebrated lecturer, and writer on astronomy and other branches of natural philosophy, was born at Keith, a small town in the county of Banff, in the north of Scotland, in the year 1710. While his father was teaching his eldest son to read the Scotch Catechism, James was busy in learning the same lesson, without the knowledge of any person, and as soon as the Catechism was unprepared, he studied the lesson which had been taught to his brother, and, on the occurrence of any difficulty, he had recourse to an old woman who lived in the neighbourhood. Some time afterwards, his father was astonished to find James reading by himself. He immediately taught him writing, and, with about three months attendance at the grammar school of Keith, this was all the education which our author ever received. While he was about seven or eight years of age, a part of his father’s roof fell in, and a prop and a lever were applied to an upright spar to raise it to its former place. The facility with which it was effected excited the astonishment of the young mechanic, and led him to think on the means by which it was accomplished. He immediately began to construct levers; he discovered that the power was proportional to the length of the different parts of the lever on either side of the prop. He invented the wheel and axle, by endeavouring to make a lever that would raise bodies to any height; and by means of a turning lathe of his father’s, and a little knife, he was enabled to make models of these different machines. Ferguson afterwards wrote out a short account of these machines, illustrated with figures; and upon shewing it to a gentleman, he was surprised to learn that the same things had been known before, and was much pleased to observe that his own account coincided with what he found in other books.

In consequence of his father’s poverty, James began the occupation of a shepherd, and hence he has been ridiculously represented by Lalande as having been shepherd to the king of England for Scotland.* His nights were now spent in studying the stars, while in the day-time he made models of mills and spinning wheels. Our author next went into the service of a farmer of the name of James Glashan. When his work was over, he went into the fields with a blanket about him, and having stretched a thread with small beads upon it, he slid the beads till they hid particular stars from his eye, and then laying the thread down upon a piece of paper, he marked the stars upon it according to their respective positions. His master at first laughed at this apparently ridiculous occupation; but as soon as he knew the object of it, he not only encouraged him to proceed, but often performed young Ferguson’s work with his own hand, that he might leave him time during the day to make clean copies of his rude planispheres. He soon after received from the minister of Keith a map of the earth, and compasses, ruler, pens, ink and paper, for the purpose of copying it; and his generous master frequently took the threshing flail out of his hands and worked himself, while Ferguson was sitting beside him in the barn busy with his ruler and compasses. Upon his return to the minister of Keith with the copy of his map, he saw a man of the name of Cantley painting a sun-dial, and shewed him the copy of the map. Cantley was butler to Mr Grant of Achoyankey, and appears to have been a man of singular attainments. Ferguson had the good fortune to be introduced to Mr Grant, who invited him to live in his house,—a request with which he gladly complied as soon as his term of servitude was over. Cantley taught him decimal arithmetic and algebra, and they had just begun to geometry, when Cantley left the service of Mr Grant for that of the Earl of Fife, who lived at several miles distance. “Cantley,” says Mr Ferguson, “was the most extraordinary man that I ever was acquainted with, or perhaps ever shall see; for he was a complete master of arithmetic, a good mathematician, a master of music on every known instrument except the harp, understood Latin, French, and Greek, let blood extremely well, and could even prescribe as a physician on any urgent occasion.”

Having received from this extraordinary butler a present of Gordon’s Geographical Grammar, Ferguson constructed a globe from the description which is there given of it, and having verified upon it a map of the world, he was enabled to solve all the common problems in geography and astronomy.

Ferguson next went into the service of a miller, expecting to have sufficient time to study decimal arithmetic and geometry. His master, however, fond of drinking, left him the whole charge of the mill, and almost starved him for want of food. As soon as he had recovered the strength which he had lost by the poverty of his diet, he went into the service of a Dr Young, who acted in the joint capacity of a farmer and a physician, and who promised to instruct him in the medical profession. This new master, however, was as bad as the former one. He never even shewed him one of his books, and overwrought him to such a degree, that at the end of three months he was obliged to leave him in a state of great debility, and without receiving a farthing of wages. This inhuman doctor did not even give him any medical advice, and it was only by medicines from his old friend Cantley, who lived at 12 miles distance, that he recovered his strength.

About that time he constructed a wooden clock, the frame of which was of wood, the hours being struck on the neck of a broken bottle instead of a bell. Sometime afterwards, when a gentleman was riding past his father’s house, he asked him what o’clock it was; and having received a very good-natured answer, he begged of him to shew him the inside of his watch, as he could not conceive how it went without a weight and a string. The gentleman kindly complied with this request, and not only shewed him the inside of his watch, but explained to him very clearly in what manner the box was carried round by the uncoiling of the spring. Ferguson then tried to construct a watch with wooden wheels, and a whalebone spring; but upon putting on the balance, he found that the teeth of the wheels were too weak to bear the force of the spring, although the wheels ran fast enough when the balance was taken off. He inclosed the whole in a wooden case, a little larger than a breakfast cup; but a clumsy neighbour one day looking at the watch, allowed it to fall, and crushed it to pieces with his foot. Ferguson was next employed in cleaning and repairing clocks; and when he was living at the house of Sir James Dunbar of Durn, he painted a map of the celestial and terrestrial globe, upon two large spherical stones on the

FERGUSON.

When Edinburgh, and, perhaps before, he obtained a considerable detail of lucrative employment, and thus began a profession which he followed for 26 years. During his stay of two years in Edinburgh, he took a violent inclination to study medicine, and he forsook for a time all his favourite studies. He then went to the country with a cargo of medicines and plasters, but with a very scanty knowledge of the art, and began to practice medicine at the matriculation of his nativity, which he soon saw, however, that he was an unsuccessful practitioner; and finding that no one paid him for his medicines, he went to Inverness for the purpose of resuming his profession as a painter. During his stay at Inverness, he recommenced his astronomical studies, and after much labour, he invented and completed a machine called the Astronomical Rotula, for exhibiting the eclipses of the sun and moon. Mr Macbean, one of the ministers of Inverness, compared the results given by this machine with the calculations given in the common almanac, and found them nearly the same. At his advice, he wrote to the celebrated Colin M'Laurin, Professor of Mathematics in Edinburgh, and requested his opinion of the new instrument. M'Laurin returned him a friendly answer, and requested from him a drawing of his rotula, that he might examine it, and endeavour to procure a subscription for the purpose of getting it engraved upon copperplates. Mr Ferguson immediately complied with this kind request, and a handsome subscription was obtained through the influence of the Professor. The plates of these machines were engraved and published, and went through several impressions, till the year 1753, when they were rendered useless by the change of style. When he went to Edinburgh, he was received with the greatest kindness by M'Laurin, who shewed him his orrery, but was not able to let him see its construction. Ferguson immediately set to work, and constructed an orrery of wood, which exhibited almost all the leading phenomena in astronomy. M'Laurin was so much pleased with this machine, that he desired Ferguson to read a lecture upon it before the mathematical class. He soon afterwards, in 1748, made a smaller and a neater orrery, having all the wheels of ivory, and he took it with him to London, where it was bought by Sir Dudley Rider.

When he reached London, he began his old profession of portrait painting, amusing himself at his leisure hours with his astronomical studies. He now constructed a simple machine for delineating the moon's path and that of the earth, on a long piece of paper laid on the floor. This machine was shewn to Martin Folkes, President of the Royal Society, who took Mr Ferguson to the meeting of the Society that evening, when he shewed his instrument, and explained the use of it. When the Society was dismissed, one of the members, Mr John Ellicott, a celebrated watchmaker, asked Ferguson to dine with him at Hackney, and upon that occasion, he shewed him that he had invented and constructed the same machine many years before.

In 1747, Mr Ferguson published a dissertation on the phenomena of the harvest moon, with the description of a new orrery with only four wheels. In 1748, he read lectures on the eclipse of the sun that happened on the 14th of July of that year. He afterwards read astronomical lectures on an orrery which he constructed, and which he has represented in the 6th and 7th Plates of his Mechanical Exercises. He then began to construct an apparatus for lectures on mechanics and other branches of experimental philosophy. These lectures were repeated in various parts of the kingdom, and added both to the fame and wealth of our author. In the year 1734, Ferguson published "A brief Description of the Solar System, to which is subjoined an Astronomical Account of the year of our Saviour's Crucifixion, and Likewise an Idea of the Material Universe, deduced from a Survey of the Solar System." In 1756, he published in one vol. quarto, several of his best works, entitled "Astronomy explained upon Sir Isaac Newton's Principles, and made easy to those who have not studied Mathematics." This work was written with such uncommon perspicuity and plainness, that it was translated into the German and Swedish languages, and has undergone no fewer than thirteen or fourteen editions. A new edition of it has lately been published by Dr Brewster, in 2 vols. 8vo, containing an account of all the new discoveries in the science since the time of Ferguson.

About this time Mr Ferguson was introduced to his present Majesty, then Prince of Wales, who attended his lectures, and took great pleasure in conversing with him on astronomical subjects. Mr Ferguson received several presents from the prince, and when he ascended the throne, he allowed him £50 a year out of his privy purse, which was regularly paid to him without any deduction.

In 1760, Ferguson published his "Lectures on Select Subjects in Mechanics, Hydrostatics, Hydraulics, Pneumatics, Optics, Geography, Astronomy, and Dialling," &c. This work, which is perhaps the best and the most useful that he ever wrote, passed through several editions, and contributed more to the diffusion of mechanical knowledge among all classes of people, than all the works that have been written upon these subjects. A new edition of it in 2 vols. 8vo, with an Appendix, containing an account of all the recent inventions and discoveries, was published by Dr Brewster in 1805, and a second edition in 1806.

In 1761, he published his " Plain Method of determining the Parallax of Venus by her Transit over the Sun, and thence, by analogy, the Parallax and Distance of the Sun, and of all the rest of the Planets." In 1765, he was elected a Fellow of the Royal Society of London, and was excused the payment of the usual fees, which had only been done in the case of Sir Isaac Newton, and of that ingenious and self-taught mathematician Mr Thomas Simpson of Woolwich. In the same year he published his "Astronomical Tables and Precepts for calculating the true Times of New and Full Moons, and shewing the Method of Projecting Eclipses from the Creation of the World to A. D. 1800, to which is prefixed a short Theory of the Solar and Lunar Motions." In 1767 he published "Tables and Tracts relative to several Arts and Sciences," and also "A Supplement to the Lectures on Mechanics, Hydrostatics, &c," which is annexed to all the subsequent editions.
Fermanagh. of that work. His "Young Gentleman's and Lady's Astronomy familiarly explained, in ten Dialogues," appeared in 1768, and was reprinted in 1769, under the title of "An easy Introduction to Astronomy, for young Gentlemen and Ladies." This little work has gone through eight editions, and was translated into German in 1771. Madame Genlis remarks, in her preface to the "Tales of the Castle," that this work is so perspicuous, that a child ten years old may completely understand the whole of it. In the year 1770, he was chosen a member of the American Philosophical Society; and, in the same year, he published his "Introduction to Electricity." His "Select Mechanical Exercises, shewing how to construct different Clocks, Orreries, and Sun-Dials, on plain and easy Principles," &c. appeared in 1773, and were accompanied with an account of his life, written by himself. In 1775, he published "Two Letters to the Rev. John Kennedy, containing an account of many mistakes in the astronomical part of his scriptural chronology, and his abusive treatment of astronomical authors." These were followed by a third letter on the same subject. In the same year, he published his last work, entitled "The Art of Drawing in Perspective, made easy to those who have no Knowledge of the Mathematics." This work has gone through several editions, and was translated into French by P. R. Laveque. Besides these works, Mr. Ferguson communicated several papers to the Royal Society, which were printed in the Transactions of that learned body; but as the most important of them were reprinted in his own works, it is unnecessary to give any enumeration of them at present.

Mr. Ferguson had always a weak constitution; and, after struggling against a lingering illness, he died on the 16th of November, in 1776, in the 60th year of his age, leaving behind him an only son, who is still alive, and to whom he bequeathed a very considerable sum of money, which he had made by his lectures and his various works.

FERMANAGH, a county of Ireland, in the province of Ulster. It is bounded on the west by Leitrim, on the north by Tyrone and Donegal, on the east by Tyrone, and on the south by Cavan and Leitrim. This county is of very uneven surface; it abounds in hills, many of them of great height, and boggy; and on the borders of Tyrone and Cavan, and especially of Leitrim, it is particularly mountainous. These high grounds afford a good coarse pasture for young cattle; and most of them are said to be capable of great improvement. But agriculture is not in a flourishing condition; there is a want of enterprize, of skill, and of encouragement. Nothing can shew more clearly the barbarous state of husbandry in this district, than the fact, well authenticated, that so late as the year 1803, it was the practice in some places to plough by the tail! In the northern part of the county, the farms are of a large size, and the high grounds tolerably productive; and though there is but a small portion of the land in tillage, the system of management is superior to what prevails in the neighbourhood. Little wheat or clover is sown. Oats are more common, and so is barley. In some quarters, when calculating the most profitable crop, they estimate four stones of barley, and six of oats, to a gallon of whisky. Potatoes are quite common. In 1809, about 5000 Irish acres were supposed to be sown with flax. In the neighbourhood of Florence-court, the farms consist of from two to 20 acres each, and belong almost wholly to manu

ufacturers. The grazing tenures are from 100 to 300 Fermanagh.

After all, the profits of farming must be considerable, if Mr. Wakefield's information be correct, that "Enniskillen market is attended weekly by about 30 or 40 farmers from the vicinity, whose circumstances enable them to eat meat daily, and to drink port wine." On the superior pasture lands, there are cattle and sheep of a large size. Lord Belmore's sheep at Castle-cool, when fat, weigh 30 lb. per quarter. A considerable part of the county is occupied with dairies. There is a small breed of cows here similar to those in Down.

There are no flocks of sheep: the number of this animal is small, and the breed in general very inferior.

Labour is paid as often in money as in conveniences: the bound labourer generally in the latter. In 1811, the prices of labour, provisions, &c. were as follow: a man, the year round, 1s. and a woman 6d. per day; a carter, per day, 3s. 6d. and if constantly employed, 2s. 6d.; a mason, per day, 2s. 6d.; a thrasher, per day, 1s. 6d., or, by piece-work, from 6d. to 8d. per barrel of oats, 6d. to 10d. per do. of barley, and 1s. 1d. to 1s. 8d. per do. of wheat; a car and horse per day, 2s. 6d.; a saddle-horse per do. 5s. 5d.; a plough per do. 11s. 4d., and, for ploughing and sowing an acre, from 26s. to 36s.; a blacksmith, per stone of work, 1s. 6d., or per day 2s. 6d.; turf, per kish, 2s.; sea-coal, per barrel, 4s. to 5s.; culm, per do. 3s.; line, per do. 1s. 6d. to 2s.; a car, mounted, £4, 10s.; potatoes, per stone, 2d. to 4d.; salt butter, per cwt. £4, 13s. 4d.; fresh do. per lb. 1s.; hay, per ton, £3 to £4; whisky, per gallon, 7s. 9d. to 10s.; strong ale, per quart, 4d.; porter, per gallon, 1s. 3d.; beef, per lb. 6d.; mutton, 7d.; pork, 3d.; lambs, per score, £18 to £22; eggs, per score, 6d.; cheese, per lb. 1s. 6d.; bacon, per do. 6d.; shoeing a horse, 4s.; shoes, per pair, 11s. 4d.; salt, per stone, 1s. 6d.; undressed flax, per cwt. £4, 10s. to £5; wool, per stone, 22s. to 20s.; fowls, per couple, 1s. to 1s. 6d.; wheat, per barrel, £2, 3s.; barley, do. 19s.; oats, do. 13s. 6d.; quartern loaf of wheaten bread, 1s.; flour, 1s. 3d. per cwt. £1, 9s.; 2s. per do. £1, 8s.; 3s. 6d., £1, 4s.; oaten meal, per cwt. £1. 10s.; labour in harvest of hay and corn, per day, 2s. to 3s.; moving grass, per acre, 5s.; rabbets, per couple, 1s. 8d.; milk, per quart, 2d.; corn acre of oats (tith free to the tenant), per acre, £6 to £8; do. meadow (according to weight of grass, do.), £6 to £9; do. potato land, do. £6, 16s. 6d. to £8, 8s.; do. flax, per rood (tith free), do. £2, 5s. to £2, 10s.

Some parts of this county are very bare of trees, but other parts are extremely well-wooded, and upon the whole may be considered as superior in this respect to any district of Ireland. The ash is very common, running along the hedgerows, and on the northern side of Lough Erne appearing like a weed of the country: it is, however, of modern introduction. Beech grows here to a large size. There are also oaks, firs, sallows, and hazels. Elm is seldom raised. At Lough Erne, the yeal grows to an astonishing bulk. The only kinds of wood found in the bogs, are fir, oak, and yew. Besides wood, the inhabitants of this county make use of turf and coal as fuel.

Mr. Wakefield computes the average rental of this county at £1, 5s. per green acre. Of course there is a great variety in the rents of land, arising from quality of soil and other circumstances. At Florence-court, land lets at £1, 10s. per acre: near Enniskillen, it lets at £8, 8s. per corn acre. In general the leases
There are only 18 parishes in the county; 13 of them are in the diocese of Clogher, and the other three in that of Kilmore. The Protestants are to the Catholics in the proportion of two to three. The hostility of the former to the latter is carried to a high pitch of violence. In every respect the Catholics are discouraged and kept down. All the greatest proprietors are Protestants, and members of the established church. The Protestant dissenters are few in number. Sir Richard Harding has an estate of 81 farms, and the tenants in 79 of these are Protestants.

According to Dr Beaufort, Fermangh contains 719 square miles, or 455,298 acres English measure, the length being 43 miles, and the breadth 33. Of these, Lough Erne occupies 76,911. Mr Wakefield makes the superficial contents 694 English square miles. The population of the county is 71,800, and the number of houses 11,969, being six individuals to a house. Excluding Lough Erne, there are about 31 English acres to a house, or 2½ acres to each individual. See Newenham's View of Ireland; Wakefield's Statistical Account of Ireland; Beaufort's Memoir of a Map of Ireland; and Young's Tour through Ireland.

FERMAT (Pier), an eminent French mathematician, who was born at Toulouse in 1596, and died in 1663. He was contemporary with several mathematicians of the first order, among whom may be mentioned Pascal, Des Cartes, Roberval, Torricelli, Huygens, Meziar, Carcavi, Wallis, &c.; and furnished solutions of all the more difficult problems which these illustrious men were in the practice of proposing to one another. His predilection for numerical researches, led him to direct much of his attention to prime numbers, a subject which had been almost entirely neglected since the days of Eratosthenes. In these researches he afforded striking proofs of the superiority of his genius, by the discovery of many general and curious properties of numbers which have no divisors, and such as are composite. The indeterminate analysis also occupied a good deal of his attention; and though Bachet de Meziar had already greatly extended and illustrated the Diophantine problems, his researches were far surpassed, in elegance, simplicity, and generalization, by those of Fermat. When Pascal was engaged at Paris in investigating the nature of figure numbers, Fermat was eagerly prosecuting the same subject at Toulouse, by a different train of investigation; and, indeed, on many occasions, these two great men were frequently led to the same results, by methods of inquiry which had little resemblance to each other. Such interferences in their pursuits, did not, however, weaken the friendship to which the conformity of their studies alone had given birth; and, though they were never personally acquainted, they uniformly did justice to the merits of each other, with a liberality which is unknown to little minds.

Fermat was scarcely more distinguished as a mathematician than as a general scholar; and, like most of the learned men who flourished in the age in which he lived, he cultivated jurisprudence and elegant literature with no less assiduity and success, than geometry and algebra. The universality of his genius, and the extent of his attainments, procured the esteem of his fellow-citizens, and raised him to the dignity of a councillor in the parliament of his native city.

But while we are disposed to admit the originality that characterizes the investigations of Fermat, we cannot acquiesce in opinion with a modern writer of very
high authority, we mean La Place,* who affirms, without any sort of proof, that he was the real inventor of the differential calculus. The controversy on this subject has already been laid at rest; and, as all the contemporary writers were unanimous in ascribing the invention either to Newton or Leibnitz, the most unexceptionable evidence is now necessary, to support the claims of a third person to any share in the merit of the discovery. Fermat, indeed, in some of his investigations, employed methods resembling the fluxionary calculus; and the same thing had been done by Roberval and Pascal, in treating of the properties of the cycloid; but the circumstances which constitute a right to any important invention, must be founded, not upon obscure and indirect hints, but upon a distinct development of its principles, and the actual application of these to the purposes of which they are susceptible of being applied. In this point of view, none of the predecessors of Newton or Leibnitz can come in competition with them; and, without examining the merits of their respective claims, we must still consider them as dividing exclusively the honour of the greatest discovery that has ever been made by human ingenuity.

Fermat wrote dissertations on the following subjects: 1. A Method for the Quadrature of Parabolas; 2. Another on Maxima and Minima; 3. An Introduction to Geometrical Loci; 4. A Treatise on Spherical Tangencies; 5. A Restoration of the two Books of Apollonius on Plane Loci; 6. A general Method for the Dimension of Curve Lines. His Opera varia Mathematica, printed at Toulouse in folio, 1679, contain also several smaller tracts, and a great number of letters to learned men. (A)

FERMENTATION, an intestine commotion, to which certain substances of vegetable or animal origin are, more or less, liable, from the spontaneous reaction of their constituent elements. The process embraces a series of changes of composition, and terminates in the formation of new products, which differ essentially from the original substance, as well as from one another. Fermentation is accordingly divided into three kinds; and to these, epithets have been applied descriptive of the products to which it gives birth, namely, the vinous, the acetous, and the putrefactive. After making some remarks upon the process in general, we shall consider the subject under these three heads.

It appears that no species of fermentation can take place without some portion of moisture, and a certain elevation of temperature. The presence of moisture is necessary, because no chemical action can be displayed by solids, without the intervention of water, to give mobility to their component particles, and allow them to exert their mutual attractions for each other; and hence, vegetable or animal substances which are well dried, and kept free from moisture, may be preserved for many years without suffering any material change in their composition. The degree of heat necessary for fermentation vary with the different kinds of it; but below a certain temperature, the process does not commence under any form, or is effectually checked if it has already begun. Boerhaave imagined that the three kinds of fermentation which we have enumerated, always succeeded each other in the same invariable order; but though this is often the case, it by no means holds universally. Many substances undergo the acetous, without having previously passed through the vinous fermentation; and a still greater number run into putrefaction that never suffer any change analogous to the vinous or acetous processes.

The vinous fermentation has been examined by chemists with a great deal of attention; and v a variety of useful facts connected with the process have been noticed, though the circumstances that may be deemed essential to it are still involved in some degree of uncertainty. It is well known that saccharine matter, in some form or other, passes most readily into the vinous state, and that the product of the fermentation is strongest when the substance which is subjected to the process contains the largest portion of sugar; but it has not been decidedly ascertained whether sugar is the only substance capable of being converted into ardent spirit. When nutritive grains are employed to afford fermented liquors, they are previously exposed, at least in part, to the operation of malting, the object of which is to convert the farinaceous part into sugar by germination. This operation was long held indispensably necessary to render the grain capable of the vinous fermentation; but experience has proved this opinion to be, in some measure, a mistake. Spirit distillers have of late been in the practice of malting only part of the grain, and adding the rest in a mashed or ground state; and they have found it to answer their purpose extremely well, when the latter is used in a greater proportion than the former. It is not a little singular, that when the farinaceous part of the mashed grain is mixed with water, it passes into the state of an acid, without acquiring any vinous quality; but when mixed with a quantity of saccharine matter, it undergoes the vinous fermentation, and yields a larger portion of spirit than the sweet matter alone would have afforded: a fact which seems to indicate, that the matter already in the state of sugar has the property of acting upon the farinaceous part of the grain, and converting it into a similar substance. Mr. Irvine remarks, that "were it not for this property of the farina, great loss would frequently be sustained by the farmers in unfavourable seasons; as grain that has once begun to grow, and whose vegetation has been stopped, can never be made to grow again. Such grain never can undergo any farther malting; when grain has been made to grow in this manner, it can hardly be supposed that the change into saccharine matter is perfect or complete. It therefore would be less proper for the vinous fermentation, and would furnish a smaller quantity of spirit than grain which had been perfectly malted. This grain, however, when mixed with a quantity of perfect malt, and fermented, furnishes as much spirit as if the whole had been in the state of malt. The persons in this trade even prefer it to an equal quantity of malt; for in good seasons, when no such half-malted grain can be got, they take good grain, reduce it to meal, and mix it with their malt, and are satisfied that they obtain more spirits in this way, than from an equal quantity of good malt."

Though sugar, in some modified form, appears to be the only substance capable of the vinous fermentation, certain other substances are necessary, both for the commencement and continuation of the process. A suitable quantity of water must be added to the saccharine matter: if the quantity, however, be in excess, the liquor is apt to pass into the acetous fermentation; and if it be too little, the process goes on difficulty and slowly. When the liquor to be fermented consists...
of a solution of pure sugar, a quantity of yeast is also necessary to excite the fermentation, and make it pass into the vinous state. Nor is the influence of temperature less essential: below 50° of Fahrenheit's scale the vinous fermentation proceeds very slowly; and at the freezing point it is completely checked. Above 70° the process advances too rapidly, and unless it be duly moderated, is apt to pass into the acetic stage.

The nature and action of yeast have been the subject of chemical investigation. Lavoisier ascertained, that, besides the other elements which are usually found in vegetables, it contained a quantity of nitrogen in its composition, and so far evinced a connection with animalized matter. The researches of Pabroni, Thenard, and Seguin have demonstrated that the fermenting property of yeast is owing to the presence of a substance resembling gluten or albumen, which is derived from certain vegetable infusions, capable of spontaneous fermentation.

When circumstances are sufficiently favourable for the vinous fermentation, the liquor, in passing into it, becomes somewhat turbid, and manifests a kind of commotion throughout its whole mass. Air bubbles begin to be separated, and being entangled by the flocculent part of the liquid, occasion a frothy appearance on the surface. In the meantime, the temperature gradually increases, and sometimes requires to be checked. The gas which is disengaged is found to consist chiefly of carbonic acid, mixed occasionally with a portion of hydrogen. At length, the extrication of air, and the intestinal commotion with which it is accompanied, gradually diminish, and the process terminates by the liquor regaining its transparency. If the fermented substance be now examined, it is found to have exchanged its sweet taste for one of considerable pungency, and to have acquired the property of acting as a powerful stimulant on the animal system.

The vinous fermentation depending in a great measure upon the separation of carbon, the process may be conducted without the aid of atmospheric air; and, indeed, it has been found by experiment, that, if the air be excluded, while the gas disengaged by the fermentation is permitted to make its escape, the vinous product is stronger than when the process is carried on in open vessels. In that case, however, as Chaptal remarks, the fermentation advances more slowly.

The products of the vinous fermentation.

The products to which the vinous fermentation gives birth, resemble one another by possessing an intoxicating quality, and yielding, by distillation, a portion of alcohol; but they differ considerably in their strength, colour and flavour. Their differences, in these respects, are owing, partly to the essential oils, and other proximate principles which they derive from the substances submitted to the vinous process, and partly to the manner of conducting the fermentation. They may be considered as of two general descriptions: Wines, properly so called, and the various kinds of ale or beer.

Wines are obtained by subjecting to fermentation the sweet juices of fruits, particularly that of the grape. The products are extremely diversified, and vary in flavour and appearance with the climate, soil, and the nature and culture of the vine, as well as with the manner of carrying on the fermentative process. Hence wines are sweetish, and weaker or stronger, according as the saccharine matter of the grape is more or less abundant, and the fermentation more or less complete; and they are sharp and sparkling, when part of the carbonic acid, which is generated during the process, is retained.

Astringent wines derive their peculiar flavour from the astringent principle contained in the grape from which they are formed. The colour is communicated by the external pellicle of the fruit, and might easily be prevented, if necessary, by removing the husks, before fermentation. Wines of every description contain a certain portion of superatrate of potash, which gradually separates from them, when they are left unmolested; and to this is owing, in a great degree, the improvement of wines by age.

France produces a great variety of excellent wines. For daily use, Fournier prefers those of Burgundy, because all their principles are duly combined, and none of them predominates, so as to communicate a peculiarity of flavour. The wines of Orleans, after being matured by age, resemble those of Burgundy. The red wines of Champagne are highly prized for their excellence and delicacy; though, in some cases, they possess a pungent and sourish taste, from being bottled before the carbonic acid is sufficiently disengaged by fermentation. The wines of Languedoc and Guienne are greatly esteemed, on account of their tonic qualities, particularly when they are mellowed by age. Those of Anjou are strong, spirited, and intoxicating.

The Ilhenish and Moselle wines have a cool, sharp and readily intoxicating. Some Italian wines, such as those of Orvietto, Vicenza, and Larcyn Christi, are well fermented, and resemble the French wines. Those of Spain are in general boiled, sweet, and being but partially fermented, cannot be reckoned wholesome. The wines of Rota and Alicant must, however, be excepted, and are justly considered as useful stomachics. The wines of Portugal have been long in great demand in this country; and, indeed, no wine can be accounted superior to good old port.

The wines formed from other fruits, as currants, gooseberries, apples, pears, &c. are generally inferior to those obtained from the grape. The juices of these fruits abound too much with acid, and too little with saccharine matter, to afford of themselves even tolerable wines; and they must, therefore, be improved by the addition of sugar, before fermentation. The wines from the juices of the apple and pear, denominated cider and perry, contain a large portion of the acids of these fruits, and a considerable quantity of carbonic acid: to the presence of the latter is owing their sharpness and sparkling property. Cherries furnish a very pleasant wine; apricots, peaches, and prunes, afford wines of an indifferent quality.

The nutritive grains, and particularly barley, furnish a fermented liquor of a vinous nature, called ale or beer. The grain, after being converted into malt, is first reduced to a coarse powder in a mill, or bruised between rollers. It is then infused in hot water, at the temperature of about 160° or 170°, and allowed to macerate for a few hours; after which the liquor is drawn off, and a fresh quantity of water is added. The infusion thus obtained, is denominated wort. Before being allowed to ferment, the wort is boiled with some bitter vegetable substance, commonly hops; partly with a view of correcting any ascendant tendency, and partly of improving the flavour of the liquor. To promote fermentation, a quantity of yeast is added to the infusion, after it has been allowed to cool; but the process is usually checked before it has been completely finished, and the liquor is then drawn off. When the object of the fermentation is to obtain a wort for distillation, part of the grain, as we formerly observed, is used in a
FERMENTATION.

Theories of the vinous fermentation.

Lavoisier's theory.

The acetous fermentation is not confined to the products of the vinous stage; for it appears, that some substances not susceptible of vinous fermentation, as fiduci and mucilage, have an ascendant tendency; but the bodies which have passed through that process, as wines, cider, beer, &c., are most susceptible of spontaneous acetication, and the richest and most generous wines furnish the best and strongest vinegar.

The vinous liquors do not readily undergo the acetous fermentation without the assistance of some fermentative principle; and hence, on converting wines into vinegar, a quantity of that substance, in some form or other, is usually added. It is in this way that the lees of vinegar, and casks impregnated with it, decide and promote acetication.

The presence of air is no less necessary to the acetous fermentation. Wines well corked in bottles, and grapes properly closed up in casks, may be preserved a very long time without suffering much change; but if the air be imperfectly excluded, they are gradually rendered sourish, and that, in a greater degree, the more freely the air is admitted. Saussure states, that in this case the oxygen of the air enters into combination with the carbon of the vinous liquor, and abstracts that element from it in the form of carbonic acid. It is probable, however, that a portion of it also combines with the same substance, and contributes to the production of that acid which is found in vinegar.

Seguin's theory.

Seguin has proposed a theory of fermentation which differs considerably from that of Thenard. He is of opinion, that during the process water suffers decomposition; and that its oxygen combines with the carbonaceous part of the yeast to form carbonic acid, while its hydrogen unites with the saccharine matter, and produces the fermented liquor. To this theory it may be objected, that, besides being liable to the difficulty of accounting for the great quantity of carbonic acid extricated by referring it entirely to the carbon of the ferment, a greater weight of alcohol ought to be procured by fermentation than that of the sugar subjected to the process; which is contrary to experience, as little more than half the quantity is obtained. To this it may be added, that alcohol contains less oxygen than sugar. Upon the whole, the hypothesis of Seguin is perhaps less probable than that of Thenard; though in the present state of our knowledge on the subject, it would be easy to suggest various other theories of equal plausibility.

A slight agitation, repeated at intervals, is extremely injurious to fermentation. For this reason, cellars are commonly attended by incessant motion excited by the frequent rolling of heavy carriages, and in some cases by the continual shaking produced by any powerful mechanical instrument, or by the vapors of spirits or volatile oils. By the agitation to which wine is subjected during the process of fermentation, the heat is kept up at this pitch by artificial means, when the temperature of the air is too low. Effects of fermentation.

The general appearances which present themselves in the acetous fermentation, differ but little from those in the vinous. A tremulous motion pervades the whole mass; but this is attended with a less copious disengagement of carbonic acid than in the vinous stage of the process. The temperature rises, and if the quantity of liquor be considerable, sometimes reaches 90° of Fahrenheit's scale. In the mean time a kind of filaments, or streaks, are moving continually in the heart of.
the fermenting mass; these divide, reunite, and at last deposit themselves on the sides and bottom of the vessel. When all these phenomena have ceased, the liquor gradually recovers its transparency, and is found to be converted into vinegar.

We shall now make a few observations on the theory of the process, though on this head we can offer nothing very precise or satisfactory. According to Lavoisier, the spirituous part of the wine, which consists of carbon and hydrogen, is oxygenated and converted into vinegar. This operation, he adds, can only take place with free access of air, and is always attended with a diminution of the air employed, in consequence of the absorption of oxygen." This explanation is too general to be satisfactory; and it does not at all bring into view the action of the ferment. Chaptal has given a theory of the process, which is less exceptionable. "The hydrogen and the carbon, says he, exist in alcohol, and in the extractive principle of vegetables; but hydrogen predominates in the former, and carbon in the latter; so that if we oxygenate them separately, alcohol would furnish plenty of water, and very little acid. The extractive principle would furnish plenty of carbonic acid, and a little acetic acid. But when the two principles are united, and they are oxygenated by any process whatever, water and carbonic acid are then produced, which bring the two principles into the proportions proper for forming the acetic acid."

The vinous and acetic fermentation are confined to a very few substances, chiefly of a saccharine nature: the putrefactive stage embraces a wider field, and takes place in almost every body of a vegetable or animal nature. The vegetable matters which undergo putrefaction most readily, are soluble in water; though those which are but imperfectly soluble, if kept in a moist state, are not exempted from this species of decomposition. This process is promoted by the same circumstances which are favourable to the others, namely, moisture, and elevation of temperature. The presence of air, also, has no less influence on the putrefactive, than on the acetic stage.

The elastic fluids which are evolved from vegetables during the putrefactive fermentation, are combinations of the elements of the vegetable substance, and have for their bases hydrogen and carbon. When the decomposition takes place under water, the hydrogen, by its greater tendency to elasticity, makes its escape, and the residual matter consists almost entirely of carbon. Hence wood, which has been long buried in the beds of rivers, is reduced nearly to the state of charcoal. If the carbonaceous part, however, be exposed to the air, it undergoes a gradual change, and is at last entirely decomposed, by being converted into carbonic acid.

When animal matters suffer putrefaction, they evolve, besides the usual elements of vegetables, a quantity of ammonia. They yield also certain other products which are more peculiar to them, particularly combinations of sulphur and phosphorus; and to these substances must be ascribed, the fetid odour and noxious properties of the gases, which are extricated from them during putrefaction.

Animal bodies scarcely suffer any change when they are well dried, and completely excluded from the air. Even in the warmer climates, beef, which has been effectually freed from its juices, may be preserved a long time without salt; and mutton, which has been sufficiently roasted, and afterwards covered with melted suet, may be preserved in that state perfectly untainted for several months. Animals enclosed in ice, have been preserved for ages without suffering any change. It appears, also, that animal bodies powerfully resist putrefaction, which have been buried in morasses of peat; probably because, in such places, the carbonaceous part of the woody matter being converted into a substance resembling tar, produces upon the animal matter the usual effects of that vegetable product. See Chaptal's Chemistry, vol. iv. p. 510; Murray's Chemistry, vol. iv. p. 397; Fourcroy's Chemistry, vol. ii. p. 302. (a)

FERMOY is a handsome and flourishing market-town of Ireland, in the county of Cork. It is situated upon the river Blackwater, over which there is a good bridge. The town is regularly built, and contains several elegant public buildings, viz. a handsome church, a large school house, a market house, a sessions house which serves both for a theatre and an assembly room, a large barracks capable of accommodating two regiments of infantry, and another for cavalry on the opposite side of the river. There are here two good inns, an extensive porter brewery, a flour mill, a woollen manufactory, and a bank. About thirty years ago, this place was a miserable village, and it has been brought into its present state by John Anderson, Esq., a wealthy and public-spirited individual, to whom Ireland owes many other obligations. Land in the neighbourhood lets at from 3l to 5 guineas per acre. Distance from Dublin 107 Irish miles, and from Cork 17 miles. (J)

FERNS. See Filices.

FERNANDEZ, or JUAN FERNANDEZ, is the name of two islands in the Pacific Ocean, opposite to the western coast of South America, and about 32 leagues distant from each other. One of them, as lying farther off towards the west, is distinguished by the epithet De Afuera; and the other, as being nearer the land, is called De Tierra. It is to the latter, that the name of Juan Fernandez properly applies, an appellation which it is supposed to have received from a Spaniard of that name, who resided upon it for some time, and afterwards removed to the continent. It is situated in 33° 40' S. lat. and 79° W. Long. 110 leagues west from the coast of Chili; and about 440 to the north of Cape Horn. It is of an irregular form, and is surrounded by a very steep shore, with five leagues in length from north-east to south-east, and only two in breadth. There are three harbours and bays in the island; but two of these, one on the west and another on the east side, are very much exposed, and have only about fourteen fathoms of water. The third, which is the largest, and is called Cumberland Bay, lies on the north-east coast; but the depth of the water, which is forty or fifty fathoms within half a cable's length of the shore, the badness of the ground, which is a tenacious mud, mixed with shells and gravel, and the want of protection from the north-east winds, render the anchorage extremely dangerous. The only security, though not always sufficient, is to sail up to the farthest part of the bay, and to moor with one anchor in the water, and another on the south-west shore. At a distance, the whole island appears like one entire rock, and is for the most part very high land. In the northern quarter, the mountains are very lofty, steep, rugged, and almost inaccessible; but it slopes away towards the south point, where a remarkable islet, or large detached rock, appears about half a mile from the main land. Upon approaching the coast, very deep and romantic vallies are perceived, intersecting the most mountainous districts, shaded with different kinds of trees, and covered with the richest verdure. The air is generally mild and se-

Climate.
There is a great abundance of trees, some producing pimento, others properties of producing grain and roots in abundance; but, towards the south-west, where the country is low and flat, the soil is loose, dry, and stony. The valleys and northern sides of the mountains are covered with trees; but the piercing violence of the south winds prevents their growth on the declivities in that direction. These trees are of various sorts, but chiefly aromatic, and many of them afford excellent timber. The myrtles are said to be the largest, and to be capable of yielding planks 40 feet in length. The pines and the cabbage tree are found in some places, but none of the American fruit trees, which grow naturally in the forests. Every part of the island is covered with a sort of grass or straw, like the stalk of oats, which grows to the height of a man; and there is a great variety of esculent vegetables, especially antiscorbutics, such as purslane, water cress, wild sorrel, turnips, and Swedish radishes.

The whole coast of the island swarm with sea-wolves, and sea-lions, as the largest are sometimes called, on account of their having a mane on their necks. By the Spaniards they are commonly named Lobos de Aculeo, or oil-wolves; because of the vast quantity of fat or blubber of which their enormous body consists, makes them appear, when they move, like a skin full of oil. Vast shoals of fish also frequent the shores, particularly cod of a large size, very similar to that of Newfoundland; and the finest lobsters, often half a yard in length, may be taken in great abundance. The only quadrupeds found on the island are goats, the original breed of which had been set on shore by Juan Fernandez, and soon became so numerous, as to furnish an excellent supply of provisions to the navigators of these seas. The land and other advantages, which the island afforded for refitting, victualling, wooding, and watering, rendered it the principal resort of the Bucaneros, and other cruisers in those quarters; and, in order to deprive them of the supplies which it afforded, the Spanish government sent a number of dogs, particularly grey hounds, for the purpose of exterminating the goats. Great numbers still remain in the steep places of the mountains, where the dogs are unable to pursue them; but where they are equally inaccessible to the pirates or the privateers. It has been observed of these dogs, that they never bark till they are brought together with others of their species; when they begin to imitate them in a strange manner, as if learning a new acquisition. No venomous creatures, or beasts of prey, or any other quadruped except these goats and dogs, have been observed on the island.

On this island Alexander Selkirk resided from the year 1705 to 1709; and from his history, Daniel Defoe is understood to have composed the interesting adventures of Robinson Crusoe. In this place also, in 1741, Lord Anson recruited the health of his crew, when they were so debilitated by the scurvy, and exhausted by the storms which they had encountered, as to be scarcely able to muster strength sufficient to heave the anchor. In 1766, the Spaniards formed a settlement, and established a garrison on the island. In the year following, Captain Carteret, in the course of his voyage round the world, attempted to enter Cumberland-bay, and was surprised to find it in the possession of the Spaniards. He neither anchored, nor had any communication with the shore; but was able to observe a number of men upon the beach, a house, and four pieces of cannon near the water side, a fort upon a rising ground about 300 yards farther from the sea, faced with stone, provided with 18 or 20 embrasures, with the Spanish colours flying on the top of it. There were 20 or 30 houses of different kinds scattered around it, a number of cattle feeding on the brow of the hills, and several spots enclosed for cultivation. Since that period no accounts respecting this settlement were laid before the public, as all access to its shores was invariably denied to strangers. But in 1792, Lieutenant John Moss of the royal navy, then commanding the ship William, employed on the southern whale and seal fishery, visited the islands of Fernandez; and in his MS. the following notices were first published in the Freneh language. For 1807. He was not aware of its having been occupied by the Spaniards, and went in his boat to look for a safe anchorage and to catch fish. Upon finding the place inhabited, he landed, and applied to the governor for leave to anchor and fish. Neither of his requests was formally granted; but getting into a position where none of the guns could bear on the boat, he caught as many fish as served the whole ship's company. Several months afterwards, however, touching a second time at Juan Fernandez, he obtained from the governor, Don Juan Calvo de la Canteza, free permission to supply the wants of his crew. The town, or village, is pleasantly situated in a fine valley between two high hills. A battery of five guns is placed round the west point of the harbour, and commands the road. It is built entirely of loose stones, piled up breast high, and formed into embrasures; but on the left of the valley, on a little eminence, another battery was then constructing of masonry, which had two faces with fourteen embrasures in each, one face pointing to the anchorage, and the other flanking the village. Two small guns also have been conveyed by a serpentine path to the top of the western hill. The whole force on the island, however, according to the report of the Commandant, consisted only of six soldiers, and forty of the settlers armed and trained. There are about forty houses in the town, and several others in different parts of the island. Every house has a garden, with arbours of grape vines; and figs, cherries, plums, and almonds, appeared in a green state. There was abundance also of potatoes, cabbages, onions, thyme, and other vegetables; but none of them in perfection, as a kind of grub is said, in a great measure, to destroy the kitchen gardens. Great numbers of goats were seen on the sides of every hill. The dress of the women is of a singular description, and was stated by the governor to be the same as that of the ladies of Chili and Peru. They wear a petticoat which reaches only a little below the knee, and which is spread out by a hoop at the bottom to a great distance round them, leaving the legs entirely exposed, which are, however, covered by drawers. They wear long hair, plaited into forty or fifty small braids, hanging straight down the back. In every house that Captain Moss entered, the women presented him with mate, the infusion of the herb of Paraguay, which is sucked up through a pipe or tube, handed
from one person to another. The women were, in general, handsome, and every house swarmed with children. Thus there was a prospect of the colony increasing rapidly in population; but it was lately stated in some of the public prints, that the Spaniards had withdrawn the whole of the garrison and settlers; so that Juan Fernandez, with all its advantages, is probably again abandoned to its original uninhabited and uncultivated state.

FERNANDEZ DE AFUERA, lies in 33° 41' South Latitude, and 81° 40' West Longitude; and as both islands are situated so directly in the same latitude, strangers are apt to mistake the one for the other; but they may be easily distinguished by the obvious circumstance of the land in De Afuera being highest towards the south, while the more elevated part of De Tierra is towards the north; and at the south point also of the latter is a large rock, or islet, about half a mile from the island. Fernandez de Afuera is generally named Massafuera by the English navigators, which is probably nothing more than a corruption of the Spanish appellation Mas-afuera, which expresses its being more remote than the other from the American continent. It is a very high and mountainous, appearing at a distance like one hill or rock, and in clear weather may be seen from Fernandez de Tierra. It is of a triangular form, and about eight leagues in circumference. Its cliffs on the south end are almost perpendicular from the sea; but on the opposite side, though the land is likewise very elevated, is a fine low point stretching northward from the bottom of the cliff, and forming a perfect level, fully a mile and a half in length. In the account of Lord Anson's voyage, there is said to be no proper anchorage except on the north side, in deep water; but Commodore Byron found good anchorage on the east side towards the south point, in twenty fathoms, within two cables length of the shore. Captain Carteret also says, that he saw no part where there was no anchorage; that on the western side particularly, there is anchorage about a mile from the shore in twenty fathom, and about two miles and a half in forty fathom, with a fine black sand at the bottom; and mentions a remarkable rock with a hole in it, on the south-west point, as a good mark for anchoring on that side. Captain Moss, however, affirms that in no part is there good anchorage; that in the places where an anchor may be let go, there is foul ground; and that nothing but great distress can warrant anchoring on the coast of this island. All the navigators who have visited it, concur in their descriptions of the extreme difficulty of landing, on account of the high surf, which breaks upon large fragments of rocks all round the island, so that a boat cannot safely come within a cable's length of the shore. The only mode of landing is by swimming from the boat, and then mooring her without the rocks; and Commodore Byron, in order to protect his men from being bruised by the rocks, as well as to assist them in swimming, provided them with cork jackets. Neither is there any other way of getting off the wood and water casks, but by hauling them to the boat with ropes; and even this is sometimes found to be impracticable. When three of Captain Carteret's crew had swam ashore for the purpose of procuring water, the surf rose so high that they could not return to the boat, and were left all night in a state of complete nakedness on the island during a violent storm of rain, thunder, and lightning. In order to protect themselves from the cold, they lay upon one another, each man placing himself alternately between the other two; and next day, by travelling along the shore, and occasionally swimming around the steep points, reached with difficulty the tent of their shipmates in another part of the island. In addition to these dangers, the men, in swimming ashore, are exposed to attacks from enormous sharks of the most ravenous kind, which were observed by Byron's crew to dart into the very surf after the swimmers. The boats of Captain Moss were stayed in one of his attempts to land; and he advises the ships which go there for seals, to have a strong built boat for the purpose of anchoring behind the surf. He found only one place, which he named Enderby's Cove, where a boat could be hauled up in a small inlet on the east side; but that only when the wind is from south-west to north-north-west.

"There are many places, however," Captain Carteret observes, "where it would be very easy to make a commodious landing, by building a wharf, which it would be worth while even for a single ship to do, if she was to continue any time at the island." It affords all the requisite refreshments for voyagers, especially in the summer season; and would be a very desirable place to touch at, were the landing rendered more easy. There is plenty of fresh running water all round the island; but the east side has the most pleasant aspect, shewing numerous valleys covered with trees, rich in verdure, and abounding in flowers of the lily and violet kinds. Down every valley runs a copious stream of water, which expands in its descent among the rocks into several successive reservoirs; but the seals go far up into these valleys, and the water has a bad taste, unless taken above the places which they frequent. These animals are so numerous on this island, that they literally cover the shores; and Captain Moss's crew took 2100 of them in a few days. There are various kinds of fish also, particularly cod, halibut, coalfish, and cray fish, in such abundance that in two hours a single boat with hooks and lines might take sufficient to serve a large ship's company for two days. They are all excellent in their kind, and many of them weigh from twenty to thirty pounds. There are many goats in the place, which are not difficult to be caught, and which Byron compares to the best venison in England. Among the birds, were observed particularly various kinds of hawks, some very large, and others as small as a goldfinch; and the pintado birds were so numerous, that in one night during a gale, Carteret's people caught not less than seven hundred, which flew straight into the fire which they had kindled on shore. Among the vegetables, the mountain cabbage was particularly noticed; and the trees consisted principally of red cedar, and a hard yellow wood like box. See Byron's Voyage round the World; Carteret's Voyage round the World; Ullon's Voyage to South America, vol. ii. p. 219; and Extracts from Captain Moss's MS. first published in the Athenaum, vol. i. p. 581.

FERNANDO DE NORONIIX, is the name of an island in the Atlantic, about 60 or 80 leagues from the coast of Brazil. It is no where above two leagues in extent. Its surface is unequal and mountainous; and in the middle of the island is a mountain called Campanoria, or the Belfry, from the resemblance of its summit to a church tower. The island is, in general, very fertile, notwithstanding the reports of its sterility so industriously propagated by the Portuguese. It produces every species of grain and fruits common in hot climates; but for the want of moisture, the crops are often destroyed. Two or three years often pass without rain, and excepting in some brooks, not a drop of water is to be found in the
Island. When Ulloa visited the island, they had had no rain for two years, but violent showers came on upon the 19th of May. The inhabitants save the water in ponds resembling cisterns.

There is in the island part of the island a Portuguese town, in which reside a governor and the parish priest.

When the Portuguese had compelled the French East India Company to evacuate this island, they erected seven elegant forts, in order to defend it. Three of these defend the north harbour, two the north-west, and two the eastern part of the island, where there is a small bay fit only for barks. The forts are all built of stone, are spacious, and are well garnished and provided with large artillery. Fort Remedios alone contained 1000 men, partly regulars, sent from Fernambuco, who are relieved every six months, and partly convicts from the opposite coast of Brazil.

The principal fort, called Fort Remedios, stands on a high steep rock washed by the sea, at the foot of which is a cavern, where vast quantities of water are continually pouring in without any perceptible outlet. "In this place, dreadful eruptions of the wind are heard at short intervals, which being compressed, struggles for a vent against the torrent of the water, and by filling the whole mouth of the cave in its ascent, leaves a large vacancy after its discharge, which is done with a noise resembling that of a volcano; but neither on the opposite side of the island, nor throughout its whole circuit, is there any place or mark, which affords the least room for conjecture with regard to the other mouths of this cavern, so that it is supposed to be at a great distance from it in the sea."

There are two harbours capable of receiving ships of the greatest burden, one on the north, and another on the north-west side of the island. The first is the best, both for shelter, capacity, and the goodness of its bottom. Both the harbours are exposed to the north and west, and when these winds prevail they are both im praticable, the ships being in danger, and all communication with the shore totally precluded by the agitation and violence of the surface. Even in easterly winds it is dangerous to attempt a landing.

The harbours or roads abound in fish of five or six different species, among which are lampreys and morenas of an enormous size. Between the months of December and April, when the turtles lay their eggs, the shores of the whole island are covered with them: they then retire into the sea, and disappear.

The inhabitants of all ranks subsist chiefly upon the Farina di pari, or wood meal, obtained from the roots called Moniato, Nane, and Yuce. It is little more than saw dust, both with regard to taste and smell. The position of the island, according to solar observations, is North Lat. 3° 56' 20", and West Long. 28° 37' 45". See Ulloa's Voyage to South America, book ix. chap. iii. and Cook's Second Voyage. (w)

FEROF ISLES. See FAROE.

FERRARA, a duchy situated in the eastern part of Upper Italy, and part of the pontifical domains. This territory is nearly of a triangular shape; one side stretches 25 miles along the shores of the Adriatic on the east, another about 58 miles to the north, and the third runs about 67 miles to the west and south, where it is bounded by the duchies of Mantua, Mirandola, and Modena, as also the provinces of Bologna and Romagna; and elsewhere by the Venetian states. The surface is in general level eastward from the river Po, which is here navigable, and divides in two branches, called Po di Volano, and Po di Primaro, both flowing in to the Adriatic, and each having a harbour at its mouth. Besides these, it is fertilized by the streams Panaro, Reno, Tartaro, and numerous artificial canals. Only one of the preceding harbours belongs to Ferrara; the other is a subject of frequent controversy between it and the neighbouring territories.

This duchy contains three cities; Ferrara, the capital, which we shall afterwards describe more particularly; Commacchio, and Cento. Commacchio occupies a situation in the midst of a considerable extent of low marshy ground, called the Commacchian Marshes, defended by a high alluvial bulwark from the sea, but penetrated by a canal, at the extremity of which is Porta Magnavacca. These marshes are not less than between 70 and 80 miles in circuit, and communicate with a salt lagoon, celebrated for the quality of its fishes. Cento is surrounded by an earthen rampart and ditch. It was the place of the nativity of Guercino, a famous painter. Besides these cities, there are 18 towns with their own peculiar and exclusive jurisdiction, and 162 parochial villages. We are not acquainted with any recent census, but, 30 years ago, the total population of the Ferrarese territory amounted to 235,294 souls.

The principal products of this duchy consist in grain, fruit, and wine; abundance of flax and hemp, some silk and wool; and it is said that horses and cattle are here of the best description. But there is no conspicuous activity in carrying on agricultural operations, nor any demonstrations of commercial enterprize. In common with the other territories of an ecclesiastical government, the people are passive and languid in their undertakings. Revenues, nevertheless, arise from imports and exports; from the fisheries of Commacchio, which are very profitable; from salt-works, and other sources. There cannot be much trade in a territory of such extent, when an annual fair, in a town called Luga, is considered as a remarkable event.

Ferrara being part of the papal domain, is governed by a cardinal, who is sent to the chief city every three years as legate a latere; and there is at the same time appointed a dignified prelate, with the title of vice-legate, who rules in his absence. The detail of civil and criminal matters, is committed to the cognizance of certain judges appointed by the Pope; and there is besides a senate, or grand council of 100 persons, chosen from the nobles, merchants, and citizens, renewed every three years; from which ten persons of each order are selected, to constitute an annual magistracy. In respect to its ecclesiastical state, the duchy is divided into nine dioceses, at the head of which is an archbishop, generally a cardinal, endowed with ample revenues, and possessing a jurisdiction over 135 parishes. There are sixty monasteries of different orders, containing 1850 monks and priests; ten convents, containing about 620 nuns; and three hospitals, in which 50 boys are maintained, but it does not appear whether these are of a religious or a civil institution.

The duchy of Ferrara is said to have been recognised very aniently as an important territory. It was a sovereign and independent state under the dominion of its own dukes, of the family of Este, who began to govern in the year 1205, and subsisted several centuries. On the death of Alphonso the Second in October 1597, Pope Clement VIII. declared the duchy had devolved to the papal see, and he took possession of it in person. Along with the other Italian provinces, it became implicated in the consequences of the French revolution. It was ceded by the Roman pontiff in 1797 to the government of France, and by it constitu-
FERRARA, a city of Italy, the capital of the duchy of Ferrara, situated on the north bank of the river Po, which here divides into two branches, called Po di Volano and Po di Primaro, both flowing to the east. This city is surrounded by a fortified wall and broad ditch, which may be filled with water by means of a canal from the river. There are five gates, called the gate of St Benedict, St Paul, St George, St John the Baptist, and the gate of the Angels; and at the south-west extremity there is a regular fortress. Within the walls are some gardens, which enlarge the dimensions ascribed to the city. There are several squares, and the streets are tolerably wide and convenient. The suburbs of St Luke and St George are without the walls, on the opposite side of the river, which is crossed by bridges near two of the gates.

The principal objects in the city of Ferrara, are churches, convents, a few edifices for public purposes not ecclesiastical, and those belonging to private individuals; but of the first there is a very great superiority with regard to numbers. The metropolitan church, dedicated to St George, the tutelar saint of the city, occupies one side the Piazza di San Crispolo, the principal square. The antiquity of this edifice remounts to the year 1185, when it was completed and consecrated, and exhibits a specimen of the bad taste which pervaded the architecture of that period, intermixed with subsequent alterations. It contains many monuments, inscriptions, and statues. Among the last, are five in bronze as large as life, ornamenting an altar, representing the crucifixion, the Virgin Mary, and other sanctified persons. There are several of fine Carrara marble, of which one of the most conspicuous, and as large as life, was erected by the citizens of Ferrara, in honour of Albert their sovereign lord, in 1593, who had repaired to the Pope with a great cavalcade, and obtained two important bulls, sanctioning the erection of a university, and certain privileges regarding succession to property. Pope Urban III. having died in Ferrara in the year 1187, was interred here, and his successor Gregory VIII. elected in the church. The architecture of the tower, which was built in 1412, and consists of marble, is much celebrated.

About the year 1506, a spacious edifice, the church of St Benedict, was built by two native architecs towards the western part of the city, to which a monastery adjoining. Here are deposited the remains of the famous Italian poet Ariosto, in a marble mausoleum, executed by Nano, a Mantuan sculptor, with two inscriptions, one of which was composed by Guarini. This monument has attracted the notice of crowned heads in their visits to Italy, while the ashes of philosophers have reposed in neglected obscurity. Ariosto was a native of Ferrara, and his house is still shown as a curiosity to strangers. It bears two inscriptions, composed by himself and his natural son, a literary ecclesiastic. The former is in these words, Parum sed aptam mihi, sed nulli obnoxia, sed non nocens, sed acer dormus, certamente neither very elegant nor poetical; the latter is, Sic domus habeat deorsum viridem, which Ariosto added in Pindarion. The house was built by him, and he died there on the sixth of June 1533. In the monastery annexed to the church of St Benedict, are preserved some important archives.

A church dedicated to St Francis was founded at an early period of the Ferrarese history, and after being frequently renewed and altered, was last completed in the year 1495. This edifice is also rich in pictures and statues, and presents several beautiful sculptures of different descriptions. It is besides remarkable for an echo which father Lana, in his work Magistraturum Naturae et Artis, considers one of the most wonderful phenomena extant. The voice of a person standing in a particular position, near the main entrance, is repeated 15 or 16 times; distinctly, and afterwards more faintly, for some intervals, until totally lost. The repetitions are so numerous, however, that, to avoid confusion, only a single syllable must be expressed, in order that the echo may be heard in perfection.

The church of St Dunstane, a spacious modern edifice, with a monastery of Dominican monks connected with it, stands towards the south-west part of the city. It was founded in the year 1710, and completed in 1726, but the Dominicans had an establishment as early as 1235. Like the former, the church has many pictures; and Celio Calfagnini, a celebrated scholar of Ferrara, bequeathed a valuable library to the convent, in the 16th century.

Besides these religious edifices, there are many more in this city worthy of attention: the total number of churches and chapels amounts to 60 or 70, independent of convents for monks and nuns. The inquisition has also a tribunal here; and the archbishop a palace adjacent to the metropolitan church. It is a modern building, commenced in 1718; it has some statues, and a staircase which is much admired.

Not far from the last of these buildings stands a great square edifice, with towers at each angle, ornamented by a balustrade, which is called the castle, and is occupied by the cardinal legate. This was originally designed as a place of security, and erected by one of the lords of Ferrara, after quelling a popular tumult. A military guard is mounted here, and the grand council assembles in a large hall devoted to that purpose.

There are two foundling hospitals for male and female children, one for orphans, and a poor's house for mendicants; also different public buildings for the administration of justice, one of which, called the palace of reason, was erected in the year 1526. The theatre is a modern structure of Ionic architecture, erected in 1786, by Joseph Campana, a Ferrarese.

Pope Clement VIII. after taking possession of the duchy, resolved to build a fort, including a large portion of the city, and several churches; but the present structure, which is of a pentagonal form, was founded only in the year 1608. It is entered by a fine marble gateway, erected in 1630, and there is a colossal statue of Pope Paul V. in marble, under whose pontificate the fortress was completed. A small garrison was lately kept in it.

Ferrara is said to have been distinguished by its literati at a very ancient period, and we have already remarked that the foundation of a university was authorized in 1591. The seminary which now appears, however, is of more modern date, having either been built or altered in 1610. It is rather a plain structure with a handsome gateway, surmounted by a tower and clock, and stands towards the south part of the city.

To judge by the extent of the literary establishment, this should be a favoured place for study, but we believe that although famous of old, it has now lost much of its celebrity. The whole consists of 22 chairs embracing the principal branches of science, an anatomical theatre, a school for the fine arts, a museum of antiquities, and a botanical garden. In sculptures, cameos, coins, inscriptions, and mosaic work, the collection is
FERRO, or HIERRA, the name of the most westerly of the Canary Isles, is about 15 miles broad, and 45 in circuit. The coast is very precipitous and difficult of ascent, but the summit is level and fertile. Ferro was formerly the meridian from which the English and French reckoned their longitude. Its longitude, according to the most correct astronomical observation, is 17° 9' 45", and North Latitude 27° 47' 0". For a full account of the history and statistics of this and the other islands, see Canary Isles. (J)

FERROL is one of the best sea-port towns of Spain, in the province of Galicia. It is situated to the north-west of Corunna, and ten leagues from Cape Ortegal. Before 1752, Ferrol was merely a fishing village, but a large town, containing many elegant public buildings, has been erected on a regular plan. The school for midshipmen is a magnificent edifice. The arsenal is deemed the handsomest in the kingdom, and there is an extensive rope-walk, and a machine for hammering the copper for sheathing vessels. There are also two hospitals, one for the inhabitants, and another for the navy and army. The harbour is extremely safe, and is on all sides protected from winds. Its position is very strong, being surrounded with redoubts, mounting five cannon on each front, and four on each side, and the whole is connected with an entrenchment and a parapet which mask the interior works. All ships that go from the harbour into the sea must, for the distance of a league, file off one by one, and pass along a shore defended by forts, and which, in case of need, may be obstructed with piles, while, on the land side, it may be easily defended in the event of a disembarkation. It would be almost impossible to besiege the town regularly. Trenches could not be opened on account of the nature of the soil, and it would be equally difficult to force the entrance of the harbour, as it is lined with strong batteries, the mole itself being well provided with heavy artillery. The basin for the fleet is very large. Every ship has a separate warehouse, where all its tackle, &c. is marked and deposited. All the work in the harbour is carried on by 600 galley slaves, who compose the presidio. The approach to the coast between Corunna and Ferrol is defended by two castles, viz. that of St Philip and Palma. No expense, indeed, has been spared by the Spanish government to render Ferrol one of the most complete naval establishments in the world. There is here a military commandant, a governor, an intendent, and a numerous staff. All foreign ships are excluded from Ferrol, only coasting vessels and Spanish ships which bring articles of necessity being admitted. Sea and river fish are caught in abundance; and in the vicinity of the town there are numerous fountains of excellent water. Ferrol contains but one manufactury, which is for sail-cloth.

The town contains only one parish, and a convent of the Servite order. The population is about 6000, excepting in time of war, when it exceeds this number considerably. The position of Ferrol, according to the most accurate sidereal observations, is at West Long. 8° 15', and North Lat. 43° 29'. See Laborde's View of Spain, vol. ii. p. 441. (a)

FEU, or FEU (feudum or feodaum, Fr. fief), a word of uncertain derivation, sometimes denoted an estate held by feudal tenure, but is more properly used to denote the right resulting to the vassal from the feudal contract. In this latter acceptation it may be defined a gratuitous right to the property of lands, under the condition of fealty and military service to be performed to the superior, who grants the right, by the vassal, who obtains it. The interest which the superior retains to himself, or rather the law reserves for him, in all feudal grants, is called dominium directum, because it is the highest and most eminent right; that which the vassal acquires goes under the name of dominium utile, being subordinate to the other, and the most profitable of the two, since the vassal enjoys the whole fruits of the subject.

Although, from the nature of the feudal constitution, feuds were originally granted solely in consideration of military services, yet services of a mere civil or religious nature were early substituted in their room, at the pleasure of the superior. And in the course of time, the spirit of the original system was so far left out of view, that services of all kinds were entirely dispensed with in some feudal tenures; but, in such cases, the vassal, who is exempted from services, must be liable in the payment either of a yearly sum of money, or a quantity of grain, or something else, however inconsiderable, merely as an acknowledgment of the superior's right.

Feuds have been divided, with reference to the sources from which they flow, into feuda ligia and non ligia. A liege-feud is that granted by a sovereign, to whom the vassal owes absolute fidelity, without exception. Feudum non ligia, on the other hand, are those derived from subjects or superiors, in which a reservation is always implied with respect to the fealty or allegiance which is due to the highest or liege lord. By the written feudal usages, feuds are divided into antiqua and nova. The former are such as come by succession; the latter such as are acquired by gift, purchase, or other singular title.

Some things are considered as essential to the constitution of a feud; some are natural to it, and others only accidental. No feud can subsist without its essential characters; and, upon the least alteration made in these, the right must resolve into one of another kind. Such essential requisites are the reservation of the right of superiority, and the acknowledgment of this right.
FEUDAL, is a term used to denote that system of legal polity, in regard to tenures of land, which was generally introduced, at an early period, among the states of modern Europe.

The origin of the feudal system is involved in considerable obscurity. Some writers pretend to have discovered traces of it among the Romans; while others have attempted to deduce its origin from the usages of the ancient Germans and Gauls. But in referring to the early history of Europe, we shall be enabled to trace it, in a more natural and satisfactory manner, to the policy of those migratory German nations, who overrun the provinces of the Roman empire, and established themselves in the conquered territory. Among these, the Longobards, or Lombards, are generally believed to have laid the foundation, or, at least, to have made the earliest improvements of the modern feudal system. That tribe, having early left their original seats in the northern parts of Germany, after many migrations, seized upon upper Italy, and established the kingdom of Lombardy, about the year 568. In order to enable them to secure their conquests, they found it expedient to divide the conquered country among their chief captains, reserving the superiority to their king; and these captains, after retaining what they deemed sufficient for themselves, parcelled out the remainder among a lower rank of officers, under the condition of fidelity and military service. The policy of this system was so universally approved of in that military age, that even after the overthrow of the monarchy of the Lombards in Italy, it was adopted by Charlemagne, and eventually by most of the princes of Europe. It was introduced into England by William the Conqueror, who, with the view of keeping his English subjects under complete subjection, divided all the lands of England, with very few exceptions, into baronies, which he distributed, according to the feudal plan, among the most considerable of his Norman adventurers.

The period of its introduction into Scotland is uncertain. It must be observed, however, that the word Feudum is not to be found, either in the laws of the Lombards, or even in the constitutions of Charlemagne, in all of which beneficium is the term uniformly employed to express a feudal grant.

Feudal grants were originally precarious, being revocable at the pleasure of the grantor; but afterwards they were generally conferred for life. During this period, however, the feudal institution may be considered as in its infancy. In a short time, the son of the feudatory was permitted to succeed to his father; and the Emperor Conrad II. summoned the Salic, in order to engage his vassals more effectually to his interest, in an expedition which he undertook to Italy, in the year 1036, extended feudal succession to grandsons, and even, in the collateral line, to brothers, in the case of a feudum antiquum. This celebrated constitution paved the way for the hereditary descent of feudal tenures.

The feudal law had early received considerable improvements from the numerous constitutions, both of the Lombard kings, and of Charlemagne and his successors; yet its principles were but little known, as these constitutions were not for some time collected into one body. In order to obviate this inconvenience, the Emperor Frederick, surnamed Barbarossa, directed an institute of the feudal system and usages to be compiled, about the year 1170, which was entitled Consuetudines Feudorum, and is subjoined to Justinian's novels, in almost all the editions of the Corpus juris civilis.

This collection, in so far as it is the work of private hands, does not appear to have been expressly confirmed by the authority of any of the German emperors. But it is generally understood to have had their approbation, and was accounted the customary feudal law of all the countries subject to the empire, with a few exceptions in favour of particular usages in certain cities and districts. But the authority of those written usages has not been acknowledged by any other state; every kingdom having received the institution with particular modifications, and formed for itself such a scheme of feudal laws as best accorded with its own particular constitution. (2)

FEVER. See Medicine.

FEZ, or Fas, the capital of the ancient kingdom of that name in Western Barbary, was founded about the 183th year of the Hegira (A. D. 786,) by Idris, a descendant of Mahomet, who had fled from Medina to avoid the persecution of the Caliphs. It is situated on gently rising grounds at the bottom of a valley, watered by the river Rasalema; but the centre of the town lies very low, and in the winter season is wet and dirty, and at all times rather unhealthy. It consists of two divisions, the new town, called Fez Jedid, and the Old Fez el Bâleel. The former was founded about the end of the 13th century, when the kingdom of Fez was united with Morocco under the sovereigns of the Marin dynasty. It is a well built town, in an elevated and healthy situation, surrounded by a double wall, and contains the citadel where the governor has his residence, a large palace, a magnificent mosque, and the greater part of the machinery employed by the different trades. Its gardens are particularly delightful, abounding in all sorts of delicious fruits and odoriferous flowers. Old Fez has been highly celebrated for its ancient splendour; and is said to have contained 62 market places, 86 public fountains, 200 streets, 600 mosques, and 200 bridges over canals and branches of the river. Though now greatly reduced, it is still the most celebrated city in West Barbary; and though less extensive than the metropolis of Morocco, it is full of finer houses, and contains a greater number of inhabitants. The houses are spacious and lofty; and have flat roofs ingeniously worked in wood, and covered with terrace. There the inhabitants recline upon their carpets in summer, to enjoy the cool breeze of the evening; and a small turret, containing one or two rooms, is erected for the females of the family. The portals are supported by pillars of brick, covered with plaster; and, in the centre of each house, is an open square surrounded by a gallery, which communicates with the stair-case, and into which the doors of the different apartments open. These doors are wide and lofty, made of curiously carved
wood, painted with various colours; and the beams of the roofs are also whimsically and gaily painted in the Arabesque style. Every house is supplied with water from the river, which enters the town by covered channels; and the principal dwellings have private baths and cisterns. A bath is attached to every mosque, for religious ablutions, and there are public baths in various parts of the town to which the people resort, the men at one hour, and the women at another. There is a great number of mosques, sanctuaries, and other public buildings; and about fifty of these are very sumptuous edifices, ornamented with a kind of marble procured in the Atlas mountains, and unknown in the countries of Europe. A few professors and students are maintained in the mosques, and the rich Moors send their children thither for their education; but their studies are chiefly confined to the explanation of the Koran, and the principal advantage is the purity of the Arabic spoken in the city. The mosque, called Carubin, is one of the most ancient and magnificent edifices in the empire of Morocco, and perhaps in all Africa; but has not been found to correspond with the glowing description by Leo Africanus. There are a very few of those hospitals mentioned by early writers, where there is indeed no physicians in attendance, but where the poor are supplied with food, and the sick are attended by women. Among these is a madhouse, where the lunatics are chained down in apartments, which are disgustingly filthy, and treated in a very harsh manner. The caravanseras or inns, are very numerous, amounting nearly to 200. They are three stories high, and contain from 50 to 100 apartments, each of which is provided with a mat and a water-cock. The traveller pays so much a day for his room, but brings his own bedding, and purchases and dresses his own provisions. Each trade and article of merchandise has its separate department; and there is a large square place divided into twelve wards, which are filled chiefly with silk cloth and linen shops, provided with sixty clerks or itinerant auctioneers, who go about with the different pieces in their hands, crying, “who bids more?” and sell the lot to the highest bidder. The inhabitants of Fez rear a great deal of poultry, which they keep in cages to prevent them running about the house. No animals are permitted to be slaughtered in the city, but are killed at a distance near to the river; and, after the price has been fixed by the officer, who superintends the price of provisions, is sent to the shops in the town. There are many corn mills in the city, where the poorer sort buy the flour in small quantities, and where the richer inhabitants send their own corn to be ground. The population of the old and new towns is estimated at 380,000; and the people, though more polished than the other Moors, are remarkable for their bigotted spirit. “If a Christian,” says Jackson, “were there to exclaim, Allah k’beer, 'God is great,' he would be invited immediately to add to it, 'and Mohammed is his prophet.' which, if he were inadvertently to utter before witnesses, he would be irretrievably made a Mohammedan, and circumcised accordingly.” They were in former times still more infamous, on account of their licentious manners; and debauchery was even encouraged by the government as a source of revenue: but at present the state of morals is not worse than in the other cities of the empire.

When the Mahometans of Andalusia, Granada, and Cordova, during the revolutions in Spain, passed over to Fez, they introduced the Spanish method of dressing and dyeing sheep and goat skins, red and yellow, and called Cordovan, now Morocco leather. At Fez, also, was first established the manufacture of milled woollen caps worn by the Moors, and brought to so great perfection at Tunis. They are named Fez by the Turks, which confirms the account of their having originated in that city. Besides gauzes, silks, and other stuffs fabricated at this city, it is celebrated for an elegant manufacture, namely, sashes of silk and gold. In addition to its own manufactures, Fez is the common magazine of Barbary, to which are brought all kinds of commodities from the sea-ports of Morocco and the Mediterranean, from the eastern countries by the caravans of pilgrims, and from the centre of Africa by the caravans of merchants. Its chief exports are almonds, gums, raisins, dates, caraway seeds, and warm seeds, citron, capers, oil of olives, tallow, hides, tanned leather, particularly Morocco leather, ostrich feathers, lead ore, elephant's teeth. To Timbuctoo, the merchants of Fez send various articles of European, Indian, and Barbary produce, especially linens, muslins, fine cloths, raw silk, beads, brass nails, coffee, tea, and sugar, shawls, and sashes of silk and gold, baiks (pieces of cloth used by the Africans as outer garments) of silk, cotton, and wool; turban, spices, tobacco, and salt. In return, they receive gums, gold rings, elephant's teeth, ambergris, ostrich feathers, and slaves. The caravans, which carry on this trade from Fez to Timbuctoo across the desert, generally travel seven hours a-day at the rate of 3½ miles an hour, and complete the journey between the two cities in 129 days, 5½ only of which are employed in actual travelling.

On account of the number of Mahometan saints said to have been buried in Fez, it is considered by the Moors as a sacred asylum, and an object of devotion. Hence all Jews and Christians are prohibited from entering its gates; and an order from the emperor is necessary before they can gain admission. This, however, seems to apply only to Old Fez, for the new town is principally occupied by Jews, who, notwithstanding the contempt with which they are treated, carry on a regular trade with the inhabitants of the city. In the various revolutions to which the country of West Barbary has been subject, the citizens of Fez were always ready to change their master, and generally yielded at the first approach of a victorious leader. They pretend even to plead, that this is a privilege which they enjoy from the founder of their city; but it is considered as proceeding rather from their own cowardice, or from the situation of the place, which is incapable of defence. Old Fez is several leagues in circumference, but a great part of the enclosed space is occupied by gardens. It is about 120 miles from the sea-coast, and 36 from the city of Morocco, to which there is an excellent road along a pleasant plain, watered by numerous rivulets and canals. The communication between these two cities is very easy and expeditious, by means of mules, which may be had ready saddled at all hours of the day, and which accomplish the journey at an easy pace in six hours, so as frequently to return the same day.

In the year 1799, a dreadful plague, which spread over all the empire of Morocco, originated in this city, which some ascribed to infected merchandise from the East, and others to the pestilential smell of the dead locus which infested West Barbary during the seven preceding years. In the cities of Old and New Fez, it carried off 1200 or 1500 persons daily; and during its continuance, 65,000 of the inhabitants perished. This deadly calamity produced a wonderful alteration in the circumstances of the survivors, and reduced all
FEZ.

FEZ, a province of the empire of Morocco, is bounded on the north by the province of Errif, on the east by Telda, on the south by the mountains of Atlas, on the southwest by Shawiya, and on the west by Ghar and Benhassan. Its dependencies are very extensive, and include several mountainous tracts, well cultivated, and full of inhabitants. Its principal mountains are Zaraghe, one side of which is covered with vines, while the other is completely barren, and which lies between the river Seboo and the plain where the capital stands; and Zarkon or Zararum, which is shaded with olive trees, and on the summit of which are the ruins of Titules or Tuulti, once a considerable town, but demolished by a prince of the family of the Almoravides.

The Seboo, one of the largest rivers of West Barbary, rises in the eastern part of the province near the foot of the Atlas mountains, and passes within six miles of the city of Fez. It is impassable, except in boats and rafts; and at Mamora, where it enters the ocean, is a deep and navigable river, capable of affording a cheap conveyance for corn to the city of Fez, which is at present supplied with that essential article by means of loaded camels, whose hire often exceeds the original cost of the grain. The river Bu Regreg, also, which discharges itself into the ocean between the towns of Salé and Rabat, rises on one of the mountains of Atlas, and proceeds through the woods and valleys of the territory of Fez. The only other town in the province, of any note, besides the capital, is Mequines, which will be described in a separate article. The whole of this province is a rich champaign country, remarkably productive in grain. The soil is a rich black, sometimes reddish mould, without stones or clay. No other manure is employed, than the long stubble burned on the field; and no other culture is necessary than to throw the grain upon the ground, and cover it with the plough. The principal crops are wheat and barley; but in lands adjacent to the rivers, beans, peas, caravansaries, rice, and Indian corn, are occasionally cultivated. There are few trees, except the olive plantations and gardens around the cities of Fez and Mequines. Fruits of various kinds are very abundant, particularly oranges, (which are frequently sold at a dollar a thousand,) grapes, melons, and figs of different sorts. Cherries also are produced in this province, though they are said not to ripen in any other part of the empire. In the country around the city of Mequines, as well as in the province of Benhassan, is produced the tobacco called Mequinas, which is so much esteemed for making snuff. A mineral, salt of a red colour, exceedingly strong, is dug at Marquagua on the vicinity of Fez; and considerable quantities of salt petre are also produced in the adjoining country. Near to the city is a mineral spring, which is said to be an infallible remedy for the venereal disease, if used for forty days successively; and many persons in all stages of the disorder, resort to its waters with much advantage. On the western side of the plain of Fez, is a village containing the sanctuary of Sidi Idris, the founder and first sovereign of Fez; and this asylum, to which malefactors frequently betake themselves, is never violated by the emperor, or any other authority in his dominions. The country part of this province is inhabited altogether by Arabs, except a small tribe of Beraberas. See Jackson's 'Account of Morocco,' p. 13; and 'Modern Univ. Hist.' viii. and 'Playfair's Geography,' vol. vi. (q)

FEZ, formerly a distinct kingdom, and the first established Mahometan sovereignty in West Barbary, contained seven provinces, viz. Fez, El Garb, Errif, Beni-hassan, Temsena, Shawiya, and Telda. The first of these has been described above; and the rest will be found under the article Morocco, with which they are now united as one empire. Of that empire, in short, the kingdom of Fez forms the northern division, and is separated from it by the river Morhaya on the south. It is bounded on the east by Algiers, and on the north and west by the sea. It is inhabited chiefly by Arabs, who dwell in tents, and are divided into various tribes; but the mountainous districts of Atlas are occupied by Beraberas. The kingdom of Fez owes its origin to Sidi Idris, a descendant of Mahomet, who fled into Mauritania about the end of the eighth century, to avoid the persecuting sword of the Caliph Abd-Allah. He first settled at Tuilli, in the mountain of Zaaron, or Zerone, between Fez and Mequines, where he spread the religion of Mahomet, and acquired by his virtues such great influence among the natives, that they became desirous to live under his government, as well as to adopt his religious creed. According to some authors, it was the son of this person, named also Idris, who founded the city, and established the monarchy of Fez, which was for a long time called by the Mahometans the court or kingdom of the West. The descendants of this prince continued to reign about 150 years; but during the tenth century great divisions began to prevail, and crowds of usurpers arose in the west of Barbary. The tribe of Zenetes, called Mequinesi, seized upon several provinces, and founded the city of Mequines, within ten leagues of the capital. A marabout of that tribe, having by fanatical predictions seduced the minds of the people from the family of Idris, formed a considerable party in the province of Temsena, and marched against the king of Fez, who was thus forced to acknowledge the authority of the Zenetes at Mequines. Another of these innovators, who professed to be a descendant of Ali and Fatima, proclaimed himself El-Mohadi, or pontiff of the Mussulmans, and accused the house of Idris of following a heretical sect. He succeeded in expelling the princes of that family from their governments; and having declared himself Caliph, he marched towards Mount Atlas to extend his dominions. While he was thus engaged in the South, Al-Habed Almoros, one of the generals of the king of Cordova, arrived with an army to aid the house of Idris; and, having conquered a part of the kingdom of Fez, garrisoned the city of Azara, which was taken for some time under the government of the Moors in Spain, El-Mohadi, by this diminution of his power, and by the hatred

* One of these princes named Sharif El Idrisi, was the author of the work entitled Geographia Nubienesis, which he dedicated to Roger king of Sicily, to whom court he had fled for protection.
which he excited by his cruelties, was unable to retain his usurped authority in Fez, and was obliged to pass into the eastern part of Africa. The whole of northern Africa was, at this time, torn by divisions, in consequence of a tradition, that, 300 years after Mahomet, another director of the faithful should come from the West. Various impostors, profiting by this belief, attempted to seize the supreme power, and were successively displaced by new pretenders. About the middle of the eleventh century, Abu Tissifin, chief of the Morabithoon, or Morabites,† a tribe which originated in the neighbourhood of Tunis, traversed Mount Atlas at the head of a numerous army, and took possession of the city of Agmec. Here he fixed his residence, and extending his conquests northwards, proclaimed himself Emir El Mumemine, the chief of the faithful. His arms were constantly victorious; and, after various battles with the petty monarchs who held the different cities, he remained sovereign of Mauritania; and founded the dynasty of the Morabites, or as they are termed by the Spanish writers, the Spanish Morlern. He was succeeded in 1056 by his son Yusef, who founded or rather finished the city of Maroksh, or Morocco, which his father had begun; and there established the seat of his empire. A multitude of Zenetes, having begun to propagate new errors and innovations in the province of Temesna, he sent several Morabites to recall the people to their former tenets; but, instead of listening to their reasonings and remonstrances, the adherents of the new doctrines put them all to death, when assembled at Anaft. Enraged by this inhuman treatment of his ambassadors, Yusef passed the Morbeya with a powerful army, and ravaged the country of the offenders with fire and sword. The Zenetes, unable to oppose his progress, retreated towards Fez, demanding aid from its sovereign; but this prince, instead of affording them protection, marched against them as invaders; and coming up with them on the banks of the Buregreb, when they were harased with hunger and fatigue, he cut the greater part of them to pieces. Yusef having rendered Temesna a complete desert, returning the description to Morocco; but the deserted province, having been repopulated by colonies from the kingdom of Fez, he embraced the first opportunity of attacking the king of that country. Having entered the territories of his neighbour with a numerous army, and gained a decisive victory over his forces, he deprived him of his kingdom, and united it to the empire of Morocco, about the end of the eleventh century. See Modern Hist. vol. xvii.; Chenier's Present State of Morocco, vol. ii.; Playfair's Geography, vol. vi.; and Jackson's Account of Morocco. (q)

FEZZAN, one of the provinces of the state of Tripoli, is a considerable tract of country in the interior of Northern Africa, situated about 360 miles south of Mecutara, and nearly midway between Tunis and Egypt. It is considered as the country of the ancient Carthagines, and as corresponding with the Phazania of Pliny, (lib. v. c.5). As it is completely insalated by sandy or rocky tracts, and separated to a considerable distance from any other habitable district, it falls under the description of Oases, or fertile spots in the middle of the desert, and may be reckoned the largest Oasis that is known. It is a circular, or rather oval domain, surrounded on all sides by an irregular ridge of mountains, except on the western border, where it communicates with the flat sandy desert, or Sahara. The greatest length of the cultivated part of the kingdom is about 300 English miles from north to south, and the greatest breadth 200 miles from east to west. But the mountainous regions of Harpeth, on the eastern frontier, and other desert districts of considerable extent towards the south and west, are within its territory. On the north, it is bordered by Arab tribes, nominally dependent on Tripoli; on the east, by the hilly deserts already mentioned; on the south and south-east, by the country of the Tibbes; on the south-west, by that of the Nomadic Tuaries; and on the west by Arabs. Almost the only historical notices of this country by the ancients, are to be found in Pliny, who mentions it as one of the most important conquests of the Roman general Balbus.

The climate is at no season temperate or agreeable. Climate. The heat is intense during summer; and when the wind blows from the south, is scarcely supportable, even by the natives. A bleak north wind prevails during winter, which produces a severe and chilling degree of cold. Rain very seldom falls through the whole year, and when it does come, is little in quantity; but water, notwithstanding, is found everywhere, in wells of eight or ten feet in depth; a circumstance, supposed to be owing to the high lands by which the country is surrounded. Thunder and lightning are rare; but storms of wind, whirling up the sand and dust, are very frequent. There is not a river or stream of any note in the whole country, as far as is observed by Horneman; but Edrisi mentions a river of some size, which takes its source by Zucla, and which is lost in the sand before it reaches the sea. The soil is a deep sand, covering calcareous rock or earth, and sometimes a stratum of argillaceous substance; but, as the springs are so abundant, few regions in the north of Africa exhibit a richer vegetation. Both the soil and climate are well adapted for the growth of wheat and barley; but, from the indolence of the people, their ignorance of tillage, or the oppressions of their government, a sufficiency of corn for their subsistence is not raised in the country, and they depend upon importations from the Arab countries to the north. Pot-herbs and garden vegetables in general are plentiful, and some semur is raised in the western districts; but the natural and staple produce of Fezzan is dates. There are few horses in the country, and camels are kept only by the wealthy inhabitants; but asses are generally used for all the purposes of burden, draught, or carriage. A few horned cattle are found in the fertile districts, which are employed in drawing water from the wells, and are never slaughtered for food unless in cases of extreme necessity. The ordinary domestic animal is the goat, and a few sheep are reared in the southern parts of the kingdom. The antelope, tiger, and ostrich, are the principal wild animals, from which the natives derive any benefit; but the more noxious and loathsome creatures are sufficiently abundant; and snakes, adders, scorpions, toads, and similar vermin, are the constant inhabitants of the fields, gardens, and houses.

Fezzan is the most advantageously situated, of all the inland countries in Africa, for the purposes of commerce, as it lies in the shortest and most convenient line of communication between the Mediterranean and the centre of Africa, as well as between Western

† The name is supposed to be derived from the word Marabout, a name given to Mahomedan Saints or Monks, and applied to the followers of Tissifin, because most of his officers were priests of that description.
FEZZAN.

Africa, Egypt, and Arabia. Its trade is, of consequence, considerable; and its inhabitants are the most enterprising merchants in that quarter of the globe; but their traffic consists chiefly in foreign merchandise, and they are enriched by the carrying trade across the deserts. The capital, Mbourzouk, is the great resort of numerous caravans from Cairo, Bengasi, Gadames, Tripoli, and Soule; and the rendezvous of all the Mahomedan pilgrims from the west and south of Africa on their way to Mecca. The caravans from the south and west bring, as articles of commerce, slaves of both sexes, ostrich feathers, tiger skins, sable, and gold, partly in dust, and partly in native grains, to be manufactured into ornaments for the inhabitants of the interior. From Bornou, copper is imported in great quantities; from Cairo, silks, calicoes, clothes, and East India goods; tobacco, snuff, and Turkey ware from Bengal; paper, fire-arms, sabres, red worsted caps, and woollen cloths, from Tripoli and Gadames; and butter, oil, corn, hemp, and camels, from the Tuaries and southern Arabs.

There are no articles of manufacture produced in the country, and the natives discover no ingenuity as artisans. The only tradesmen are shoemakers and smiths; and the latter work every metal without distinction, so that the same person, who forges shoes, makes the sultan’s horse, forms rings for the princesses. The women, indeed, make a coarse woolen cloth called abb:; but so imperfect is their manufacturing skill, that the whole work is performed solely by the hand, and the woof is inserted into the warp thread by hand.

The country of Fezzan is governed by a Sultan, who reigns with unlimited authority over his subjects, but holds his dominions as tributary to the Bashaw of Tripoli. The crown is hereditary, but does not always descend from father to son. The law of succession requires, that, when a vacancy occurs, the eldest prince of the blood royal shall ascend the throne, a regulation which frequently occasions an appeal to the sword. The Sultan, by the rules of the state, must always be of the family of the Sheerefs of Waden or Zuila. The palace is situated within the fortress of the capital, and the Sultan lives there retired, without any other innates, except the eunuchs, who act as his attendants. The Harem is contiguous to the royal residence, and the females are brought to the apartment of the sovereign, who never enters their habitation. He never appears without the castle walls, except on Fridays, when he goes to the great mosque, or on other public festivals, when he is attended by his whole court. On these days of solemnity, he rides on horseback, in a plain on the outside of the town, where his courtiers exhibit their skill in equestrian exercises, or practise the art of shooting. On these days of state and ceremony, the Sultan’s apparel consists of a large white stuff frock or shirt, made in the Soule fashion, and brocaded with gold and silver. Under this covering, he wears the ordinary dress of the Tripolitans, without any thing remarkable in his appearance, except his turban, which extends a full yard from the front to the hinder part, and is not less than two thirds of a yard in breadth. His official attendants are the first and second ministers of state, both of whom must be freeborn men, but whose influence, notwithstanding their nominal rank, is very inconsiderable; the general of his forces, who may be appointed from any class at the sovereign’s pleasure; a number of black slaves, who are purchased when boys, and educated for the court according to their talents; and a few white slaves, termed Mamelukes, who are mostly Europeans, Greeks, Genoese, or the descendants of such, and who possess the principal interest and power.

Justice is administered by an officer, named the Cadi, who is at the same time the chief of the clergy, and possesses great influence with the people. His decisions are directed by the Mahommedan law, and acknowledged customs; and, in his absence, his secretary or scribe performs the office of judge. In criminal cases, however, the judgment is arbitrary, or is referred to the Sultan. The dignity of chief justice is hereditary in a certain family; but the sultan selects the individual of that race who is most qualified by his learning to fill the office, or, in other words, who can best read or write. The princes of the sultan’s family also claim a right of jurisdiction, and of imposing corporal punishments. Next to the Cadi, as head of the clergy, is the great iman.

The public revenues arise from territorial domains of the crown, from the royal gardens and forests, from salt pools and natron lakes, from duties on foreign trade, from assessments on all gardens and cultivated lands, and from arbitrary fines or requisitions. The public expenditure consists in the maintenance of the sultan, his court and household. The princes of the royal family are supported by portions of corn delivered weekly from the sultan’s stores, by the proceeds of territory appropriated to that purpose, and by occasional exactions from the people, levied by their personal authority, and by their own slaves. The Cadi, the great officers of the government, and the clergy, are maintained by the produce of date-tree woods and gardens, granted as temporary possessions to those who hold the respective offices.

The kingdom of Fezzan contains 101 towns and villages, among which there are few places of any note, and still fewer whose positions are ascertained. The principal are Mbourzouk, the capital, frequently called Fezzan, which is situated nearly in the centre of the country, is a walled town, and contains many ruins of ancient buildings, amidst its cottages of earth and stone. Zanila or Zuila, supposed to be the Cilaba of Pliny, is about 70 miles eastward of Mbourzouk, was once the capital of the kingdom, and is still a place of considerable importance in the country, as being the residence of many of the leading men, and of the relatives of the sovereign. Its environs are well watered, remarkable for fertility, full of groves of date-trees, and better cultivated than most other places. It contains many vestiges of ancient splendour, cisterns, vaulted caves, &c. which some writers consider as the remains of Roman architecture; but the ruins, which Mr Horneman observed, were entirely of Mahommedan origin. Jerma, or Yerma, unquestionably the Garana of the Romans, and the capital of the country at the time of its being subdued by their arms, is situated as far to the west as Zuila is to the east of Mbourzouk, and is full of majestic ruins, and ancient inscriptions. Temissa, about 120 miles eastward of the capital, is rather a garrison than a town, built on a hill, and surrounded by a high wall; the inhabitants of which derive their chief subsistence from the date trees, and employ themselves in keeping sheep and goats. The ruins of this place are merely dilapidated houses, built of lime-stone, and cemented with a reddish mortar. Katron, or Gatron, about 60 miles south of Mbourzouk, is remarkable only for the multitude of common fowls reared by its inhabitants, and the abundant crops of Indian corn in its neighbourhood.
FEZ

Mendir, about 60 miles south-east of the capital, is an
inconsiderable place, but the province, which bears its
name, is remarkable for the quantity of trona, a species
of fossil alkali, which floats on the surface of its
numerous lakes. Teghery, about 70 miles south-west of the
capital, is a small town, nearest to the western frontier.

To the north are Sooana, Sibka, Hum, and Waden.'

The population of Fezzan is calculated at 70,000 or
75,000 souls, all professing the Mahometan religion.
The genuine natives are described as a people of ordi-

nary stature, deep brown complexion, black short hair,
regular features, and feeble limbs. Their whole ap-
pearance and gesture is said to denote an utter want of
energy either in mind or body, which is ascribed to the
oppressive nature of their government, and to the ex-
treme poverty of their diet, which consists chiefly of
dates, and a kind of farinaceous pap, with sometimes,
though rarely, a little rice oil or fat. It is a common
periphrasis to designate a rich man, by saying that he is
one who eats bread and meat every day. But though
removedly abstemious in diet, they are greatly addic-
ted to drunkenness. Their beverage is the juice of
the date tree, called lughi, which, when fresh, is sweet
and pleasant, though apt to produce flatulence and
diarrhoea, or a liquor prepared from the dates, called
dusa, which is extremely intoxicating. Their ordinary
amusement in their evening meetings, is drinking, with
the occasional addition of a dancing girl, whose musical in-
strument is a rude kind of guitar, and whose motions
are sufficiently lascivious. The manners of the females,
in general, are unusually licentious, and they are vehe-
mently fond of amusement, especially of dancing in the
open places of the towns and villages, at all hours of
the day.

Their habitation are as wretched as their subsis-
tence. They are all extremely low, with no other apen-
ture for light than the door, and are built with stones or
bricks of a calcareous earth mixed with clay, and
dried in the sun. The walls are covered over with
white mortar, and the whole operations of building and
plastering, are performed without tools, entirely by the
hands of the labourer.

The dress of the Fezzaners consists of a shirt or frock
generally blue, made of a coarse linen or cotton cloth,
brought from Cairo, and the abbe of their own manu-
facture. The richer class wear the Tripolitan habit,
with a Soudan shirt over it of variegated pattern and
colours. The ornaments of the women consists chief-
ly in necklaces of glass beads, or pieces of agate with
a round silver plate in the front, trimmets made of silver
balls, coral and amber suspended from the tresses of
hair on the head, and rings of glass, horn, brass or
silver, to the number sometimes of nine or ten on each
arm and leg.

The principal diseases of the natives, are a fever and
ague, which is particularly dangerous to foreigners;
hemorrhoids or piles, which are supposed to be ag-
gravated by the immoderate use of red pepper; the
small-pox, in which an application of tamarinds and
onions is said to be employed with good effect to pre-
serve the eyes; and the venereal disorder, with which
the natives are said to be infected only once in the
course of their lives, and which they generally cure
without much difficulty, by the use of salts and colo-
quinta, or powerful catartics, washing the sores, at
the same time, with natron water or dissolved soda. Their
surgical art extends only to the setting of simple frac-
ture and occasional blood-letting, which is always done by
cupping, and never by venesection; and their practice
of medicine is confined almost entirely to amulets, con-
sisting of sentences from the Koran, written on a slip
of paper, which the patient wears about his neck, and
is sometimes compelled to swallow. See Playfair's
Geography, vol. vi.; Renel's Geography of Herodotus,
p. 566, 618; and Horneman's Travels in Africa,
p. 62. (q)

FIARS, is the name given in Scotland to the average
prices of different kinds of grain sold within the coun-
try for ready money. Their average prices are gene-

rally determined by the Sheriff in the end of February
or the beginning of March, from the evidence of a
number of respectable tenants or dealers in corn. The
method of striking the average varies in different coun-
tries. (m)

FICHTENBERG. See FRANCOIS.

FIELDING, Henry, the celebrated English novelist
and dramatic writer, was born at Sharpam Park,

near Glastonbury, in Somersetshire, on the 22d of
April 1707. His father, Edmund Fielding, Esq., who
was nearly related to many noble and respectable fa-
milies, served in the wars under the Duke of Marl-
borough, and eventually rose to the rank of lieutenant-
general. His mother was daughter to Judge Gould,
and aunt to Sir Henry Gould, one of the Barons of
Exequer.

Fielding received the rudiments of his education at
home, under the care of the Rev. Mr Oliver, a person
for whom he seems to have entertained a very great
regard, as he is generally thought to have designed the
character of Parson Trulliber, in Joseph Andrews, as
a portrait of this clergyman. He was afterwards re-
moved to Eton school, where he had an opportunity of
forming a very early intimacy with the first Lord Lyt-
tleton, Mr Fox, (afterwards Lord Holland), Mr Pitt,
(afterwards Earl of Chatham), Sir Charles Hanbury
Williams, and several other distinguished characters,
who ever afterwards cherished a warm regard for him.
By an assiduous application to study, and the cultivation
of strong natural talents, he is said to have also
acquired an uncommon knowledge of the Greek and
Latin classics, during his residence at that seminary of
education; and when about the 19th years of age, he
removed to the University of Leyden, where he studied
under the most celebrated civilians for about two years,
at the expiration of which period, he was compelled,
in consequence of the failure of remittances, to return

to London.

His father, General Fielding, having greatly in-
creased his family by a second marriage, found it im-
possible to afford his son an income proportionate to
the expense attending those fashionable pleasures in
which he had too great a propensity to indulge.
The vivacity of his temper, the brilliancy of his wit, and
his relish of all kinds of social enjoyment, made him
a most desirable companion in the circles of literature
and fashion; but having no disposition for economy,
and his finances being inadequate to the draughts made
upon him in this career of dissipation, he soon found
himself involved in difficulties, from which, however,
hopw to extricate himself by the exertion of his

genius. Accordingly, he commenced a writer for the
stage, in 1727, when he had just completed his 20th
year.

His first dramatic attempt was a comedy, called Love
in several Masques, which met with a very favourable
reception, although it laboured under the disadvantage
of succeeding the long and crowded run of the Pro-
Fielding. His second play, The Temple Beau, which came out in the following year, was also well received, and from this period, down to the year 1737, he continued to bring forward a number of plays and farces for the stage. But although these productions possess considerable merit, it is generally allowed that Fielding's genius did not qualify him to excel in dramatic writing. In his plays there is a good deal of humour and vivacity; considerable knowledge of life and manners, and abundant proof of an attentive observation of the humours, foibles, and affections of mankind; but they were evidently written with carelessness and haste: he disregarded the rules of dramatic decorum, despised the criticism of the stage, and obstinately refused to make any sacrifice to the feelings or taste of his audience.

The emoluments which he derived from his dramatic labours were by no means great; and his imprudent extravagance still continuing, he found himself obliged to resort to some extraordinary expedient to supply his necessities. With this view, about the year 1735, he determined to bring forward a new, but certainly rather hazardous species of public entertainment; which is particularly worthy of notice, as it eventually produced an extraordinary change in the constitution of the dramatic system. He brought together a great number of actors, and made preparations for exhibiting performances, chiefly of a political tendency, at the little theatre in the Haymarket, under the whimsical title of The Great Mogul's Company of Comedians. It is probable, that, in this singular undertaking, Fielding was actuated, in some degree, by resentment against the minister, Sir Robert Walpole, whom he had formerly flattered, but who had hitherto neglected him. The project had the charm of novelty, and succeeded, at first, so well, as to answer his most sanguine expectations. But this novelty wore off with the first season; and the design afterwards received so little encouragement, that he was forced to abandon it. The severity of the satire, however, which was contained in the pieces represented at the Haymarket theatre, called the minister extremely; and he determined, not only to put down this modern Aristophanes, but, like the Athenian government upon a similar occasion, to restrain the public theatres from becoming the scenes of statesmen at any future period. Accordingly, he laid hold of a piece, written by somebody or other, called the Golden Rump, which was full of abuse, not only against the parliament, the council, and the ministry, but even against majesty itself; and made such use of it, as occasioned the bringing into parliament a bill for the regulation of the theatre, and to explain an act made in the 12th year of the reign of Queen Anne, for reducing the laws concerning rogues, vagabonds, common players of interlude, &c. By this bill, which passed into a law, after some opposition, in the year 1737, the representation of dramatic performances was confined to Westminster and its liberties, or where the royal family should at any time reside; and the theatres were prohibited from bringing forward any play, or even prologue, epilogue, or song, without its being first inspected, and obtaining the licence of the Lord Chamberlain. This act also took from the crown the power of licensing any more theatres; and inflicted heavy penalties on those who should afterwards bring forward any performance, in defiance of the regulations of the statute.

Among the earlier publications of Fielding, may be noticed an Essay on Conversation; an essay on the Knowledge of the Characters of Men; a Journey from this World to the next, and the history of Jonathan Wild the Great; in which he displayed his natural humour and knowledge of mankind, but of which the moral tendency is, at least, questionable.

Some years after he began to write for the stage, he married Miss Craddock, a young lady from Salisbury, who possessed a great share of beauty, and a fortune of L.1500 pounds; and about the same time, he succeeded, through his mother, to an estate at Stower, in Dorsetshire, of somewhat better than L.200 per annum. With this fortune, he wisely determined to bid adieu to all the follies and dissipation, to which he had been hitherto addicted, and to retire, with his wife, to his seat in the country. But his natural disposition, and passion for society and show, unfortunately prevailed over all his prudent resolutions; and in less than three years from the period of his retirement from town, his extravagance, and total neglect of economy, reduced him to his former state of poverty, dependence and distress. His ardent temperament, however, did not suffer him to be easily discouraged. Having determined once more to exert his abilities, in endeavouring to procure a competent subsistence, he applied himself to the study of the law; and, after the usual period of probation at the Temple, being called to the bar, he made no inconsiderable figure in Westminster Hall. But the intemperance of his early life now began to affect his health so seriously, as to prevent him from bestowing the requisite attention on the duties of his laborious profession, and consequently from reaching that degree of eminence, which his talents and learning might otherwise have enabled him to attain. Amidst all the severities of pain and poverty, however, he still found resources in his genius. For some years he devoted his talents, in a great measure, to politics; he was concerned in a political periodical paper, called the Champion, which owed its principal support to his prolific pen; and he was himself the conductor of two publications—the True Patriot, and the Jacobite Journal, in which he supported the principles of the Hanoverian succession. About this period, of this misfortune to lose his wife to whom he had ever tenderly loved; and the fortitude which he had displayed in all the former distressing situations of his life, is said to have entirely deserted him upon this trying occasion. His grief, indeed, was so violent, that great apprehensions were, for a considerable period, entertained of his being ever again possessed of the ordinary powers of reason.

Hitherto the genius of Fielding had been chiefly employed upon hasty dramatic effusions, written, no doubt, with the view of supplying the exigencies of the moment; or upon miscellaneous subjects of more temporary interest. But the powers of his mind were now, fortunately, directed to a species of composition, in which he was peculiarly qualified to excel, and to which he is principally indebted for his reputation with posterity. His celebrated novels of Joseph Andrews, Tom Jones, and Amelia, produced in the maturity of his genius, may be considered as forming a sort of arena in the history of his own life, as well as in the literary history of his country; and have elevated Fielding to the first rank among the writers of fictitious narratives.

But the employment of his pen could evidently afford him only a precarious subsistence; and although he occasionally received large contributions from his friends, he is said to have been frequently reduced, by disease and the pressure of want, to the extremity of distress.
In the year 1749, however, he at length received a small pension from government; and, at the same time, his necessities obliged him to accept of the office of an acting registrar in the commission for the peace of Westminster and the county of Middlesex; an office which is generally obnoxious to the populace, and which, in those days, seldom failed to incur the imputation of venality and corruption, from which Fielding was not exempted. In discharging the duties of his office, he displayed uncommon vigilance and activity of mind. Besides suggesting many beneficial plans and regulations of police, he published several useful tracts upon subjects connected with the functions which he had to discharge. Among these are, An Address to the Grand Jury of Middlesex, which he delivered at Westminster in June 1749; A Proposal for making an effectual provision for the Poor, &c. An Inquiry into the Causes of the late increase of Robbers, &c.

The active and busy life of Fielding was now drawing towards a period. In 1753, his constitution had become so entirely shattered, in consequence of continual and severe attacks of gout and other disorders, that all remedies proved ineffectual; and, by the advice of his physicians, he at length determined to try the restorative effects of a warmer climate. In the following year, he accordingly set out for Lisbon; but in two months after his arrival at that place, death terminated his sufferings in the forty-eighth year of his age. He wrote a journal of the occurrences which happened to him during the voyage from England to Lisbon, which was published after his death. This work proves, that even in the last stage of bodily infirmity, his strong natural powers of intellect and observation had not deserted him.

Henry Fielding was tall in stature, and of a large and robust frame of body, until the vigour of his constitution had been broken by disease. He had an ardent temperamant, and lively passions. His affections were warm, sincere, and constant; and his conduct and deportment were open and manly. He possessed a vigorous understanding, a quick discernment, an inventive genius, and lively wit; and to considerable learning, he added acute powers of observation, and an extensive knowledge of men and manners. But the turbulence of his passions occasionally hurried him beyond the bounds of moderation; and in the article of worldly prudence he appears to have been remarkably deficient. Although at one time possessed of a moderate estate, he suffered it to be devoured by an extravagant hospitality; and the whole course of his life exhibits a constant struggle of genius with poverty and disease.

As an author, Fielding must be allowed to hold a very eminent rank. His dramatic pieces, indeed, although the production of no ordinary pen, are not considered as of first-rate excellence; but in the province of novel-writing, he has no superior, and few equals. Joseph Andrews and Tom Jones are esteemed among the most finished performances of this kind in any language; and are too universally known to require any more particular notice in this work.

An edition of the works of Fielding, with an essay on his life and genius, by Mr. Murphy, was published in London, in 1762, 4to. See also The Life of Henry Fielding, Esq. by William Watson, Edinburgh, 1807.

FIFESHIRE, the name of one of the maritime counties of Scotland.

1. Natural History.—The county of Fife is situated on the east coast of Scotland, between 56° 2′ and 56° 27′ of North Latitude, and between 2° and 2° 56′ of West Longitude from Greenwich. On the south it is bounded by the Firth of Forth, on the east by the German Ocean, and on the north by the Frith of Tay. Its western boundary is irregular, being indented by the county of Kinross, and united by an uneaven line with the shires of Perth and Clackmannan. Its greatest breadth, from Elie to Balmerino, is about 19 miles from south to north; and its greatest length, from Fife ness to the extremity of the parish of Saline, is about 48 miles from east to west. It contains about 52,144 square miles, or 263,593 Scotch acres.

The climate of Fife may be considered as mild, temperate. On the south side of the county, along the shores of the Forth, the air is warm, and friendly to vegetation. On the high grounds which traverse the middle of the county, the soil is damp, and the air cold. The northern parts, which are rather exposed, and destitute of shelter, have a very bleak aspect, and in these the air is sharp and penetrating.

There are no remarkable springs in the county. Springs which issue from the rocks of the coal-field between the Eden and the Forth, are frequently of the coldest kind; and in very places, as at Kinghorn, of considerable strength. In the middle district of the county, including the valley of the Eden, the springs are frequently saline, and issue either from beds of sandstone or gravel. In the northern portion of the shire, where trap-rocks abound, the springs yield water of the greatest purity. In the Inch Craig of Carnock, adjoining to the dam-dyke, there is a spring of petroleum, producing a liquid resembling ink, which drops almost constantly from the rock.

At a former period, there were numerous marshes and lakes in many parts of Fife, which the hand of industry has changed into fertile fields by means of draining. A few lakes still remain to enliven the scene, and give variety to the prospect. The Loch of Lindsor, in the parish of Abdie, is surrounded with high uneven ground, and presents a specimen of picturesque scenery seldom equalled. It is about a mile in length, abounds with pike, perch, and eel, and is much frequented by ducks, coots, and other water-fowl. Kilconquhar Loch lies on the boundary that divides the parish of Kilconquhar from Elie, is nearly of a circular form, and may be about two miles in circumference. It abounds with pike and excellent eels. In the parish of Auchterderran there are two lakes of considerable size, Lochgellie and Comilla; the former about three miles, the latter about two miles in circumference; and farther west, in the parish of Beith, we meet with Lochfitte, of an oblong figure, and of equal extent with either of the two last mentioned. To these may be added, Kinghorn Loch, in the neighbourhood of the town of Kinghorn, and the small lake at Otterston in the parish of Dalgety.

The rivers of this county (provincially termed water-ters or burns) are few in number, and inconsiderable in magnitude, owing to its peninsulated situation. The Leven (the only river which Buchanan takes any notice of) issues from the eastern side of the celebrated Loch Leven and empties itself into the Frith of Forth at Largo Bay. In its course through Fife, which extends to about twelve miles, it is joined by an inconsiderable stream called the Lothie, a little below the village of Leslie, and by the united rivulets of the Lochty and the Orr, about half a mile to the westward of Cameron-bridge. This river, the water of which is clear, the supply constant, and the stream weighty,
drives the machinery of a great number of mills, which at various periods have been erected on its banks. At its opening into Largo Bay, there is a considerable salmon fishery, and the river also abounds with fine trout, pike, and eels. The eels annually descend from Loch Leven to the sea in the night-time, during the month of September, and are taken in great quantities by nets placed in the river, which the fishers draw every two hours. The lands of Strathendy, before the Reformation, were subject to an annual tax of some thousands of eels to the Abbey of Inchcolm. The river Eden, which is formed by the confluence of several small streams, in the parish of Strathmiglo, moves slowly through a level valley, passes the town of Cupar, and unites with the German Ocean a little below the Gair Bridge to the north-east of the city of Saint Andrews. In its course eastward, which may extend to 20 miles, it is increased by a few tributary streams, and at its confluence with the sea, is joined by the Moatray, a rivulet collected among the hills on the left bank of the Tay. At the mouth of the Eden, a few salmon are yearly taken, and it abounds with fine trout, pike, and eels.

Along the south side of the Grampians there is an extensive plain, stretching south-west and north-east, and constituting the great valley of Strathmore; and along the south-side of the Ochils, which may be viewed as the outworks of the Grampians, there is a similar valley stretching by Alloa, Kinross, Strathmiglo, Kettle, and Cupar. The eastern portion of this valley, which is situated in Fifeshire, is known by the name of the How of Fife. It divides Fife into two natural divisions, a northern and a southern. The bottom of this valley is but little elevated above the level of the sea, so that a canal might very easily be formed which would unite the mouth of the Eden, or the harbour of St Andrews, with Loch Leven, and even with Strirling. Such a canal would be of incalculable advantage to the counties of Clackmannan, Kinross, Perth, and Fife; we may even include Angus, as a lateral branch by Lindores to Newburgh could easily be formed. The conveyance of those indispensable minerals, coal and lime, to districts at present but scantily supplied with either, would be greatly facilitated, as vessels could pass with certainty through this canal in so many hours, which have to wait at present several weeks before they are able to weather the exposed promontory of Fifeness. From the How of Fife, at Collesie, there is a lateral valley which runs into the Tay by Woodmill, Lindores, and Clatchart Craig, and another by Luthrie, Kilmany, and Forgyn, terminating in the extensive plain called Tents Moor. These valleys observe the general easterly direction of the ranges of the hills, and contain small eminences of regularly stratified gravel in different parts of their course, as at Collesie, Cupar, and Forgyn. We could offer some curious observations concerning the origin of these hills of gravel, were this a proper place to theorise.

The hills on the north side of this great longitudinal valley constitute the eastern base of the Ochil hills, with which they agree in direction and constitution. The prevailing rocks are red and white sandstone, amygdaloid, compact felspar, claystone, clinkstone, greenstone, basalt, trap tuff, and wacke. Limestone occurs only at one place on the farm of Parkhill, near Newburgh. These rocks belong to the old red sandstone formation of Werner. The more compact rocks of clinkstone, basalt, and felspar, form hills of considerable height, with precipitous scarpries, as Glenduckie hill, Norman's Law, and Lucklaw; while the other rocks of a less durable nature, such as amygdaloid and tuff, form rounded hills, usually covered with soil, as at Balmenlow side, Moonzie, and Forrest. The soil of this northern district, chiefly derived from the decay of the trap rocks, is remarkably fertile, and produces grain of the finest quality. Shell marl is here found in some places in great abundance, as at Rosie and Lord's Cairnie. This district affords calcaceous, carnelian, and jasper, and considerable quantities of gravel cemented by manganese have likewise been observed.

To the south of the How of Fife, the rocks are of a very different kind, and constitute a part of the great coal field of the river district of the Forth. The most important mineral of this district is coal, of which the following subspecies occur: pitch coal, slate coal, and cannell coal. Frequently all these are found in the strata cut through by the same pit; and a mixture of the two former in the same bed is very common. It was in this county where coal was first employed as fuel in Scotland, at least the earliest evidence of its use is said to be by a charter of William de Oberwull, in which he grants liberty to the Abbot and Canont of Dunfermline to open a coalpit upon his lands of Pitneyerrie. This charter is dated the day before the feast of St Ambrose in March 1291. The principal coalworks are situated in the parishes of Dunfermline, Dysart, Wemyss, and Markinch; at the same time it may be mentioned, that beds of coal occur in almost every parish in the district. Glance coal, provincially termed blind coal, is likewise a common production, and is used in the drying of malt and other grain, and in the burning of lime. Limestone in this district is very abundant, and in some places is of great purity. It is the compact limestone of mineralogists, and contains numerous petrifications of shells and corals, and in one or two places the impression of plants. At Limekilns on the Forth, the burning of lime is carried on to a greater extent than perhaps in any other county in Scotland. Ironstone is another very common production, and at one time was smelted in a furnace at Balgonie. Sandstone, or freestone as it is called, is a rock of frequent occurrence. In many places, it is of a fine grain and durable quality, and is well adapted for architectural purposes. It often contains bituminous wood. The other rocks found in the coalfield are slate clay, bituminous shale, greenstone, basalt, amygdaloid, wacke, and flint. In this district are situated several hills, among which may be mentioned the Binn, the two Lamonds, and Largo Law. In general the ground is moderately level. The soil is very various in quality, owing to the great variety of rocks from which it has originated. In the higher parts, a cold stiff clay prevails, while in the lower grounds the soil is less retentive, and more friendly to vegetation: The precious stone, known by the name of the Elie Ruby, is here found imbedded in a rock of trap-tuff. Lead and copper ores have been observed in different places, and the sulphurated ores of zinc; nay, it appears from the charters of the monastery of Dunfermline, that the hills of Fife formerly yielded gold.

The native plants of Fife are very numerous. They were, in part, described by the industrious Sibbald, and subsequent botanists have made considerable additions to his list. In the marshes of the county the botanist will find the mare's-tail, Hippuris vulgaris; the small water plantain, Alisma ranunculoides; the glaucous marsh hitchwort, Stellaria glauca; the water fig-wort, Scrophularia aquatic; the water hemlock, (provincially known from its deleterious qualities by the name of
Fifeshire. 

Fifeshire. 

*deathlin,) Cicaea virosa; and the basket osier, Salix Forbyana. The woods will furnish him with the yellow star of Bethlehem, Ornithogalum luteum;* the round-leaved winter-green, Pyrola rotundifolia; the alternate-leaved golden saxifrage, Chrysosplenium alternifolium; and the bird's-nest ophrys, Epipactis Nidus-avis. Macduff's cave at Elie will yield him the German Madwort, Asperugo procumbens; and the French sorrel of horticulturists. The hills will afford him the alpine bugle, Ajuga alpina; the alpine bistort, Polygonum bistortum; the common moonwort, Osmunda Lunaria; and the rock brakes, Pteridris crispa. Among the fields of wheat, the smooth rye brome grass, Bromus secalinus, appears, a common but unwelcome visitant.

Zoology.

The zoology of Fifeshire is no less interesting than its botany, in consequence of the great extent of sea coast. On the land the zoologist will meet with the rare Sorex fodiens in meadow ground, the Tringa alpina breeding in the Tents Moor, and the Sphinga atripes, a rare visitant of Cupar. The Tay and the Forth will furnish him with the Pleuronectus Rhombus, the Salmo erioz, and the Cyclopterus Montagui. On the shores he may pick up the following shells: Cactum (Dentalium) imperforatum and globularis, and Turbo cingulus; and if he is in search of the Crustacea and Radiata, the Pandalus Montagui, and the Ostrea aquilata will reward his exertions. 

History.

2. Civil History.—The county of Fifeshire at a former period appears to have been of great extent, and to have included the county of Kinross, and part of Clackmannan. The whole district was known by the name of Ross, or the peninsula, and hence Culross signified the lower part of the peninsula, Kircroes the head of the peninsula, and Muckross, now Fifeness, the snout of the peninsula. The last division may have obtained its name from the number of wild boars which infested that promonitory. At present the county is divided into sixty-one parishes, distributed into four presbyteries, which meet at their respective seats, St Andrews, Cupar, Kirkcaldy, and Dunfermline. These four presbyteries constitute the provincial synod of Fifeshire, which meets at Cupar and Kirkcaldy alternately, and occasionally at St Andrews and Dunfermline. The county is also divided into four districts for regulating the police, and transacting county business, which are called by the same names, and comprehend the same parishes, and the four presbyteries which we have mentioned. The proceedings of these district meetings are reported to the annual general meeting at Cupar, the head burgh of the shire.

The property of the county of Fifeshire is very much divided among the proprietors, and is held by different tenures. Generally the lands held by glebe and feu of the crown, sometimes of a subject superior, and in many instances of individual proprietors, these last occupiers being termed feuars. Another class of lands, the property of the royal burghs, is possessed by burghage holding, but is decreasing very fast, owing to the feus granted by corporations to private individuals. The valued rent of the county is £38,464, 12s. 4d. Scots, proportioned among the different districts in the following manner:

The number of freeholders at present on the roll amounts to 215. General Wemyss of Wemyss Castle is at present the knight of the shire. In Fifeshire, there are two complete districts of burghs, each of which sends a member to parliament, viz. one comprehending the burghs of Dunfermline, Kirkcaldy, Kinghorn, and Burntisland; and the other, Pittenweem, Eastertoun and Wester Anstruther, Crail, and Kirkcove. The burghs of Cupar and Andrews are united to Perth, Dundee, and Forfar; and Dunfermline and Inverkeithing to Stirling, Queensferry, and Culross. Fifeshire, therefore, has in effect a representation of two counties, and consequently nearly the eleventh part of the whole representation of Scotland. This, however, is no more than her just share, being nearly in proportion to the valuation and the amount of cess and land tax which are paid.

The population of the county in 1811, amounted to 52,061 males, 55,304 females, making a total number of 107,365 souls. At a former period, the landward districts must have contained a greater number of inhabitants than at present; as in travelling through the county, you frequently meet with rows of ash trees in the midst of cultivated fields, where formerly stood the hamlets of the peasantry. Even in the burghs on the shores of the Forth, ruinous buildings every where present themselves, intimating a former state of prosperity, to which, alas! they are now strangers. The active part of the population of Fifeshire, is engaged either in the pursuits of agriculture, manufactures, or fishing.

Four-fifths of the county are considered arable, and are at present under the management of judicious and active agriculturists. The farm-houses, which formerly were mean in their appearance, and afforded little accommodation to the tenants, are now built of substantial materials, and are both neat and convenient. The size of farms is very various, but on an average may be considered as not exceeding 120 acres. The ordinary duration of a lease is nineteen years. The rents are usually paid in money, and in some cases in the produce of the farm. The enclosures are chiefly formed with stone walls. Thorn hedges, which beautify a country, and yield shelter and warmth to the fields, are disliked by the farmer, on the supposition that they harbour vermin, by which he means small birds. But the same farmer who offers this objection, will not fail to permit forty or fifty pairs of sparrows to hatch their young under his roof in safety in spring, while he will blame the hedges for yielding them shelter in autumn. The distinction between outfield and infield is at present scarcely known in the country; and the high and crooked ridges which formerly prevailed, have been exchanged for a more rational and productive mode of tillage. Summer fallowing and green crops are universally adopted. It would be impossible, without descending to particular names, to mention the rotations of crops which are observed on the various soils which here occur, rotations dictated by experience, sometimes by example, and rarely...
by theory. The crops commonly cultivated are oats, of which there are many varieties; barley, and in the colder parts big; wheat both red and white, spring wheat seldom; rye on thin sandy soils; beans, peas, and tares; clover and ryegrass; potatoes, and turnips both common and Swedish; flax is raised in small quantities, hemp is never at present even attempted. Although there are many great trees around the mansion-houses of proprietors, there is still much ground in the county fit only for planting, which is at present, comparatively speaking, useless. On many farms, there is not as much wood as would make a gate. Farm-yard dung is the principal manure, and a straw yard is considered as one of the most valuable appendages of farm offices. Lime is universally used, and marl is employed in a few places. Even the refuse of the ironstone mines at Dysart, has been found a profitable manure to the sandy soils of that neighbourhood. It consists of several varieties of bituminous shale and slate clay, and was first applied to this useful purpose by Mr. Jameson of Dysart.

The Fifeshire breed of black cattle is esteemed profitable for feeding, and for the dairy. They weigh from forty to fifty stones, are usually of a black or brown colour, horns turned up, limbs short, and the body round. The cows give from ten to fourteen Scots pints of milk each day in summer. The breed of horses was formerly very small, and resembled the Highland garrons. But by the introduction of stallions from other parts, the Fife horses are now fit for the saddle and the draught. The native breed of sheep was the common white-faced kind, or mountain sheep, of a small size, with fine wool, which have been banished by the introduction of the black-faced, or Linton breed, with coarse wool, and of a wandering disposition; or by some of the improved cross breeds from England. The swine are principally of the Highland kind, with arched backs, and long bristles. Rabbits are protected in many places, and the annual value of their skins probably exceeds six thousand pounds. The number of pigeons in Fifeshire is very great, the pigeon cotes amounting to nearly three hundred.

As connected with the agriculture of the county, we may mention that there are four distilleries, three of which prepare whisky for the home market, and the other for the London trade. There are breweries in almost every village, which supply the inhabitants with ale; and strong ale is also compounded by some of the principal brewers. The manufacture of linen, comprehending damasks, diapers, checks, ticks, Osnaburg, and Silesias, gives employment to a great number of weavers in the different towns and villages. Salt is made in the neighbourhood of the great coal-works on the Forth. The tanning of leather is performed in several places. Soap and candle are manufactured in considerable quantities. Brick and tile are made at Cupar, Gair Bridge, Kirkcaldy, and Leven. Sulphuric acid is prepared at Burntisland. Ship-building is carried on as a trade at Burntisland, Kirkcaldy, Scotaland, and Anstruther.

In consequence of the great extent of sea-coast, we may expect a number of fishing villages, and presume that the county is well supplied with fish. The case is so in reality. A number of fishermen in the towns on the principal manures, and a straw yard is considered in the spring, sparlings, Salmo perlanus, are obtained.

The county of Fifeshire is intersected by numerous roads, and the materials for keeping them in repair are easily obtained. The more public roads, on which are erected turnpikes, are, with a few exceptions, in excellent condition; but the more private parish roads, in which the proprietors and farmers are materially interested, are in general bad, and in winter nearly impassable. This fault may be fairly charged upon the proprietors, who are too often careless about the management of the road-funds, and entrust the repairs to those interested only about gain, all the while seemingly not averse to the jolting which they often experience. There are few bridges deserving of particular notice. The Gair Bridge over the Eden, consisting of six arches, is in the first rank. It was built in the beginning of the sixteenth century, by Henry Wardlaw, Bishop of St. Andrews. On the south coast, there are several excellent harbours, of which Burntisland is the safest and most commodious. At a moderate expense a harbour might be constructed at Elic, which, from the depth of water, could be taken at all times of the tide, and would prove a safe retreat to the vessels navigating the Forth. In the Tay there are several ports to which ships resort. The principal of these are Scottsraig, Woodhaven, and Newburgh. The imports are chiefly wood, oak, bark, hides, flax, iron, tar, and groceries. The exports are principally connected with the coasting trade, and consist of coal, lime, grain, and manufactured goods. The ships belonging to the county may be estimated at twenty thousand tons. There are two custom-houses, one at Kirkcaldy, and another at Anstruther. The former has under its management all the ports between Aberdour and Largo, and the latter from Largo to St. Andrews. The trade on the Tay is under the inspection of the custom houses of Perth and Dundee.

There is a map of the county, published many years ago by Ainslie, which is now become useless, from the changes which have taken place in the situation of houses and the alteration of the direction of the roads, in consequence of the permanent features of nature, the hills and valleys, springs, and rivulets, not having been attended to. Mr. Givan at Cupar is at present executing a new map of Fifeshire, which we expect will be free from those defects, which are but too apparent in a great number of county plans. For further particulars, the reader is referred to Sibbald's History of Fife and Kinross, Svo, Cupar, 1803; and Thomson's Agriculture of Fife, Svo, Edin. 1800.

FIFTEENTH MAJOR (15th), in Music (xvi), is an interval, the double of the major eighth, or diapason, and thence often called the bishipason, the disdiapason, the replica of the octave, and the quinzieme; its ratio is \( \sqrt[3]{1224} \times 24 \times 106m \), and its common log. = 0.3979400.0868.

FIFTEENTH MINOR (15th), is the octave of the minor eighth, or the doubled minor eighth, as musicians improperly term it, instead of its replica; and it has the ratio of \( \sqrt[3]{1177} \times 23f + 102m \), and its common log. = 0.4210688.0755.

FIFTEENTH STOP on the Organ, is a range of pipes in large organs, which are each tuned a major fifteenth, or double octave above the corresponding pipes in the diapason stop. In accompanying choral parts in churches and concert-rooms, this stop is generally used in conjunction with the open and stop diapasons, the principal and the twelfth stops. (xvi)

FIFTH, in Music, is the numeral designation of an interval, consisting of 5 diatonic degrees, including the lowest and highest of these; but besides the intervals that can properly come under this denomination, a wider range has improperly been taken by various
writers, in giving the name of Fifth, usually with some prefix, to several different intervals; and mistakes there-
in can only be avoided by the musical student, by tak-
ing the complete view of them, that we have endeav-
oured to present below, in alphabetical order, (see Vol. II. p. 300.)

Being Fifth, or sometimes Redundant Fifth, of Hol-
er is an interval whose ratio is \( \frac{7}{4} = 1.75 \), and its common logarithm is \( \text{log} \) \( 1.75 = 0.24 \).

**Comma-deficient Minor Fifth (V)**, has the ratio 729
\[
\frac{27}{40} = 0.6875 = 6f + 26m, \quad \text{its log.} = 0.852427, 7167.
\]

**Comma-deficient Minor Fifth (5)**, has the ratio 729
\[
\frac{35}{40} = 0.875 = 6f + 26m, \quad \text{its log.} = 0.852427, 7167.
\]

**Double Comma-deficient Major Fifth (V)**, has the ratio 243
\[
\frac{25}{32} = 0.78125 = 6f + 23m, \quad \text{its log.} = 0.818537, 0909.
\]

**Double Comma-deficient Minor Fifth (5)**, has the ratio 243
\[
\frac{25}{32} = 0.78125 = 6f + 23m, \quad \text{its log.} = 0.818537, 0909.
\]

**Double Comma-redundant Sharp (or superfluous) Fifth** (\( \frac{\sqrt{3}}{2} \)), its ratio is 4096
\[
\frac{2^{12}}{2^{12}} = 4096 = 6f + 36m, \quad \text{its log.} = 0.811575, 0587.
\]

**Extreme Diminished Fifth** has the ratio \( \frac{11}{10} \), is \( 275 \pm 5f + 24m. \) See **Extreme Flat (minor) Fifth**.

**Extreme Flat (major) Fifth of Liston, (5V), has the ratio \( \frac{24}{25} = 3.84 \), is \( 275 \pm 5f + 24m. \) See **Minor Fifth**.

**Deficient Fifth of Chambers, Holder, &c.;** its ratio is \( \frac{27}{32} = 0.84375 = 7f + 30m. \) See **Comma-deficient Minor Fifth**.

**Deficient Fifth** of other writers, has the ratio \( \frac{729}{1024} \).
is also equal to €+$+2$III, or 11—3 III, by either of which it may be tuned. This interval has also been called by some the Diminished, and the Extreme Diminished Fifth, and it is the Minimum Fifth of all.

**Extreme Sharp (major) Fifth of Liston (V):**

The ratio is $\frac{16}{15}$, and its log. is \(\log_{10}(\frac{16}{15}) = \approx 0.069208 \times 18 + 34 = 34 \). It produces many different notes, that are not greatly different nor equidistant from each other, and the last of such notes nearly coinciding with the octave of the first; on which account, it is the interval almost exclusively used in the tuning of instruments. See *Succession of Fifth*, and *Temperament*.

**Major Fifth of Hussey,** has the ratio $\approx 399.84846 \times 1 + 8f + 34m$, and its common log. $= 0.807083, 5486$.

**Mean-tone Fifth,** has the ratio $1 + \sqrt{5} = 355.255867 \times 1 + 7f + 30m, = 355.25587 \times 1 + 30f + 7m$; its log. is $\approx 0.825274, 5692, = \sqrt{5} = 1.25$; this tempered fifth, four times repeated, has the peculiar property of producing an exact replica of the Major Fifth, and gives the only system that seems adapted to the tuning of the common organ; M. Losschman likewise uses it, with excellent effect, in tuning his patent enharmonic piano-fortes, and organs, with 24 sounds in each octave.

**Minimum Fifth of Henfling;** its ratio is $357.357 + 5f + 24m$. See *Extreme Flat (minor) Fifth*.

**Minor Fifth (5)** has the ratio $\frac{32}{31} = 31^1 \frac{1}{31}$.

**False Fifth of Chambers and Bemetsrieder;** its ratio is $321 \frac{1}{3} = 311 \frac{1}{3} \times 1 + 6f + 27m$. See *Minor Fifth*.

**False Minor Fifth,** of the common tune scale (\(\frac{3}{4}\)); its ratio is $\frac{3}{4} = 320.460258 \times 1 + 6f + 28m, = 5th + 0.0160258 \times 1 + 6f + 28m$, and its common log. $= 0.83492, 1164$.

**Flat Fifth,** of Overend, &c. (V), has a ratio $\frac{35}{34} = 311 \frac{1}{3} + 6f + 27m$. See *Minor Fifth*.

**Flat Fifth of Hussey and Webb,** has the ratio $\frac{35}{34} = 314.97096 \times 1 + 6f + 27m$, and its common log. $= 0.84509, 8401$; it is also their lesser fifth, and the sharp fourth of Holder.

**Greater Fifth of Holder,** has the ratio $\frac{40}{39} = 369 \times 1 + 7f + 52m$. See *Comma-redundant Major Fifth*.

**Imperfect Fifth of Marsh,** has the ratio $\frac{4}{3} = 322 \times 1 + 6f + 28m$. See *Minor-comma Minor Fifth*.

**Isotonic Fifth,** or Equal-Temperament Fifth, has the ratio $\frac{40}{39} = 371 \times 1 + 7f + 30m$, and its common log. $= 0.84399, 6920, = \sqrt{3}$, $= 457 \times 1 + 7f + 30m$, and the length of string answering thereto, is $0.674192$. See *Isotonic*, and Farry's *Equal Temperament*.

**Less, or Lesser Fifth of Holder;** its ratio is $\frac{4}{3} = 347 \times 1 + 7f + 30m$. See *Comma-deficient Major Fifth*.

**Lesser Fifth of Hussey and Webb.** See their *Flat Fifth*.

**Major Fifth (V),** is a concord, that is very commonly denominated the Perfect Fifth, or simply the Fifth; it has the ratio of $\frac{5}{4} = 353 \times 1 + 7f + 31m$; its common log. is $= 0.83890, 4004, = 0.83890 \times 1 + 7f + 31m$. See *Comma-redundant Major Fifth*.

**Minor-comma Excessive Fifth (V*):** its ratio is $\frac{5}{4} = 368 \times 1 + 7f + 32m$, its log. is $\approx 0.81000, 3819, = 0.601259 \times 1 + 7f + 32m$, and its common log. $= 0.83518, 3920, = \sqrt{2}$. See *Minor-comma Minor Fifth*.

**Reducant-flat Fifth (V') of some writers, has the ratio $\frac{5}{4} = 322 \times 1 + 28m$. See *Comma-redundant Minor Fifth*.

**Reducant (Major) Fifth of Liston (V):** its ratio is $\frac{5}{4} = 394 \times 1 + 8f + 34m$. See *Extreme Sharp (major) Fifth*.

**Reducant Fifth of Holder,** has the ratio $\frac{5}{3} = 371.947096 \times 1 + 7f + 32m$. See *Bearing Fifth*.

**Schisma defective Major Fifth (V*);** has the ratio $\frac{5}{3} = 357 \times 1 + 7f + 31m$; its log. is $\approx 0.83890, 4004, = 0.83890 \times 1 + 7f + 31m$. See *Comma-redundant Major Fifth*. **Reducant Fifth of Holder,** has the ratio $\frac{5}{3} = 371.947096 \times 1 + 7f + 32m$. See *Bearing Fifth*.
above the tenor c of 240 vibrations, it will beat flat
.81202 per second.

\textit{Sharp (Major) Fifth} (\textit{V}V), has the ratio \(26 = \frac{275}{274} \times 8f + 34 m\). See \textit{Extreme sharp (Major) Fifth}.

\textit{Sharp Fifth} of Holdcr, has the ratio \(23 = \frac{270}{271} \times 8f + 34 m\), and its log. \(= .083114,7376\). The respective author above named, has not only been betrayed into the admission of this unnatural ratio, but to the naming it also his Deficient less sixth, and his Redundant great third, in different parts of his Essay. 

\textit{Successive Fifth}, or the succession of fifths, implies the order in which they arise, in modulation; these, beginning towards the lowest are, according to Mr. Liston, B\#b, Fb, Cb, Gb, D♭b, A♭b, Fb, B♭, F, C, G, D, A, E, B, F♯, C♯, G♯; D♯, A♯, E♯, B♯, F♯♯, C♯♯; who, at page 24 of his Essay on \textit{Perfect Intonation}, remarks, that the six first and six last of the above, leaving a chromatic douzeave scale in the middle, are denominated \textit{extreme flat} or \textit{extreme sharp} notes; and so also are any other double flat or double sharp notes called, that may be produced by further extending this series either way. If the fifths, in the above series, are perfect, they answer to the \textit{Triple progression of the ancients.} See that article.

\textit{Superfluous (major) Fifth} of Tartini, Chladni, Marsh, &c. has the ratio \(23 = \frac{270}{271} \times 8f + 34 m\).

See \textit{Extreme sharp, (major) Fifth} (\textit{V}V). 

\textit{Superfluous Fifth} of Bemetziad; its ratio is

\[
4096 = 416 \times 8f + 36 m; \text{ see Double comma redundant sharp Fifth.}
\]

\textit{Temperaments of the Fifths}: in regular tempered douzeaves, eleven of the major fifths are each tempered by one-fourth of the temp. of the IIrd \(-2.75190652\); and the resulting, or wolf fifth, is tempered by 13.4637592 \(=\) eleven-fourths of the temp. of the IIrd; and, at the same time, eleven of its fifths are each tempered by 3.6693765 \(=\) one-third of the temp. of the Vth; and the resulting, or wolf fifth, is tempered by eleven-thirds of the temp. of the Vth \(-23.3542997 \times\); and further, whatever be the temperament of each, of eleven of the fifths, the other, or wolf-fifth, will be 13.0678234 \(=\) these eleven temperaments of the Vths.

A Mr. Liston's musical theorems and corollaries, in the \textit{Phil. Mag.} vol. xxxvi. p. 59, and 374.

\textit{Triqual Fifths}, or quints, of Earl Stanhope; there are three successive tempered fifths, that are either equal in magnitude, or that beat equally quick. See \textit{Equal Beating, and Triqual Quint.} (c)

\text{FIGS. See Carphification.}

\textit{FIGUERAS}, is a town of Spain, in the province of Catalonia, situated in a rich and cultivated plain of great extent. It has a parish church and two convents, one of Cordeliers, and another of Capuchins, an hospital, and a small garrison. The houses are not well built, but the streets are wide, and there is a square with piazzas round it. There are two tolerable inns in the town. A citadel was built on a little eminence near Figueras, in the reign of Ferdinand VI. at a great expense. It is called the castle of St. Ferdinand, and is extremely magnificent, being reckoned one of the finest fortifications in Europe. The walls, which are very thick, are of free stone; the moats are deep and wide, and the approaches are mined. The ramparts, magazine, stables, cellars, caverns, and hospital, are defended by a casemate. It has the form of an irregular pentagon, like the flaps of pointed pockets, and it stands nearly in the middle of a great plain, which it can defend on every side, serving as an entrenched camp for about 17,000 men. This place was, however, taken by the French in 1796; and in the council room of the fortress are still to be seen spots of ink, occasioned by the rage of an officer who threw his pen against the wall when he heard of the event. The walls have been whitened, but the ink is still visible. The plain on which Figueras is situated, is covered with fruit, wheat, rice, vegetables, flax and hemp. Population 4000. See Laborde's \textit{View of Spain.} (j)

\textit{FIGURE} of the \textit{EARTH}. See \textit{Astronomy.}

\textit{FILE}, a well-known steel instrument, having teeth on the surface for cutting metal, ivory, wood, &c.

When the teeth of these instruments are formed by a flat sharp-edged chisel, extending across the surface, they are properly called \textit{files}; but when the tooth is formed by a sharp-pointed tool, in the form of a triangular pyramid, they are termed \textit{rasps}. The former are used for all the metals harder than lead or tin; and the latter, for the softer metals, ivory, bone, horn, and wood.

Files are divided into two varieties, from the form of their teeth. When the teeth are a series of sharp edges, raised by the flat chisel, appearing like parallel furrows, either at right angles to the length of the file, or in an oblique direction, the files are termed \textit{single cut}. But when these teeth are crossed by a second series of similar teeth, they are said to be \textit{double cut}. The first are fitted for brass and copper, and are found to answer better when the teeth run in an oblique direction. The latter are suited for the harder metals, such as cast and wrought iron and steel. Each tooth presents a sharp angle to the substance, which penetrate the substance, while the single cut file would slip over the surface of these metals. The double cut file is less fit for filing brass and copper, since the teeth would be very liable to be clogged with the filings.

Files are called by different names, according to their various degrees of fineness. Those of extreme roughness are called \textit{rough}; the next to this is the \textit{bastard cut}; the third is the \textit{second cut}; the fourth the \textit{smooth}; and the finest of all the \textit{dead smooth}. The very heavy square files used for heavy smith-work, are sometimes a little coarser than the \textit{rough}; they are distinguished by the name of \textit{rubbers}.

Files are also distinguished for their shape, as \textit{flat}, \textit{half-round}, \textit{three-square}, \textit{four-square}, and \textit{round}. The shapes of the first are sometimes of uniform breadth and thickness files, throughout, and sometimes tapering. The cross section is a parallelogram. The \textit{half-round} is generally tapering, one side being flat, and the other rounded; the cross section is a segment of a circle, varying a little for different purposes, but seldom equal to a semicircle. The \textit{three-square} generally consists of three equal sides, mostly tapering; those which are not tapering are used for sharpening the teeth of saws. The \textit{four-square} has four equal sides, the section being a square. These files are generally thickest in the middle, as is the case with the smith's rubber. In the round file, the section is a circle, and the file generally conical.

The heavy and coarser kind of files are made from the inferior marks of blistered steel. That made from the Russian iron, known by the name of \textit{old sable}, and also called from its mark \textit{CCND}, is an excellent steel for files. Some of the Swedish irons would doubtless
FILE.

make the best file steel, but their high price would be objectionable for heavy articles.
The steel intended for files is more highly converted than for other purposes, to give the files proper hardness. It should, however, be recollected, that if the hardness is not accompanied with a certain degree of tenacity, the teeth of the file break, and do but little service.

Small files are mostly made of cast steel, which would be the best for all others, if it were not for its higher price. It is much harder than the blistered steel, and from having been in the fluid state, is entirely free from those seams and loose parts so common to blistered steel, which is not sounder than as it came from the iron forge before conversion.
The smith's rubbers are generally forged in the common smith's forge, from the converted bars, which are, for convenience, made square in the iron before they came into this country. The files of lesser size are made from bars or rods, drawn down from the blistered bars and the cast ingots, and known by the name of tilted steel.

The file maker's forge consists of large bellows, with coals as fuel. The anvil block, particularly at Sheffield, is one large stone of millstone grit. This anvil is of considerable size, set into and wedged fast in the stone. The anvil has a projection at one end, with a hole to contain a sharp-edged tool for cutting the files from the rods. It also contains a deep groove for containing dies or bosses for giving particular forms to the files.
The flat and square files are formed entirely by the hammer. One man holds the hot bar, and strikes with a small hammer. Another stands before the anvil with a two-handed hammer. The latter is generally very heavy, with a broad face for the large files. They both strike with such truth as to make the surface smooth and flat, without what is called hand-hammering. This arises from their great experience in the same kind of work. The expedition arising from the same cause is not less remarkable.

The half-round files are made in a boss fastened into the groove above-mentioned. The steel being drawn out, is laid upon the rounded recess, and hammered till it fills the die.
The three-sided files are formed similarly in a boss, the recess of which consists of two sides, with the angle downwards. The steel is first drawn out square, and then placed in the boss with an angle downwards, so that the hammer forms one side, and the boss two. The round files are formed by a swage similar to those used by common smiths, but a little conical.
The whole of the working part of the file is formed and finished with the hammer before it is cut off from the rod. The finished part is then held in tongs, and heated a second time to form the tang of the file.
The very square shoulder formed by the tang of a file, does not seem easy to form by the hammer. This is effected by first placing the file upon a sharp-edged tool, standing with its edge upwards in the anvil; a notch is now made on each side where the tang commences. It is then brought to the front edge of the anvil, and, by an acquired dexterity, the tang is drawn out without touching the shoulder with the hammer.
In order to prepare the files for cutting, they require to have the surface perfectly metallic, smooth, and as even as possible. The state, however, in which the files leave the hammer, is too hard for the dressing and cutting. The first thing to be done, therefore, after forging, is to soften the files by a process called annealing. This was formerly, and by many is still, performed by surrounding a close mass of the files with coals, keeping up the fire till the whole mass become red hot, and allowing them to cool gradually. In this process the files become softened, but the surface becomes so oxidized, that a stratum of considerable thickness peels off. This scale, however, is very hard, and is removed but with difficulty. This last is not the greatest evil attending this process; the surface of the steel lying immediately under the oxide, must have partly lost its property of steel. Indeed it is now known, that, by a similar process, steel, and even cast iron, can be converted into pure iron. It will be obvious, that, by the oxidation which takes place, the part which has to form the teeth of the file will be much impaired by the abstraction of its carbon. Hence it will forcibly strike any one, that steel, particularly in this instance, should be annealed in close vessels, to exclude the oxygen. This has been accomplished to a partial extent by some manufacturers, but still requires more minute attention. The annealing should be performed in troughs of fire-stone or fire-brick, similar to the cavities in which steel is converted, having the flame of a furnace playing on every side, and over the top. The trough should be filled with alternate strata of the files to be annealed, and coal-ashes, or the dust of the coals, formed in the forge-hearth. The upper stratum of files should be covered with a thick stratum of the dust, and lastly with a mixture of clay and sand. The heat should be kept up no longer than till the mass will become red hot, quite through. The whole must now be suffered to cool. When the files are withdrawn, instead of being scaled as in the old method, they will exhibit a metallic surface, and the substance will be much softer than by the common annealing.
It should be here observed, that the mass to be heated should not be more than one foot in thickness, as it would be so long in heating and cooling, that the metal would put on the crystalline form, under which it is too brittle to form a cutting edge.
We have before observed, that the steel requires high conversion for files. This will evidently become unnecessary with this mode of annealing. The surface of the files, which is the principal part, will become converted in an extra degree, by using more carbon in the annealing, and thus make steel, of common conversion, sufficiently hard for files.
The next process is the preparation of the surface for the teeth of the files. This, when it is done by means of filing, as practised in Lancashire, is called stripping.
At Sheffield, the surface of the file has no other preparation for cutting than by grinding. This is done by machinery, and at a trifling expense.
The great expedition with which the grinding of files is performed, and the little attention paid by the workman, who is totally unacquainted with every other department, cannot insure that evenness of surface which is of so much importance in the working of a file, and which is more successfully performed by stripping.
The grinding-stone would require constant examination to keep it sufficiently true for grinding an even surface, except some additional machinery could be employed for that purpose. This will doubtless be some time or other accomplished.
In the present state of the file manufacture, the larger files must be prepared on the present plan, and must
File.

remains imperfect for want of the surface being even. If this is not the case before the file is cut, it will, on using, be found to touch the surface to be filed only in a few points, instead of the whole of the teeth touching at once. It is in this particular that the Lancashire files have so much surpassed those made at Sheffield and Birmingham. The first are prepared solely by stripping; and, in consequence, their trade is confined to the small cast-steel files, for which they easily get a price double that of similar Sheffield files. When the manufacturers of the latter are told that it is in this particular that they are defective, it seems wonderful that they do not either adopt some process analogous to stripping, or contrive some machinery to grind them more exactly.

The stones used at present for grinding files, are of sharp gritstone, and of considerable size, for the large files, from four to five feet in diameter. They wear them down to about 30 inches, and then sell them to the fork-grinders. The grinder sits so as to lean over the stone, which turns directly from him, and presses on the file with both hands. The files are now transmitted to the cutter. The expedition and exactness with which the teeth of files are cut, is not surpassed by any mechanical art, depending it like solely upon human dexterity.

The file-cutter requires an anvil of a size great or less, proportioned to the size of his files, with a face as even and flat as possible. The hammers are from one to five or six pounds. His chisels are a little broader than the file, sharpened to an angle of about 20 degrees. The length is sufficient to be held fast between the finger and thumb, and of strength sufficient not to bend with the strokes of the hammer, the magnitude of which may be best conceived by the depth of the impression. The anvil is placed in the face of a strong wooden post, to which a wooden seat is attached, a small distance below the level of the anvil's face. The file is first laid on the bare anvil, one end projecting over the front, and the other over the back edge of the same. A leather strap now goes over each end of the file, and passes down on each side the block to the workman's feet, which, being put into the strap on each side, like a stirrup, holds the file firmly upon the anvil while it is cut. While the point of the file is cutting, the strap passes over one part of the file only, while the point rests upon the anvil, and the tang upon a prop on the other side of the strap. When one side of the file is single cut, a fine file is run slightly over the teeth, to take away the roughness, when they are to be double cut, and another set of teeth are cut, crossing the former nearly at right angles. The file is now finished on one side, and it is evident that the cut side cannot be laid upon the bare anvil to cut the other. A flat piece of an alloy of lead and tin is interposed between the toothed surface and the anvil, while the other side is cut, which completely preserves the side already cut. Similar pieces of lead and tin with angular and rounded grooves, are used for cutting three-square and half-square files.

Rasps are cut precisely in the same way, using a triangular punch instead of a flat chisel. The great art in cutting a rasp is to place every new tooth opposite to a vacancy as much as possible.

Although smooth files have many more teeth, they are not proportionate in labour; since more strokes can be made in the same time, as they are of less magnitude. In cutting a flat side, about $\frac{3}{4}$ inch broad, of the bastard cut fineness, a quick workman will make about 500 strokes, and as many teeth in one minute.

The smaller files are generally cut by women and children, who very soon acquire great dexterity.

The file-cutter, whatever may be the degree of fineness of the file, depends much more upon his feeling than his eyes. Indeed, their eyes are frequently directed to other objects while the chisel and the hammer are going at the full rate.

When one tooth is formed, the edge of the chisel and the surface of the file being both very smooth, the former is pushed up against the back of the first tooth, which can be much better felt than seen. By this succession of stroke and motion of the chisel, to feel the last tooth, the work is performed, although the eye is at a considerable distance from the work.

When the files are cut, the next process is to harden them. This is effected by heating them to redness, and quenching them in cold water. Some previous steps are taken to prevent the action of the oxygen of the atmosphere upon the file when red hot, and a peculiar manner of immersing the file in the water, which we shall more particularly dwell upon.

The preparing process has been improved within these ten years, so far as regards economy. The files were, before that time, first smeared with the residue of ale barrels, commonly called ale grounds, and then covered over with common salt in powder, which was retained merely by the adhesive nature of the ale grounds. They were now dried before the fire. The files were now taken once or twice and heated in a smith's fire, made of small coals, frequently moving the file backward and forward, in order to heat it uniformly red hot. At this period the file gives off a white vapour from the surface, which is the salt in the act of subliming. The surface appears at the same time covered with the salt in a liquid state, which, like a varnish, preserves the surface from the oxygen of the atmosphere, during the time it is red hot. The file is now held in a perpendicular position, and the immersion in the water commences at the point, slowly depressing it up to the tang, which should not be hardened. All files are dipped in a perpendicular direction. Those, however, which have a round side and a flat one, are moved also in a horizontal direction, with the round side foremost. Without this precaution, files of this shape would warp towards the round side. This arises from the flat side having been more hammered than the round side, which is formed by the concave die, and does not acquire the same density which the hammer gives.

It is common after hardening to temper most cutting instruments. Files, however, are never tempered at all by the maker. Nor are any but rough and bastard-cut files tempered by those who use them. If these were not in some cases tempered, the points of the teeth would break, and the file would do but little service.

When files are hardened, they are brushed with water and coak-dust. The surface becomes of a white-grey colour, as perfectly free from oxidation as before it was heated.

In applying the salt as above directed, a very great proportion of it is rubbed off into the fire and is lost. The consumption of salt used in this manufacture at Sheffield alone, amounted to about £1000 annually. The economy with which it is now used, has reduced this quantity to less than £300. This saving is effected by mixing ale grounds and the salt together, the
One of the great natural series of plants included with the Musci, Hepatice, Lichenos, Conferens, &c. in the Cryptogamia of Linnaeus, and Acotyleones of Jussieu. The writers on these plants have differed widely in their opinions as to the etymology of the word *filices*. Ainsworth derives *filix*, the name used by Pliny, from *filum quasi filatim incisum*; but Ainsworth was no naturalist: even the roots of these plants have no more resemblance to *filum*, "a thread," than those of other plants. It seems far more probable that the latter name is derived *afy vo* folium (*foliis*); the leaves or fronds of the European ferns being alone visible, as the stems and roots are either hid under ground, or decayed leaves, mosses, &c.

I. On the Germination of the Seeds, and Physical Economy of Ferns.

In describing the peculiarities in the structure of the embryo and manner of germinating of the seeds of these plants, it is necessary, for the sake of perspicuity, to present a general comparative view of the analogous parts of the embryo in dicotyledenous plants. For, as to the supposed monocotyledons, it will scarcely be credited, that in them naturalists have not hitherto determined with precision, to which part of the embryo the term cotyledon ought with propriety to be applied. In fact, there is every reason to conclude, that no organ whatever, strictly analogous with the true cotyledon, exists in the seeds of the hitherto supposed monocoty-

*Transactions of the Linnaean Society*, vol. ii.
The filices, or ferns, are remarkable plants that have been studied for their unique characteristics. Although their structure and development are complex, they are characterized by the presence of fronds, which are the primary organs of reproduction and photosynthesis. Each frond consists of a central stem and leaf-like structures, or pinnae, that are typically arranged in a spiral pattern. The reproductive structures of the fern, known as sorus, are located at the base of the fronds and contain spores that are dispersed by wind or water. The filices play a crucial role in many ecosystems, providing habitat for a variety of insects and other organisms. Their presence is a key indicator of the health and diversity of a given area.
A lateral bud is evolved from the bark, whose centre is produced from the radiated cellular matter of the trunk, surrounded with spiral sap-vessels; and a cone of wood is in like manner formed around it, whose base, during the first season, is gradually encircled by a layer of the contemporanous maternal wood.

During the second year, therefore, the base of the young shoot can receive no addition to its proper diameter, except where it is unencumbered by the wood of the trunk: so that at its origin, a branch resembles the summit of an inverted cone, enveloped by the circles of maternal wood.

As to the order of the development of the various parts of the stem, Malpighi supposed, that the internal circles of bark were subsequently condensed into wood; while Grew concluded, that the young wood was elaborated by the bark.

But the well-devised experiment of Duhamel demonstrated, that the bark itself, as well as the young wood, derive their origin from the gelatinous part of the sap, (the cambium,) exuding from the central and radiated cellular substance, in which new-sap-vessels are developed annually during the season. The experiment of Duhamel alluded to, consisted in removing completely the bark of a cherry-tree, from the trunk of which he afterwards observed the sap oozing, and forming a new bark, under which new circles of wood were afterwards formed.

We are aware, that the accuracy of this experiment has been lately called in question by Palisot de Beauvois, in a memoir read before the Institute of France, who observes, that when a portion of the bark of a tree is removed, and the part from which it is taken is well rubbed, so as to leave no remains either of bark or cambium, neither the young nor old wood produce any thing, but that the edges of the divided bark extending over the bare wood then produce new wood, which unquestionably is derived from the former bark.

But it does not seem that this experiment of M. de Beauvois invalidates the truth of M. Duhamel's conclusion; on the contrary, it is perfectly reconcilable with it. The efforts of nature are by no means limited to one mode of effecting her purpose. In fact, in both experiments the bark was formed from the cambium, from which the bark first, and subsequently the new wood, derive their origin; but in De Beauvois's experiment, the cambium oozed from the trunk covered with the remaining bark; whereas in Duhamel's, it necessarily excluded from the bare trunk.

It ought to be mentioned to the credit of Malpighi, that Duhamel's experiment partly confirmed the sagacity of his opinion, "Conquirituriaque in horizontalibus utriculis et medulla ipsa succus, ut futuris et proxime erupituris gemmis, et tenebris foliis Praesto sit." For it is evident that the increased diameter and elongation of these plants depend on the same cause, viz. the annual expansive motion of the sap in the lymphatic vessels and cellular substance of the stem, and the subsequent formation and condensation of both into bark and wood, assimilated probably by the proper juices of the respective plants, prepared by the leaves, and distributed through the descending vessels.

From this general view of the manner of growth and organization of the stems of dicotyledonous trees, we shall perceive how remarkably they differ in both from ferns.

The second period of the growth of these plants may be said to commence, when the seminal lobes, having attained their full size, a circular opening appears at the point of their union, in the centre of which the first frond may be perceived in that state of involucrion which is common to ferns with other kindred tribes. Even at this early period, the frond is at once distinguished from the seminal lobes. It is of a paler green colour, and with the stipes of a triangular form, in several species resembling the letter r, and, with the microscope, vessels may be seen elegantly ramiied, diverging from the central stipes in every direction; whereas, in the seminal lobes, which are cellular and of a darker green hue, no ramiied vessels can be distinguished. The temporary fibrous radiiplies of the seminal lobes, as well as themselves, now no longer of use, begin to fade, and their dark green sap being evidently absorbed for the nutrition of the young plant, from the tuberous stem of which the true root now descends exactly as in dicotyledonous plants. A second frond is soon perceived shooting from the axil of the first, and opposite to it, but with an additional lobe. In the same manner the fronds are thus evolved one after another, with a gradual addition to the fronds proper, during this period, consisting only a slight addition of diameter, without any perceptible increase of length. Another circumstance to be remarked in the economy of these plants, is, that even during the second year, the stems, at least of the native European species, frequently germinating in the crevices of our sandstone cliffs and Gothic ruins, are very far from attaining their utmost diameter. It is no doubt probable, that the slow growth of these plants must be greatly influenced by their situation and soil, as well as by the temperature of our northern climate, but ill adapted to foster the growth of plants, which only attain their full perfection in the luxuriant forests of the tropics. Were it, however, admissible, under circumstances where observations are greatly deficient, to derive the grounds of probability from analogy, it is probable, that even under circumstances the most favourable, ferns do not attain their utmost diameter during several successive seasons; and it would seem that these plants possess a singular analogy with palms, in this and other respects.

Both Kämpfer and Daubenton have remarked, that the Phoenix or date-palm, and others of this series, require several years before they acquire their utmost diameter; and that previous to this period, their stems do not begin to elongate, nor do their fronds acquire their perfect form and size. Now, in all these circumstances, they greatly resemble ferns. We know it has been frequently alleged, that certain species of ferns are stemless; an opinion countenanced by Sprengel, who observes, that "in this case the fronds issue from the tuber or root;" but having closely examined this supposed root, in the Dovellia Canariensis, Polypodium aureum, and other species asserted to be stemless, we found that they possessed the structure and all other properties of procumbent stems, detaching at intervals proper fibrous roots, and diverging branches, and like the arborescent species, producing fronds from the numerous buds at the extremity. Whether certain species, however, are altogether destitute of stems, it is impossible to determine with certainty; but such a circumstance is very improbable, and it is far more likely that such as are thus figured by Plumier and others, are plants in the second period of their growth, whose elongation had not yet commenced. It is certain, however, that the smallest of our native species possesses real, though very short stems.

These prostrate species form a singular contrast with those of the upright arboreous ferns. The **Cycas arbores**, C. *aspera*, and other erect species, rival in magnificence the most lofty of the palms; yet, in the economy of their reproduction, these humble species certainly surpass them, being much more prolific in buds.

When the stems of these plants have attained their utmost diameter, they may be said to have arrived at puberty. The third period of their growth commences.

The stem now gradually elongates, but except where it ramifies, invariably in a direction parallel with the axis of the great vascular fasciculi; and Sprengel is incorrect in supposing the buds of the tuberous stem to be involute or circinate, like those of the fronds which generate from it. These, in fact, consist of a round tuberous substance, of the same structure from the beginning as the maternal stem, extending longitudinally only.

The ridiculous fable of the old compilers of herbalists, concerning the Baromez or Tartarian sheep, was long ago shown by Linnaeus to have originated from the singular appearance of the tuber of a species of fern (*Aspidium Baromes*, Willd. *Sp. Plant.* 110) covered with the brown scales, common to many of these plants. It is certain, however, that the numerous ramifications of the prostrate stems, must necessarily prevent the growth of neighbouring plants, although they do not actually devour them like this chimerical sheep of the Tartars.

From the extreme slowness with which both ferns and palms arrive at an adult state, we may not presume that both partake of that longevity which it is well known palms possess, individuals of which are known to have existed above a century? With respect to ferns, indeed, few of which are necessary to the wants of mankind, no observations, as to this circumstance, are recorded.

In tracing the organization of the stem of these plants, the accuracy of Malpighi is again manifested; for, to this excellent observer, we owe the first notice of their general structure. In a figure of a horizontal section of the stem of a fern, he exhibits the distinct fasciculi of spiral vessels, surrounded with cellular matter, "Dispersus," he observes, "fibrosis fasciculi, et spiralius fistulis compagnatur, ambientibus hinc inde, utriculorum seribus." Of modern naturalists, Sprengel has given by far the best view of the structure of the stem of these plants, accompanied with figures highly magnified, of the central fasciculi of Malpighi. But however valuable an analysis of these parts be when thus exhibited, we have preferred an illustration of the general structure of the stem itself, as it appears when attentively examined by the naked eye, as affording a more correct outline, not only of the general structure, but of the relation of the several parts of the stem bear to each other. Sometimes, indeed, it would seem, that confusion is produced by too high a magnifying power; and the subject intended to be represented, is rather obscured than clearly delineated, a circumstance which seems well illustrated by the highly magnified view given by Desfontaines, of a transverse section of the stem of a fern, in an excellent Memoir on the organization of monocotyledonous plants. In order to have the view of the parts as distinct as possible, it is necessary to cut the stem across, at a distance from the lateral buds.

The buds from which the fronds of these plants are evolved, form part of the great central tuber from which the stem itself is produced. This tuber, in our northern climate, is found during winter, surrounded with the decayed stipites of the fronds of the preceding season, and closely invested with the woolly scales already mentioned. In examining these buds separately, we find that it is the superior part or frond only which is involute, or circinate, as it is termed; the stipete itself being extended nearly in a straight line from its origin within the stem. In the *Aspidium filix mas*, we have traced the diverging vascular fasciculi within the stem, before the external development of the fronds, and this appears evident in some species on cutting it across, when the large central fasciculi of the stem appear surrounded with the smaller ones of the stipites of former years. (Fig. 7, d.) The reason these are not perceptible in the section of the stem, represented in Fig. 8
FILICES.

Sprengel had the merit of first pointing out this circumstance; and he supposes "the vascular fasciculi contain the concentrated sap, analogous with the proper juice of other plants, which is elaborated in the thick solid tubes of ferns, from the humidity of the earth absorbed by the roots. The oxygen of the carbonated water entering the loose cellular texture, while the carbon, uniting with the hydrogen, is conveyed into the ascending spiral vessels, where it contributes to the formation of the fruit, and the brown membrane surrounding the fasciculi, prevents the admixture of the elaborated sap with the crude juice of the cellular texture.—This construction," he adds, "throws light on the peculiar origin of the seed-vessels in these plants, which takes place immediately from the ribs of the frond, or the continuation of the spiral vessels."

It is very probable, that the vascular fasciculi perform an important office in the formation of the parts of fructification in ferns; but it is equally so, that the fronds, like the leaves of other plants, contribute their part in the assimilation of the saccharine mucilage contained in the cellular substance of the stem, which would seem destined, not only to the nutrition and evolution of the infant germs invariably imbedded in it, but to the development of the fruit itself. What renders this opinion more probable, is the circumstance, that the abundance of the saccharine matter increases or diminishes with the health or weakness of the respective plants, and in the autumn after the ripening of the seeds, it is exhausted, and the cellular matter itself partly disappears, and the central part of the stipites is found hollow. However, an abundant supply is deposited in the stem for the use of the buds the following season. In short, this saccharine mucilage seems to possess a remarkable analogy with the cambium of Duhamel, from which, in other plants, both buds and seeds are apparently developed, and subsequently nourished and perfected.

Although in by far the greater number of species the buds are produced from the stem, there are many others, as *Polypodium reptans*, in which buds are evoluted from the top of the frond. Indeed in their general structure, the stipites of the fronds possess a considerable analogy with the branches of other plants; but they also combine with this the properties of leaf and fruit-stalks. There are, however, some species, as Schizaea diehoma of Smith, and S. bifida of Willdenow, whose stipites are destitute of frondose expansions.

The fronds in the whole series are generally green, except in the under surface, which is white in one *Aerostichum* and in *Cyathea dealbata*, and other species, whilst it is of a beautiful yellow in *Aerostichum sulphureum*.

The young buds, both of the stem and fronds, are often beset with scales or hairs, and sometimes this is the case with the under part of the expanded fronds. It is singular, that Hedwig should have mistaken these hairs in the infant fronds for antheridia; so very apt are men of the first talents to hunt after analogies where none can possibly exist.

If we except the magnificent palms, no plants are really more ornamental than ferns. To them, indeed, we are not attracted by the fine colour or perfume of the flower; but, even in our northern climate, there is a peculiar freshness and beauty in the bright green hue of the arched frond and elegantly divided pinnaule of the Brake and Polypond. No plants are better adapted than these to adorn the sloping bank of the clear and pelliby stream; and their beauty in such situations has not been overlooked by the fine taste of one of the first poets of our time:

Where the cowberry is the greenest,
Where the fontain glitters sheenest,
Where the lady fern grows strongest,
Where the morning dew lies longest.

The number of ramifications of the vascular fasciculi differs greatly in the numerous species. In the *D. aurum*, a single branch turns at a right angle into the pinnaule; whereas in the more complicated frond of *D. canariensis*, and others of a like form, several ramifications accompany the respective subdivisions of the frond; and towards the end of autumn, in our native species, a skeleton of the ligneous fasciculi can be dissected from the surrounding cellular matter, through the minute ramifications of the frond, almost to their apparent termination in the groups of capsules. In several species, these vessels swell at their extremity into knobs; a circumstance that gave rise to the hypothesis of Bernhardi, who supposed them to be the male organs; but, unfortunately for this hypothesis, it has since been observed by Sprengel, that the supposed organs are wanting in many species; but where they do exist, he admits that the minute vernal bodies contained within them are probably receptacles of the concentrated juices of the veins, which, according to his own hypothesis, performs the chief part in the process of fecundation.

Other parts in the frond have, however, by various writers, been supposed to perform this important function. Micheli, whose accuracy in other respects is well known, attributed the office of antherie to the capillary productions, which he discovered on the unevolved fronds; and, as already observed, Hedwig adopted and illustrated this opinion. (Theoria Gen. Pl. Crypt. tab. v. vii.) Gleichen considered these organs to be situated in those minute fissures, on the lower surface of the cuticle of the frond, which are well illustrated by Sprengel (T. ii. fig. 14.) in his work on cryptogamous plants; whilst Körleuter assigned this office to that production of the cuticle of the frond, which, in most of the tribes of ferns, forms the involucrem of the groups of capsules. But leaving these various hypotheses to their natural fate, it is full time to proceed to the consideration of the capsules themselves.

The singular aspect of these plants, which every one observed to spring up in wild and uncultivated places, without any visible seeds, seems to have given rise, in an age of general ignorance, to those superstitious fancies formerly prevalent in several parts of Europe. It was a practice among the people to collect the capsules, which they considered as the seeds of ferns, on midsummer eve, and make use of them in various charms. "We have the receipt of fern seed," says Godhill, in Shakespeare's Henry IV. "We walk invisible." In fact, the botanists of the sixteenth century partook in the faith of the times. Valerius Cordus, in his comment-
ries on Dioscorides, Tragus, and Baptista Porta, ignorant of the existence of the capsules, all agreed, that the powder found on the lower part of the frond produced plants. Cordus, however, contended, like one of the present time, that this powder could not be true seed, because the plants were destitute of flowers; and although Morison long afterward (Hist. Pl. P. iii. sect. xiv. p. 593.) observed and described the germinating plants of the Osmunda regalis, it is clear that he was unacquainted with the seeds being contained in capsules. It is singular, that Malpighi (Anat. Plant. p. 72. tab. 51) Grew, (Anat. of Plant. tab. 62) and Swammerdam, (Bibl. Nat.) should have discovered the true nature of the fruit nearly at the same period.

These capsules have been traced by Sprengel and Bernhardi, from their first development in the young succulent frond. They appear, when young, mixed with filaments, which at first these eminent naturalists imagined to be the male organs; an opinion which the genuine candour of Sprengel speedily relinquished for that already stated, viz. that the impregnation is effected by the concentrated proper juice contained in the ascending vessels of the fasciculi. We have already stated, that we cannot consider this process of fecundation to be effected solely by these vessels;—why should we attempt to limit, by imaginary analogies, the operations of nature? Bernard de Jussieu long ago (Mem. de l'Acad. des Sciences, 1740) demonstrated the male organs of the Marsiliaceae (a tribe possessing evident affinity with the ferns,) within their capsules. Now, although such organs have not hitherto been detected within the capsules of ferns, there seems nothing really absurd in conceiving seeds to be formed within these capsules, and perfected by the absorption not merely of the ascending sap from the vascular fasciculi of the stem and frond, but from veins returning the sap elaborated in the reticular substance of the expanded fronds. That the sap thus returns from the fronds is highly probable, from the green colour of the saccarinace mucilage, a superabundance of which, we have already observed, is annually deposited for the development and nutrition of future fronds in the stem itself.

Plate CCLIV. Fig. 9. represents a pinnule of Athyrium thelyperis, as delineated by Schmidel, in order to show the elegant ramifications of the vascular fasciculi, in contact with which the groups of capsules appear, covered with their respective involucrum. Fig. 10. a highly magnified view of one of these, with the yellow globular bodies, imagined by Bernhardi to be male organs. Fig. 11, a capsule with its ring, beginning to burst and eject the seeds.

These figures, then, although representing the fruit of the Agapetaceae only, we shall refer to as types of the respective fruit of the whole series of ferns.

The groups of capsules are termed sori, from sors, loculus. In many genera, these groups are covered with an involucrum, as represented in the Figure; but in others they are quite naked. This involucrum is evidently a production of the cuticle, and, in its early state, is organised exactly in the same manner.

GENERAL ARRANGEMENT OF FERNS.

Previous to the excellent paper of Dr now Sir James Edward Smith, published in the fifth volume of the Memoirs of the Academy of Sciences at Turin, our knowledge of the genera was very imperfect; but this celebrated botanist, by a more accurate examination of the species, was enabled to recapitulate the genera, and to reduce them, from a state of comparative confusion, nearly to their present form. Since the work of Smith, others have followed on the same principle; and Bernhardi, Swartz, and Sprengel, have respectively contributed to our stock of knowledge of these plants.

The general principles on which the genera are at present distinguished, consist in the form, attachment, and manner of opening of the involucrum; and when this envelope is wanting, in the manner in which the sori (groups) are arranged on the receptacle of the frond. To the receptacle, the capsules are generally attached by a fruit-stalk, in some so short, as to cause them appear sessile; in others of a considerable length, and sometimes branched with a capsule on each division. The receptacle, whether situated on the plane of the frond, or elevated above it, is in by far the greater number of known genera common to a numerous group of capsules, although, as will soon appear, there are instances of single multicellular seed-vessels apparently sessile in the frond itself. The capsules in most of the tribes are girt with a ring, which, on the maturity of the seeds, breaks, and springing backwards, ejects them with considerable force to some distance from the plant. This circumstance may be observed occasionally, by placing the ripened groups under the microscope, with a sheet of writing paper under them to receive the exploded seeds. In a great part of the series, many of the genera want the rings; but, instead of them, their capsules are more or less marked with strie, in the direction of which they burst.

An attempt is here made to arrange the genera on the principle of the natural method, as far as our limited knowledge of the structure of their most essential organs would admit. It is no doubt very likely, that several of those we have ventured to approximate, will be found deficient in affinity by subsequent observers; but as an adherence to truth and nature is the great object, this will only add to our satisfaction; conscious, as the illustrious Jussieu observes, that such errors originate “Non legum naturalium, sed prave eorum interpretationem, vitio.”

I. DANÆACEÆ. (PLATE CCLIV. Fig. 12. a.)
(Poropterides. Wild. Sp. Plant.)

We have commenced with this singular tribe, because although it differs most remarkably from the rest of the series, it is still more nearly related to them than the Marsiliaceæ, Lycopodiaceæ, and Gonophytaceæ, of which an account will be afterwards given in the proper place. The single multicellular seed-vessels, in this tribe nearly sessile in the substance of the frond, and which, in the genus Marattia, are endowed with a divisible septum, render it necessary to arrange them in a natural method, distinct from the other known tribes of ferns. Indeed, their solitary seed-vessels possess neither an involucrum nor ring, yet their fronds are entirely those of ferns. They possess a similar structure. They are involucrate, or circinate as it is termed, in their venation, and affect a similar pinnate form; but in their fruit they aresingularly distinct: for instead of the groups of minute capsules, as in the greater part of the series, this tribe is furnished with multicellular seed-vessels imbedded in the substance of the frond itself, and opening, when ripe, in pores on the surface, leading to the respective loculiments.

Genera.

Seed-vessels oval, distant, with a divisible or double...
septum, and a row of cells, opening on each side, in transverse, linear, or ovate pores.

The cells of the seed-vessel are arranged on each side of the double septum to the number of five or six. Of this singular genus there are four species known, two of which are described by the indefatigable Swartz, natives of the West Indies. These two species are figured by Smith, viz. M. alata and M. glauca. The other two are natives of Ile de Bourbon; the M. freaxinæ, also figured by Smith, (Icones ineditæ, tab. 46, 47, 48), and the fourth species (M. arbutifolia) has alternate, instead of opposite pinnae of the fronds. We are indebted to Swartz for an excellent figure of the generic character. (Flor. Ind. Occident. iii. tab. 29.)

(2.) Danaea. (Sm. Act. Taur.)

Seed-vessels narrow, linear, transverse, parallel to each other, imbedded in the substance of the frond. Cells in a double row, opening in pores.

Linnaeus referred the only species known to him to Asplenium, the oblong single-seed vessels somewhat resembling the groups of capsules in that genus, when supinely observed. There is a good figure of the generic character in the Annals of Botany, ii. Pl. 10.

Three species are described by Willdenow, all natives of America, viz. the D. simplicifolia, (Rudge, Pl. Gujan. tab. 36.) D. nota, (Plum. Pl. American. tab. 6.) and D. alata, (Plum. Fil. tab. 160.)

II. GLEICHENIACEÆ.

The genera of this tribe approach much nearer to the majority of the series than the last. The seeds are contained in minute capsules arranged in groups, and are unilocular, striated, and sessile. The style is transverse or oblique, and the capsules burst longitudinally in the direction of the style. The groups are naked, and, except in Mertensia, have a very limited number of capsules.

Genera.

(1.) Angiopteris. (Willd. 1814.)

Capsules elliptical, disposed in groups of five or seven, in double rows, along the secondary veins of the frond, and opening longitudinally.

There is but one solitary species, the A. excisa, hitherto known, figured by Hoffmann, (Comm. Geol. p. 29, tab. 5.) This species was brought from the islands of the South Sea by Forster; and Swartz has represented the generic character in the Annals of Botany, Pl. 10, fig. 4. This species is five feet in height, and has the aspect of a small palm.

(2.) Gleichenia. (Sm. Act. Taur. 5. p. 419. T. 9. Fig. 10. Willd. Sp. Pl. 5. 1815.)

Capsules disposed in point-like groups of three or four together.

In this genus, the lobes of the frond are rolled backward; and the Gl. polygodoides was ranked by Linnaeus under Onoclea, without regard to the want of a ring. Gl. polygodoides is a native of the Cape of Good Hope, and with two others, viz. Gl. circinata, and Gl. glauca, is described by Willdenow and Swartz. To these Brown has added six more new species, none of which are yet figured. (Prodr. Nov. Holl. p. 160.) The Gl. hemanni is the Mertensia dichotoma of Swartz, and Dicranotepis of Bernhardi. In Gleichenia the fronds are dichotomous.

(3.) Platyzoma. (Brown, Prodr. Nov. Holl.)

Capsules sessile, mixed with powder, and in distinct point-like groups.

Mr Brown observes, that this genus is scarcely distinct from Gleichenia in fructification, but it differs in having the stipes simple.

Groups or sori round; the capsules numerous, semi-bivalve.

This genus was formerly, like many others, confounded with Polypodium. The species are all natives of tropical climates, and fully described by Willdenow and Swartz; and several of the species are figured in the Act. Holn. tab. 4 and 5. He enumerates eleven species, including the Gl. Herrmanni, under the name of M. dichotoma. Two species were discovered by Humboldt in the arid territory of New Andalusia, namely, M. glaucens and M. pubescens.

III. OSMUNDACEÆ. (Plate CCLI. Fig. 19.)

In this tribe the capsules are very numerous, and, except in Osmunda, sessile, elegantly striated, generally in the form of rays on the top, and being peltate, they appear finely veined when examined by the microscope. Like the Gleicheniaceae, their capsules burst longitudinally. They have not dichotomous fronds like most of the genera of that tribe.

Genera.

(1.) Todea. (Willd. 1847.)

Capsules globular, semi-bivalve, on the transverse veins of the frond.

There is but one species only, the T. Africana, described and figured by Willdenow, (Act. Acad. Erfurt. tab. 3.) and by Plukenet, (Alm. tab. 181, fig. 5.) This is the Osmunda barbara, (Thunb. Prodr.) but, according to Brown, Todea ought not to be considered as a genus distinct from Osmunda, as it possesses pedicillated capsules.

(2.) Mohria. (Willd. 1818.)

Capsules somewhat round, dispersed, opening in an oblong pore at the side, the crenulated margin of the lobes bent in upon them.

There is but one species, the Thurifraga, as yet known. (Vid. Swartz Synops. tab. 5.) Osmunda marginalis, Lamark, Encycl. iv. p. 612. Osmunda thurifraga, Bory. Itinér. 1. p. 348.

Capsules sessile, ovate, inserted by the middle in double ranked spikelets, issuing from the margin of a pinna or frond, covered with a scale, and opening longitudinally.

For a fine figure of this singular genus, we are indebted to Sprengel, (Crypt. Plate V. fig. 39.) Linnaeus confounded it with Ophioglossum, with which it certainly has no affinity whatever.

To the accuracy of Brown we are indebted for the first notice of the singular insertion of the capsules into the receptacle. The most correct character of the genus is given by Brown and Swartz, which is here preferred to that of Willdenow, (Sp. Pl. 577,) wherein he describes fifteen species, among which the fourth, Hydroglossum hastatum, is the Lyceum of Swartz. This beautiful fern (figured by Brown, tab. 96; Pelt. Gaz. tab. 64; and Morison, sect. 14, tab. 3,) is a native of Brazil. It is distinct from the Hyel. severum, of which it was supposed to be only a variety. The stem is round and sarmentous, the frond tripinate, the last of the pinnae serrate, and the extreme lobe much extended. The whole plant is covered with woolly
Capules oval, in two ranks, on the back of narrow appendages of the summit of the frond, opening laterally in an oblong pore.

Linnaeus arranged this genus with *Acerostichum*, but it was justly separated from that genus by Smith. He gave it the name of *Schizaea*, from the gashed appearance of the fronds and their appendages. The radiate striae of the capules manifest its close affinity to the rest of the *Osmundacaeae*. Willdenow describes eight species, to which Brown has already added a ninth, Sch. rupestris. There are certain species, particularly Sch. pectinata, with a simple linear stipes, without the frondose expansion, which have an appearance singularly distinct from the generality of the species. Pluekenet (*Atmaq.*, p. 200, tab. 95.) accounted this a *j anus*, and he terms it *Juncus elegantissimus capitulis pectinatis*. In this he was followed by Hay and Morison. The other species, however, may be considered as only approaching to this uncommon form. From the capules being in some degree concealed by the inflected margin of the appendages, others of the genus, as the *Sch. elegans*, might be confounded with *Oxoea*; but the absence of rings, at once, on proper examination, shows their true character.

Capules top-shaped, opening on one side, and arranged in spikes. Of this genus Willdenow reckons seventeen species. It is very probable, however, that, on a more close examination, it will be found necessary to consider the four last as a distinct genus, their fruit-stalk, like those of *Botrychium*, rising from the ground; although, without the dissection of living specimens, it is impossible to ascertain this. The remaining fourteen species, several of which are correctly figured by Plumier and Petiver, are at once distinguished from these by their fruit-stalks, generally two, branching from the stipes, at the commencement of the frond; and, by this remarkable structure, as well as their sessile capules, the whole are clearly distinguished from *Osmunda*, with which all of them were formerly confounded. In general, they are natives of South America. The *A. villosa* (Willd. *Sp. Pl.* 5. p. 92.) which was lately discovered by Humboldt and Bonpland in South America, is a species quite distinct from *Osmunda villosa*.

(6.) *Osmunda*, (Willd. 1852.)

Capules with footstalk, globular, semilimbate, opening at the stripe, and either situated on the back of the unaltered frond, or around it, when contracted into the form of a panicle.

Willdenow enumerates only seven species; but Brown, whose accuracy is unquestionable, thinks that *Osmunda barbara*, separated from this genus by Willdenow under the name of *Tolea* (Willd. p. 76.), ought to be restored to it, on account of its pedicellate capules; so that there are eight species known, of which one, the *O. regalis*, only is a native of the moist woods of Europe. The germination of the young plants of the last species was observed by Morison, and, from his very concise and imperfect description, it would seem probable, that in this process it resembles those whose capules are furnished with rings.

The *O. spectabilis* of North America, though at first considered as a variety of the *O. regalis*, is supposed by Willdenow to be a distinct species, having pinnules finely serrated. Both, when planted in a moist situation, are very ornamental, growing to the height of five feet. The *O. interrupta* of Willdenow is the *O. basilaris* of Sprengel; and, like the *O. claytoniana*, bears its fruit towards the middle of the frond. The *O. cinnamomea*, *O. japponica*, and *O. lancea*, have their fruit-bearing fronds differently shaped from the barren ones, and may eventually be found a distinct genus.

The genus *Osmunda*, then, evidently does not bear its capules on a separate spike, like the *Anemia*, but on the back of the fronds, which are changed in such a manner, in several of the genera, as to put on the appearance only of spikes. They approach, therefore, in their general structure, to those of the rest of the species, whose capules are annulated; and to the ardour and diligence of Humboldt and Bonpland we owe the discovery of an intermediate link between the genera without rings, and those that have them, in

**Polybotrya**, (Willd. 1853. Humboldt and Bonpland.)

(Intermediate genus.)

Capules with rings, sessile, round, aggregated in naked loose spikes.

There is but one species known of this truly interesting genus, *P. osmundacea*, which affords another, among many instances, of the fact, that the several links of the great chain of living natural bodies, are now, or were formerly, connected together, although we are generally only able to perceive them in that detached or dissénted form under which we endeavour to characterize them in groups. The ferns, therefore, whose capules are annulated, and those which are without rings, are not naturally distinct; and therefore we ought not to divide them into artificial classes, but endeavour rather, by tracing the organization of individuals, to collect and approximate the various groups of kindred genera, and thus restore them, as nearly as possible, to the place they really occupy in the series of natural affinity.

**IV. POLYPODIACEAE. (Plate CCLIV. Fig. 14.)**

In this tribe the genera have the capules nearly surrounded with an elastic jointed ring, which, as in all the others endowed with them, bend backwards on the bursting (see Plate CCLIV. Fig. 11.) of the ripened capule. In the whole of the genera, the capules are naked, or at least apparently provided with no other covering than numerous hairs everywhere around them. Brown, however, whom it is impossible to mention without praise, has in one genus, hitherto supposed to belong to *Polypodium*, demonstrated that these hairs are in reality the divided margin of a singular involucrum, whose capillary segments are incurved so as entirely to conceal the young, and even the mature capules, of the *Woodisia hyperborea* and *W. ilvensis*, so that this genus must be removed to the tribe *Cyathaneeae*, (see p. 349.) Whether similar involucra may not, some time or other, be detected in others of this very
heterogeneous assemblage, future careful examination must determine.

**Genera.**

(1.) *Acrostichum*, (Willd. 1954.)

Capsules covering the whole or the greater part of the lower disc of the fertile fronds, which frequently differ in shape from the barren ones.

Willdenow reckons sixty-two species, to which Brown (*Proc. Pl. New Hol.*) has added two hitherto undescribed, the *A. fraxinioides* and *A. pteroides*; the former species nearly related, he observes, to *A. aureum*, but different in having the pinnae shortly acuminate. The *A. aleicorne*, previously described by Swartz, was observed by Brown near Fort Jackson.

The species of this extensive genus are too numerous, and differ too evidently in appearance, to be accurately known; and it is easy to see that they require a more natural subdivision than, from our present imperfect acquaintance with their structure, can as yet be attempted with success. Some of the species would seem to approach to *Onoclea* in affinity. Genera, however, totally distinct, have been confounded with *Acrostichum*, from being examined in an advanced period of their fructification. Hence, as Sprengel observes, *A. hastatum* and Liljebad's *A. alpinum*, are real *Polyodia*, their capsules becoming crowded when about to burst. In many of the species, the fertile fronds, contracting, put on the appearance of spikes, seeming totally distinct from the sterile ones; and thus have been, even by modern botanists, confounded with *Osmunda*.

In the *Acrostichum aleicorne*, now in the public collection at Edinburgh, the sterile fronds are kidnap-shaped, entire, and sessile; while the fruitful fronds are erect, dichotomous, wedge-shaped at the base, bearing their capsules towards the upper part, on the lanceolate lacini. This singular species is figured by Schkuhr, (Crypt. 1. tab. 2.) By far the greater part of the *Acrostichum* are natives of tropical regions.

The *Acrostichum maranta* is the only European species hitherto described. This species has opposite bipinnate fronds. The pinnules entire, oblong, blunt, united towards the point of the frond, the whole of which is in the back covered with chaffy scales, as in *Ceterach*, from which, however, it is easily distinguished, by comparing them when the *Ceterach* is in the first period of fructification, and the transverse lines of its capsules are clearly seen. The *A. maranta* is found on the rocks of Styria, in the Tyrole, Switzerland, Italy, Spain, and Portugal. The *A. canariense* possesses great affinity with *A. maranta*; but it differs in being, in every respect, of double the size, the lower pinnae having nine or ten pinnules on each side, and the former being all alternate instead of opposite, as in *A. maranta*.

(2.) *Hemionitis*, (Willd. 1955.)

Capsules inserted into the reticulated vessels of the frond.

In this elegant genus, the fruit accompanies the ramifications of the veins, or rather vascular fasciculi of the frond. Willdenow describes fifteen species, in eight of which the frond is entire, and in the remainder variously pinnated. In the *H. acrostichoidea*, the capsules are confluent on the broad, lanceolate, undulated, and crenate pinnae. This species is native of Sierra Leone. The *H. reticulata*, figured by Sprengel, is evidently allied to *Vittaria lanceolata*, with the groups of capsules in branched lines, with which Brown thinks it ought to form a distinct genus. The *H. rufa* is the *Acrostichum rufum*, (Sp. Pl. 2. Lin.) This species a good deal resembles the *Asplenium tumensum* of Lamark (*Encyc. 2. p. 305*), from Brazil. The species are all natives of warm climates.

(3.) *Meniscium*, (Willd. 1956.)

Capsules in foliated groups, situated nearly parallel to each other, on the transverse vascular fasciculi of the frond.

There are six species are at present (1815) known; and to Sprengel we are indebted for a correct figure of the generic character, in an engraving of the *M. triphyllum*, (Anelit. tab. 3. f. 50.) Sprengel first characterized this genus, from its crescent-shaped groups of capsules situated on the ternary ramifications of the frond. The *M. triphyllum* is a native of the East Indies and of China. The most remarkable of the species was discovered lately by Humboldt and Bonpland in New Andalusia, the *M. arborescens*.

The stem of this fern is erect, and upwards of eight feet high; fronds pinnated, eighteen inches long; pinnae lanceolate, wedge-shaped at the base, two or three inches long, alternate, nearly sessile, and more or less minutely; the stipes smooth, green, about a foot long, and trisulcate above. This species possesses great affinity with the *M. reticulatum*, and with it probably will be found to constitute a distinct genus. The *M. reticulatum* is figured by Petiver (tab. 6. fig. 13.) It has not an erect stem. The *M. sorbifolium*, in its fronds, also resembles the *M. reticulatum*, but the pinnae are uniformly far more narrow and acuminate. It is the more useful to note these external resemblances, as they frequently point out the link of affinity in the genus. It is singular that Jacquin should have considered the last species as an *Asplenium*, (Collect. 2. p. 106, tab. 3. f. 2.) Both are found in Martinique; indeed, all of them, except the *triphyllum*, which is a native of the East Indies, are found in the West Indies and South America.

(4.) *Tetanitis*. (Willd. 1957.)

Capsules generally in linear, longitudinal, and continued groups, situated between the middle fasciculus and exterior margin of the frond.

This curious genus was formerly by Willdenow supposed to belong to *Pteris* (*Phytog. tab. 9.*) but it was very properly separated from that genus by Swartz, under its present designation. In fact, neither of the species, of which there are only two known, could be reckoned *Pteris*, as in neither do the fronds furnish an involucrem which is essential to that genus. Sprengel has a good figure (Pl. 10 Anelit.) of the generic character, in a pinna of the *T. blechnifolia* (See also Willd., *Phytog. tab. 9.*) The affinity of the genus with *Grammitis* is singularly evident, and it is better to refer such species as have the interrupted lines of capsules to that genus.

(5.) *Grammitis*. (Willd. 1959.)

Capsules in groups of longitudinal interrupted lines beset with scales, (Sprengel.)

This genus can scarcely be distinguished from the last, unless by the lines of capsules in them being straggling and interrupted, and nearly covered by scales. The greater part of the species known, have simple linear or lanceolate fronds. The *G. pauciloba* has linear foliaceous fronds, and a solitary line of capsules towards the point of them, along the middle fasciculus, or vein as it is usually termed. This can only be seen by a magnifying glass. (Swartz.) The frond of the *G. cle-
Capsules in transverse linear groups.

The _Ceterach_ has been so frequently described under different generic names, that it would seem to have puzzled the most eminent botanists. The _C. officinarum_, which is a native of Britain, and most countries in Europe, has had the various names of _Asplenium, Scopoldrium_ (Flor. Brit. 3. 113. and Roth. Germ. Grammitis, Swartz.) and now Willdenow has considered it as a distinct genus, along with two other species, the _C. canariensis_ and _C. aspidioides_. This last possesses the frond of _Atahirium thelypteris_, whilst the groups of capsules resemble those of _Asplenium_, without the involucrum. The transverse position of these groups sufficiently divide it from _Grammitis_; yet, like it, this genus has the capsules beset with scales. In both, however, these scales have no affinity with involucra, so far as yet discovered.

(7.) _Northolana_. (Br. Prodrom Nov. Holl.)

Capsules in continued or interrupted marginal groups, beset with scales or hairs.

Of this genus, Brown describes three species from New Holland. The _N. distans, N. vellera_, and the _N. pumila_. Besides the above, he observes, "hoc pertinent Acrostichum marantze, Pteris trichomanoides, et alia nonnullae inedita;" (Vitl. Prod. p. 145.)

(8.) _Polypodium._

Capsules in round distinct groups, in rows; more or less distant from each other.

The expediency of an accurate revision of this vast genus, which, by its present character, includes, according to Willdenow, a hundred and fifty-six species, is become obviously necessary. Can it be doubted that, in such an assemblage, differing so evidently in their structure, genera entirely distinct are necessarily included? The genus _Polypodium_, Brown justly observes, forms at present above a seventh part of the whole series. It is therefore much to be regretted, that the most eminent botanists of the present period, with some remarkable exceptions, are rather disposed to that close and unwearied investigation of individuals,—that patient and close inquiry into the structure of the fruit and seed, which are more than ever become indispensable to the accuracy of arrangement, not only of these, but of plants in general.

Since the judicious exclusion of _P. arvenicum_, (Flor. Brit. 111. 115; _P. hyperbororum_, Swartz.) the British species of this genus amount only to five. (1.) The _P. vulgare_, or common polypody. This species, like others of the series, is capable of living, and even thriving without any other moisture than what it derives immediately from occasional showers, or from dew; for we find it generally on old walls, towards the north, with its finely divided fibrous brown roots, penetrating the old mortar, along with various mosses, which probably serve to retain the moisture thus occasionally derived from the atmosphere. The scaly tortuous stem is succulent, and at intervals sends forth its pinnatifid pointed fronds, the lobes of which are serrated and blunt. These lobes produce the brown round groups of capsules in a single row, on each side of the middle fasiculus of the fronds, which alternating on each side of the stem, extend from a span to a foot in length. The most remarkable variety is that noted by Bolton, in which the pinnae are formed into branches resembling the maternal frond. This species is doubtfully, but probably, figured by Bolton, (tab. 2.) It is also figured by Morison, (sect. 14. tab. 2.) under the name of _P. Cambr-Britannicum, pinnulic laetiacinis_. This is like some other ferns, well adapted to adorn rocks surrounded with shrubs. (2.) _Polypodium? (an Atahirium?) fontanum_, fronde lineari lanceolata, acuta, pinnata, pinnis cordatatis obtiusiusculis pinnatifidis crescentis supra glabra, (Sm. Flor. Brit. 3.) Smith thinks this species distinct from the _Aspidium fontanum_ of Swartz. (3.) _P. phegopteris_, (Wild. Sp. Pl. 151.) The frond is pinnate, the pinnae lanceolate, pinnatifid and united at the base, the under pinnae bent back. This species is found in Lapland, and in the woods of most parts of Europe. (4.) _P. dryopteris_, (Fl. Brit. 5.) This species is the tender three-branched _Polypody_ (Eng. Bot. 616.) (5.) _P. calceolum_, (Wild. Sp. Pl. 136. and Fl. Brit.) In this species the ternate bipinnate frond is erect, and more rigid; in other respects it resembles the last. It is the rigid three-branched polypody, and is figured by Bolton, as _P. dryopteris_, (53 tab.) Our British species then of this genus are very limited; but, indeed, we possess nearly the whole of the European species yet known.

In order, however, to give some idea of the very dissimilar habit of some foreign species of this extensive assemblage, it may be remarked, that the _P. lycopo- doides_, (Wild. Sp. Pl 12.) possesses entire lanceolate fronds, and an elongated creeping stem, covered with chaffy scales, from which it has its name; although it has but little resemblance to _Lycopodium_. Plumier, (Amer. tab. 42.) gives an expressive figure of it, under the denomination of _lingua cervina scandens_. It abounds in the woods of all the West Indian Islands. The _P. undulatum_, (Wildld. Sp. Plant. 25.) possesses linear lanceolate, very entire fronds, above an inch broad, and extending to the length of twelve inches, undulated on the border, and narrowed both at the base and point; the ramified veins extending nearly in a longitudinal direction, parallel to each other. The _P. longifolium_, (Wild. 26.) has similar fronds, extending to the length of eighteen inches. Both these species are covered on the under side with white woolly down. The _P. tanisium_, (27 Willld. Sp.) was discovered by Humboldt and Bonpland in South America, near Caripe. The fronds of this fern are also linear, little more than half an inch broad, and extending to the length of two feet, with the base very much attenuated. The _P. far- ciale_ of Willdenow, (Humboldt and Bonpland,) is figured by Plumier, (Filicae. t. 127.) A nearer examination of these kindred species would, perhaps, warrant their being considered as conegers of a genus distinct from the _P. aureum_, and others deeply pinnatifid, such as the _P. dulce_, _P. decumanum_, and other kindred species. As to the _P. hyperbororum_, (128.) and _P. ivesiae_, (129.) it is evident both must be excluded from this genus, if we attend to the valuable memoir of Brown, published in the eleventh volume of the Linnean Transactions, (p. 170.) in which he has demonstrated the true nature of these singular ferns. To the species described in the present edition of the _Sp. Plant._ (1810,) six others hitherto unknown are added by Brown, (Prod. Flor. Nov. Holl. 145, 146.) (1.) _P. confluens,
with linear entire lanceolate fronds, ash-coloured beneath, with the groups sometimes confluent, and a scaly creeping stem. (2.) P. attenuatum, likewise with linear lanceolate fronds, attenuated at the base, and a creeping stem. (3.) P. membranifolium, with a pinnatifid and reticulate frond, and minute scattered groups of capsules. (4.) P. diversifolium, the sterile fronds sessile, ovate, and sinuate; the fertile ones pinnate with lanceolate, ensiform, crenate, and subpinnatifid fronds. (5.) The P. rupestris, apparently possessing affinity with P. stellatum of Swartz.

V. ASPIDIACEÆ. (Plate CCLIV. Fig. 15.)

This tribe was originally included in the genus Polypondium of Linnaeus, but since the more accurate examination of the genera begun by Sir James Edward Smith, and continued by Swartz and Bernhardi, the polypondium has been divided into several more natural and distinct genera, whose groups of capsules, although separate, and in round spots, are covered with an involucrem, which in some of them is umbilicated and reniform, fixed at the centre, opening all around; and, in others, attached by one, and opening on the opposite side of the involucrem. Without, therefore, implicitly following Roth, there seems to be a certain degree of propriety in adopting his principle of separating these genera, although he erred in confounding them with the Cyatheae of Smith, which belongs to a very distinct tribe. But since the publication of Sprengel’s work, a genus totally distinct has been discovered by Humboldt and Bonpland in Mexico.

Genera.
(1.) Pleopeltis. (Willd. 1861. Humboldt and Bonpland.)

Capsules in round scattered groups, with numerous peltate involucra to each of them.

P. angustata. The stipes of this small fern is smooth, and about an inch in length: the frond, which is deeply pinnatifid, wedge-shaped at the base, and decurrent, is two or three inches long; covered thinly with brown scales. On the back are about the size of mustard seeds, and to each of them there are about twenty of the brown peltate involucra. These distinct involucra separate this genus from the two following, but their form rank it with this tribe in affinity.

Capsules in scattered round groups, invested with a round or reniform involucrum fixed in the centre, and opening all around.

Swartz and Willdenow (Sp. Pl. 5.) have united this genus with Athyrium, (Polystichum, Roth and Lamark); but to us, the reasoning of Sprengel for keeping them separate, seems unanswerable. For, if the form and opening of the involucra be, as it is at present, the only characteristic principle of the generic character, we ought, in consistency, to adhere to it, until a better founded be discovered. The Aspidium, then, includes such genera as have their involucrum fixed in the middle, and emit their capsules all around.

Among the British species, are, 1. The A. fitx maf, which affords a decided example of this genus, so as, even without the help of glasses, the kidney-shaped shields may be easily perceived opening around the edges, and discharging the brown capsules. This species, whose elegant bipinnate fronds, from upwards of twenty inches to two feet long when in a proper soil, ought to become more frequently an ornament of the shrubbery, possesses pinnules rounded at the extremity, finely serrated, and bearing in the end of summer the groups of capsules, in two rows, on the under side near the middle rib; the stipes densely beset with chaffy scales, and the stem, evidently short and near the surface, is hid by the remains of the decayed stipes, and generally confounded, even by botanists, with the roots, from which, however, it is totally distinct; for the roots are fibrous, discharging at intervals, from the stem. It is singular that this species should be so generally diffused. It is a native not only of every part of Europe, but of the woods of Asia and the North of Africa; and, what is singular, Willdenow relates that he possesses a specimen of a variety from the island of St Thomas in the West Indies. This variety is in length the same as the common European species, but the pinnule are serrated only towards the end; and, in every respect, it closely resembles a variety found in Germany. There is another small variety found in poor mountainous situations.

2. A. fragrans, with bipinnate fronds, primary lobes, ovato-lanceolate; secondary, narrow, toothed, their tender surface covered with the involucrae, and scaly. This species emits the odour of raspberries. Is it Aspidium oreopteris? (Smith’s Flor. Brit.). It was found by Hudson in England. This species also deserves a place in the shrubbery.

4. A. atlataenum, (Willd. Sp. Pl. 100; Smith’s Flor. Brit.; Schkuhr, Crypt. tab. 4.; Bot. 28.) The frond is bipinnate, pinnules elliptico-lanceolate, with soft spines beneath, and much resembling the last; but the fronds are more rigid and shining. Pinnule very close, and the pinnules more elliptical, and less cut. It is figured in Eng. Bot. 1460.

5. A. lonchitis. Fronds pinnate, with lanceolate, ciliated, and serrated pinnule, and scaly stipes. The fronds are about a span long, erect, lanceolate, and narrow. Pinnule nearly sessile, alternate, declining, acute, and spinulose: at the margin of capsules, frequently confluent.

6. A. oreopteris. The frond is pinnate, with the pinnae pinnatifid, very entire, and the groups of capsules confluent on the margin. This species is figured by Bolton under the name of P. thelypteris, tab. 22, but far better in Eng. Bot. 1019. To these, Brown has added four new ferns, under the designation of Nephroidium, (Mich. Flor. bor. Amer.) 1. N. oblitteratum. 2. N. unitum. 3. N. decompositum. 4. N. tenue. The Nephroidium seems to possess entirely the character of Aspidium. (Prodr. Nov. Hott.)

(3.) Athyrium. (Aspidii species, Willd. and Smith’s Flor. Brit.)

Capsules in small round groups dispersed on the whole of the lower surface of the frond, covered with an involucrem attached by one, commonly the inner side, and generally opening towards the margin.

1. The Athyrium (Aspidii, Willd. Sp. Pl. thelypteris, whose fruit is figured in Plate CCLIV. Fig. 11, affords a clear idea of the generic character as distinct from Aspidium. A. thelypteris has fronds nearly bipinnate, the pinnae somewhat crenate and pinnatifid, distinct at the base, and decussated. The groups are confluent. The frond is erect, a foot high, lanceolate, and of a bright
green colour; the stipes are smooth and elongate; the pinnae are opposite, but distinct and sessile at the base, lanceolate and pinnatifid, generally smooth; the lobes somewhat crenate at the point.

2. A. filiz isina, with a bipinnate frond; the pinnae serrated, pinnatifid, with a smooth stipes and reniform involucre.

The fronds of this species are eighteen inches long, broadly lanceolate, of a deep green colour, smooth as well as the stipes; the pinnae are lanceolate and pinnulate, and these pinnae again pinnatifid. The groups of capsules are disposed as in Aspidium filiz mar, but oblong and much less. It thrives best in moist and shaded places. The Polypodium incisum of Hoffmann, is a variety of this species. Roth's Athyrium oontum is another variety; and Muller's figure (Flor. Frud. t. 2. f. 3.) is an excellent resemblance of it, to which Roth refers for his A. oontum. The A. trifidum of Roth and Hoffman, with very broad fronds, and the stipes beset with chaffy scales, is in fact another variety. This species is figured by Morison, (sec. 14. t. 3. f. 8.) and Fluk. Phyt. t. 180. f. 4.

3. Ath. montanum. (Aspidium, Willd. 147.) With more than twice compound ternate and tripinnate fronds; lobes remote, and the last ones very narrow; blunt at the tip, and acutely serrated. Pluknet found it in Wales. (Phyt. t. 89. f. 4.; Allion, Fl. Pedmon. 2110.)

Allantodia, (Intermediates.) (Brown, Prodr. Nov. Hol. 149.)

Groups of capsules oblong, oblique, with respect to the rib; involucrum arched, originating laterally from a vein to which it is attached by both margins, and opening on the inner side.

This genus seems to be intermediate between Athyrium and Asplenium, and certainly distinct from both, although more allied to Aspidiaceae.

Allantodia, Brown observes, is, in habit, intermediate between Nephrodium, (Aspidium, Sprengel), and Diplazium. There are two species discovered by Brown. The A. australis, with bipinnate, deltoid, faccid, membranous fronds, and pinnatifid pinnae; attenuated towards the point, and oblong, blunt, serrated lobes, bearing numerous capsules under the oblong involucre. The A. tenera resembles the last, only the lobes bear their linear groups of capsules at the base only.

VI. ASPLENIACEAE. (Plate CCLIV. Fig. 16.)

The Asplenium trichomanes, a figure of part of the frond of which is represented in the Plate, may be assumed as affording the type of this tribe. It includes the Camopteris of Bergius (Darea, Juss. and Willd. Sp.) which Brown observes differs only in having the pinnae deeply cut, narrow lobes, and hence the involucre close on the margin, and opening outwardly with respect to the lobe, but inwardly with respect to the rib, from which the fructiferous vein originates. There are also some species, whose fronds, partly answering to the character of Asplenium, and partly to Camopteris, and even in the same involucre, exhibiting the character of both. Of their affinity, then, there can be no doubt. In all the Asplenias, adds Brown, I have observed the involucre originate from the superior branch of the vein, and always opening (liberum) towards the rib; this, he observes, is the most natural structure. Provided, however, it is situated on an inferior branch, which occasionally hap-

pens in certain species, whose fronds are undivided, the involucre opens in a contrary direction.

Genera.

Capsules in linear submarginal groups. Involucre originating from lateral veins, and opening towards the rib.

There are none of the species of Darea hitherto found in Europe; most of them being native either of the Cape of Good Hope, Bourbon Island, or New Holland. This genus was first established by Bergius under the name of Camopteris. The lines of capsules are generally situated in the marginal sinuses of the narrow lobes of the frond. The generic character is represented by Sprengel, in his third Plate, exhibiting part of the frond of D. odorantes. Sometimes, however, the groups are at a greater distance from the margin. The D. samaroides lately discovered in Caracas by Humboldt and Bonpland, to whom all the physical sciences owe so much, is a most beautiful species. The stipes are smooth, channelled, and half a foot long; the frond from three to five inches; bipinnate, the pinnae and pinnule alternate; the pinnule are linear, obtuse, and bipartite, with bipartite laciniae.

The D. rhizophylla is figured by Sir J. Edward Smith, Camopteris rhizophylla (icon. in edit. tab. 50.) is a native of the West Indies. The D. vinipara, which is figured by Bergius, (Act. Petrop. G. tab. 713.) affords an instance of buds being produced from the pinnule of the frond. This fern is found in the woods of Mauritius and Bourbon Islands.

Capsules in linear separate groups, originating laterally from a vein, and opening towards the rib.

Wildenow describes about one hundred of this genus, of which only eight are natives of Britain.

1. A. trichomanes. The stem of this elegant species is very short, enveloped with the decayed stipites of former years, and having in the centre of these the buds of the future season. The pinnae of the frond are oval, finely crenate, with a stipule of a shining purplish hue, carinatus in the under side. It is generally found on the northern walls of our ancient buildings, where, although it requires but little moisture, it is in some measure protected from the total want of it. It is correctly figured by Sowerby in Eng. Bot. 376, and by Woodville, Med. Bot. tab. 204. A syrup was formerly prepared from a decocation of it, the whole plant possessing a slight astringency; but other ferns far exceed it in the proportion of sweet mucilaginous matter, abounding not in the frond, as Woodville observes, (Medical Botany, ut supra), but in their stems. Mr Teasdale found a variety of this fern with the frond branching.

2. The A. viride resembles the last, but differs, having a green quadrangular stipites; the pinnae of the frond alternate, and of a paler green; the middle fascicle of the frond is occasionally bihid.

3. A. marinum. This species has also alternate pinnae, ovate, blunt as in A. trichomanes, and of a deep green colour, wedge-shaped at the base, and above sometimes united. On several parts of our coast, and in the sandstone caves at Wemyss in Fifeshire, observed by Sir Robert Sibbald. These three beautiful species possess an evident affinity with each other.

4. A. alternifolium, with a pinnate frond, and alternate, erect, wedge-shaped pinne, eroded at the point.

2v
In this species the lines of fruit are less numerous, shorter, and paler than in the first described species. It is figured by J. Jacquin (Misc. t. 5. f. 2.)

5. A. crenulatum. In this species the frond is bipinnate and pointed; the pinnules obovate, dentate, and acuminate. It is native of the south of Britain, and found by Mr Forster on the rocks at Tunbridge. It is about a span in length, the lines of capsules short, and few in number.

6. A. adiantum nigrum. With deltoid fronds, alternately tripinmate, and with lanceolate, cut, and serrated pinnules; figured by Bolten, fol. t. 17. There is a variety with fronds longer in proportion to their size. It is found on old walls, and at the roots of old trunks of trees. The smaller variety was found in a dark cave in the mountains of Mourne in Ireland, and in this variety the fronds are barren and membranous, elegantly laciniated.

7. A. septentrionale, with a trifido-pinnate frond, and linear alternate pinnas, as it were torn at the point. It is found in the fissures of the greenstone, and other rocks in the neighbourhood of Edinburgh, where Wil- liseul found it in Riat's time.

8. A. ruta muraria, with the frond alternately decomposed, pinnia rhomboidal open craded at the point, elegantly figured in Eng. Bot. t. 150. We have succeeded in obtaining germinating seeds of this, and other ferns, and found the experiment answer best in decayed mortar mixed with vegetable mould, taken from under the parent plant in ancient ruins.

Among numerous foreign species, the A. fragrans (Wild. Sp. 594. Hort. Kenn. 15.) merits attention. This species has bipinnate fronds, and oblong acute pinnules, serrated at the point; but it is chiefly remarkable on account of its agreeable colour, resembling that of Antheranthum odoratum.

The A. rhizophyllum (Wild. Sp. Pl.) possesses, like certain other ferns, the property of emitting roots from the fronds, which are lanceolate, suberenate, and auriculated at the base, and the buds germinate from their very long linear filiform points. This species, though perfectly hardy, is in few collections. It was introduced into Britain about a century ago by Mr John Bannister.

The A. monanthemum, a native of the Cape of Good Hope, is another singular species, having a solitary group of capsules on each pinnule. It was introduced in 1790, by Messrs Lee and Kennedy of London. To the species already described by Labillardiere, as native of New Holland, Brown (Prodr. p. 150.) has added the following new species unknown to Willdenow, viz.

(1.) A. attenuatum, with linear fronds, pinnated at the base, and entire above, and, like the last, radicant at the attenuated point. (Fort Jackson.)

(2.) A. oblongifolius, with ovate, rhomboid, dentate, striated and pinnate fronds, with a chaffy stipite, the point of the fronds also radicant; a circumstance common to several New Holland species, and which shews the absurdity of naming species from properties supposed peculiar to one.

Genera (insulated) of uncertain affinity.

Capsules in oblique linear groups, parallel to each other, between the secondary veins of the frond. Involucrum double, opening by a longitudinal fissure.

It is to the genius and accuracy of Sir J. Edward Smith, that we owe the separation of this and other genera of ferns from those originally established by Linnaeus. Although before the reformation of the genera begun by him, this was without any accurate examination ranked among the Asplenie, with which, however, it seems to possess very little affinity:

1. Scopoliendra officinalis, is a native of Britain, the stem is black, as in several other ferns, and seamy and short. The fronds, from ten inches to a foot long, according to circumstances, tongue-shaped, entire, and cordate at the base, and narrowed at the point; of a peculiarly firm texture, probably from the numerous transverse ramifications of the rib, or central fasciculi; smooth, and of a bright green colour. The stipites are of a dark brown colour, and very often scalar. The variations on the waved margin of the frond, or the occasional lobes produced at the point, are the effect of situation. Although, like the rest of the series, it will grow on the most elevated ruins, in the crevices of the stones, it attains a large size on a richer damp mould.

2. Sc. hemionitis, bears great resemblance to the last; the base of the frond, however, instead of being cordate, is hastate, that is to say the lobes are angular rather than rounded below, like those of the first species. This fern is figured by Cavaillles, Ann. de Sciences Natur. tab. 41. and Morison, sect. 14. t. 21. f. 2.

Capsules in distant double lines, simple, or branched. The involucra double, each opening towards the margin of the frond.

Willdenow describes ten species of this genus, which, although in habit somewhat resembling certain Asple- nia, is too distinct from them to be considered of the same tribe. Like Scopoliendra, it possesses a double involucrem, opening in a manner the reverse of that genus. It remains, therefore, for future observation, to enlighten us as to the real place these, and no doubt other genera, really occupy in a natural series. In the mean time, we are much indebted to Swartz, Bory de St Vincent, and Willdenow, for all as yet known of the species. The D. plantago-norma is figured both by Swartz and Schkuhr, (Swartz, Syn. 91. tab. 2. and Sch. Crypt. tab. 86.)

The D. ascendentum is a native of the East Indies, and Willdenow in his definition of this species has corrected an error of Swartz, in describing it as bipinnate, Swartz having only a pinna, which he mistook for the entire frond. This species derives its name from the stem abounding more with that sweet gummy sap, which is common, as already observed, to the greater part of the series, even in Europe.

The D. arborescens, (Callipetis, Bory. Ill.) is an elegant species, inhabiting the woods of Isle de Bour- bon. The fronds resemble the most magnificent of those of palms, extending from four to six feet, or more; in length; and even the alternate pinnae are from eighteen inches to two feet long; the pinnule three inches, the superior ones gradually lessening. The groups are linear, and decussated. It differs from the last in having an arborescent stem, and in the division of the fronds, although it is evidently nearly allied to it.

(3.) Vittaria. (Sm. Act. Taur. Wild. 1971.)

Capsules in continuous marginal or dorsal lines; the involucrum double, and of the texture of the frond; the one opening outwardly, and the other inwards.

Of the eight species described by Willdenow, the greater part have linear membranous, pendulous or filiform fronds.
In the *V. filiformis*, which is a native of Peru, the fronds are two or three feet long, and only half a line broad; and in the *V. zosteraria*, the stem is of the thickness of a goose quill, covered with chaffy scales, and the frond, extending to the length of five feet, is pendulous, and only three or four lines in breadth; and never, perhaps, was a species seemingly better named, if similarity is regarded, for it has quite the appearance of *zosteraria* marina.

The *V. ensiformis* and *V. plantaginea* have erect fronds; and the lanceolata, it has been already observed, seems to belong, with *Hemionitis recticulata*, to a distinct genus. This fern is figured by Schkuhr, (Crypt, tab. 101.) According to Brown, the *V. elongata* is a native of New Holland, though also of the West Indies, according to Swartz.

VII. BLECHNIDAE. (Plate CCLIV. Fig. 17.)

The genera of this tribe resemble each other in habit, and in the arrangement of the groups of capsules. In *Blechnum*, the lines of these groups are continuous; whilst in *Woodwardia* they are interrupted; but in both genera they are parallel on each side of the rib of the frond, and in both the involucre opens inwards or towards the rib; indeed, both genera were confounded until separated by Sir J. Edward Smith. The affinity of *Doodia* and *Stegania* is equally manifest with the former.

**Genera.**

1. (1.) *Woodwardia*. (Sm. Act. Taur. 5. tab. 9. fig. 5.) Willd. 1793.

Capsules in short interrupted, or oblong lines, on each side of the middle rib. Involucre arched, opening inwards.

An accurate idea of the generic character, is afforded by Sprengel in his fourth plate, fig. 29, (vid. Intro. to Crypt. Plants) representing *Woodwardia japonica*, (his Bl. Japonicum.) Of the seven species enumerated by Wilkedenow, only one, *W. radicans*, is a native of the south of Europe. Of this, there is a figure by Schkuhr, (tab. 116.) and of a variety, (tab. 113.) The rest are all natives of warm climates. Brown (Prodr. Nov. Hol. p. 151) has arranged *W. candida* of Wilkedenow, with two additional species from New Holland, in a distinct genus, under the name of

Capsules in lunulate or linear groups, in rows parallel to the rib. Involucre originating from an anastomosing branch of a vein, plane, and opening inwards.

This genus is nearest to *Woodwardia*, and, as Brown observes, has an equal affinity with it, as *Asplenium* has with *Allantodia*.

The designation *Doodia* he conferred on this genus, in memory of Samuel Doodly, an apothecary of London, who was among the first botanists who investigated cryptogamous plants.

3. (3.) *Blechnum*. (Lin. Smith, Swartz, and Willd. Sp. 1792.)

Groups linear, longitudinal, continuous, parallel to each other on both sides of the middle rib of the frond. Involucre opening inwards.

The *Blechnum* is at once distinguished by the continuous lines of the capsules, parallel with, and close to the rib on each side. Of the twenty species described by Wilkedenow, the greater part are natives of the tropics. The *Blechnum occidentale* is common in every collection, as it thrives better in the stove than many other foreign genera. It has been for several years kept among those of the botanic garden at Edinburgh. The *Blechnum boreale* is the only species hitherto known to be a native of Europe, and, what is singular, it is also found in the Canary islands, but of course only in alpine situations. The linear narrow fertile pinnae, no doubt contracted and exhausted by nourishing the fruit, caused it formerly to be confounded with *Gimnada*, under the ridiculous term *Spicant*.

Groups linear, continuous, the capsules at length covering the back of the contracted frond, and of the pinnae. The involucre scarious, opening inwards.

None can peruse the brief notes of the author of the *Prodr. Nov. Hol.* without being reminded of the learning and judgment of the author. These notes, like those of Jussieu, (Gen. Pl.) generally in a few words convey a degree of information that could only be obtained by a patient and diligent enquiry into nature. The *Stegania*, he observes, possesses nearly the habit of *Blechnum*, to which it is next in affinity; although in character it approaches to certain *Pteris*, at least some that are at present reckoned to belong to *Pteris*. The *Blechnum procerrum*, indeed, of Swartz and Labillardiere, with the *Onoclea nuda* of the last named author, ought to be ranked as *Stegania*. To these, however, he adds six hitherto unknown species; the *St. pateroni*, *lanceolata*, *fuscisiliis*, *alpina*, *falcata*, and *minor*. Of these, *St. pateroni* has undivided fronds, the sterile ensiform and crenate; and the fertile fronds linear; the remaining species being all pinnatifid, or pinnately. The *St. nuda* (*Onoclea, Lab.*) is figured by Labillardiere, (Nov. Hol. p. 96, tab. 245) and the *St. procura*, (Blechnum, Lab. p. 96, tab. 247.) But, alas! when Brown will be enabled to publish his fine drawings of these and numerous other rare plants, it is impossible to foretell. After these species, if striking affinity is to be regarded, *Stegania onocleoides*, (Pteris crispa, Willd. Sp. 395.) must be added as intermediate between *Stegania* and *Onoclea*.

VIII. ONOCLAEACEAE. (Plate CCLIV. Fig. 18.)

Wilkedenow having, in the last edition of the *Species Plantarum*, arranged the former *Onoclea* under three separate genera, all of which possess a close affinity, there can be hardly a doubt as to the propriety of arranging them as a natural tribe. Wilkedenow's genus *Onoclea* now contains only one species, the *O. sensibilis*; but on the authority of Brown, (Prodr. 152.) *O. struthiopteris* is added to this genus, and consequently the *O. pensylvanica*. (*S. pensylvanica* of Willd.) In all of them the involucre is formed by the reflex margin of the frond.

**Genera.**

1. (1.) *Onoclea*.

Capsules densely covering the under part of the frond. Involucre consisting of the reflex margin of the frond, and opening inwards.

The definition of this genus by Swartz is to be preferred to that of Willkedenow, until it is ascertained whether the "*industria non desidientia*" be really analogous with the involucre heretofore supposed to be characteristic of *Onoclea*, as figured in our Plate, and expressed in the generic definition.

1. *O. sensibilis*. This singular species is a native of America, and was introduced into this country in the year 1699, by Bobart. It endures the climate of Britain in the south. The sterile fronds are pinnate,
the pinnas as it were cut, but united towards the extremity of the frond; the fruitful fronds are bipinnate, the pinnules being folded back in a globular form. This fern possesses the singular property of withering soon after being touched by the hand. Sprengel thinks, that the perspirable matter exerts this deleterious influence on the plant, as he repeatedly touched it with other bodies without injury. A figure of it is given by Morrison, vol. iii. sect. 14. tab. ii. fig. 10.

2. O. struthioperis, (Struthioperis Germanica, Willd. Sp.) This species is one of the rarer European ferns. It occurs in the shady forests of Germany and the Tyrol on mountainous situations, and, also in Sweden and other northern parts of Europe. It is figured in Flor. Dan. tab. 169; but this figure is not very well executed.

3. O. pensylvanica, (Struthioperis Pensyle. Willd. Sp. 5. 289,) is another species very like the last, but different in having the pinnae rounded and blunt, and the undermost acute, and longer. O. nodulosa of Swartz is, according to Brown, (Prodr. ut supra,) a Woodwardia, (Woodr. onocleoides, Willd. Sp. 1073.)

OnocleaI. Sp. Bory and Swartz.)

Capsules densely covering the inferior part of the frond. Involucrum continuous, marginal on each side of the frond, and opening inwards.

Of this genus, Willdenow describes eleven species, all of which are taken from the Onoclea, (Synops. Fil.) and Labill. (Nov. Holl.) and Bory. (Hinn.) In affinity, they approach so near to Onoclea, that it is difficult to give them a determinate and distinct character, as must be the case in all natural genera, when the intermediate links of the series are discovered. The involucrum is continuous on each side of the frond, and approaching nearer to that of Pteris than of Onoclea itself. The most magnificent of the species is the O. Borgia, so named as a just tribute to this celebrated botanist. It is figured by Bory. (Hinn. p. 194. tab. 3.) himself. He found it in the barren mountainous parts of the island of Bourbon, and he gave it the name of Pteris osmundoides. The sterile fronds are pinnate; the pinna sessile, oblanceolate, and very entire. The fruitful fronds are also pinnate, and the pinnae are linear, and entire. The stem is erect, and four feet high. The sterile fronds are two or three feet long; the fruitful ones shorter, and their pinnae very narrow. This fine species, like most of the other arborescent ferns, is unknown in our collections. Willdenow is in doubt whether the L. scandens be not an Acrostichium, to which, in some measure, the Lomaria approaches in appearance. The Lomaria variabilis was also reckoned an Osmonda by Bory, (O. trifrons,) as well as the L. fraxinea, (Willd.) from his not observing the ring of the capsules.

IX. PTERIDÆÆ: (Plate CCLIV. Fig. 19.)

The genus Pteris, here assumed as the type of this tribe, is at present by far the most extensive of the whole series. Willdenow having, in the (Sp. Plant. 5.) described a hundred and eight species; and although Dryander had previously, from a more accurate examination of the structure of the involucrum of certain species, with great judgment separated from it the Lindaea, there is scarcely a doubt but future observers will be enabled still farther to analyze, and more distinctly arrange, the kindred species of this numerous assemblage. Brown, whom we have had occasion so frequently to quote, has already observed, "Pteris thalictroides distinctissimum genus constitut." Pteris crispus, is, in fact, of a distinct genus, and has been already placed by us as a species intermediate between Stegana and Onoclea, until future observers be enabled to detect its unknown associates. Pteris auriculata of Thunberg, in which the arched involucrum includes the groups of capsules in an inflexed margin, must in like manner be distinguished as a genus; already therefore the present Pteridae may be presumed to be a great natural tribe, including several distinct though kindred genera.

(1.) Lindaea (Dryander, Act. Soc. Lit. 3. p. 40. et

Sin. Act. Taur. tab. 5.)

Capsules in continuous lines, and frequently very near the margin of the frond. Involucrum scarious, originating from the under membrane of the frond, and opening outwards.

It is to the late venerable Dryander, that we owe the distinction of this genus from Pteris; for both Anblet and Swartz had associated the respective species with Adiantum; although they ought, he observes, in consistency with the Linnaean character, to have been referred to Pteris, with which indeed they have an evident affinity. Lindaea received its name in honour of Lindsay, an ingenious botanist of Jamaica. Dryander (Trans. Lit. Soc.) describes nine species of great beauty, and diversity of form.

The L. reniformis, a singular species, (Lin. Tr. fig. 1. ut supra,) has an entire reniform frond, without the smallest indentation, the stipes being attached to the sinus, formed by the two lobes of the frond. It is to be regretted, that in the eight species described by Dryander, we have not the stem, as the examination of the frond alone is insufficient to ascertain completely their habit. The L. tenacra, likewise figured by Dryander, possesses great beauty. The frond is tripinnatifid, and the pinnae elegantly cut into obsolete or rhomboidal forms.

In no genus are the ramifications of the vascular fascicles from the stipes more beautifully displayed than in this.

To the eight described by Dryander, Willdenow has added twelve more from Bory, Labillardiere, Swartz, Humboldt and Bonpland; and to these Brown (Prodr. p. 156.) has added L. ueda, with deltoid bipinnate fronds, and conicaceous, obovate, rhomboidal pinnales, lobed in the under part; and elsewhere entire. The sterile fronds are serrated at the point, and have a quadrangular stipes. This species, like most of the others, inhabits the tropics.

(2.) Pteris.

Capsules in continuous marginal lines; and marginal scarious involucre, originating from the inflexed upper membrane of the frond, and opening inwards.

The species, P. lanceolata, and P. piloselloides, according to Brown, belong to Tamiui, and, with Blechnum seminatum, Onoclea speciosa (Sw.), ought to be transferred to that genus.

The following species are natives of Europe.

1. P. ensifolia. This species has pinnate fronds, with very long sessile, lanceolate, tapering pinnae, and a creeping stem. It is found in Spain and Algiers, and figured under the name of Polypodium majus, (Barr. Ic. iv.)

2. P. cretica, with pinnate fronds, and the pinnae with short footstalks, lanceolate and acuminate, narrow and serrated at the base; the undermost bipartite or ternate; figured by Schkuhri, Crypt. 65. tab. 50.

3. P. palustris, with pinnate fronds; petiolated, oblong, lanceolate, and pinnatid pinnae; lacini
lanceolate, subcrenate at the point. Native of Portugal, and figured by Tournefort. (Inst. tab. 513.)

5. Pt. aquilina, with a bipartite frond; the branches bipinnate; pinnae linear lanceolate; the uppermost undivided, and the undermost pinnatifid, with oblong obtuse lacinia; figured by Bolton, (16, tab. 10; Schkuhr, tab. 96, Crypt.) It is singular, that this species should be so much dispersed. It is found in the barren woods and down of Europe, Asia, and North America. The variety figured by Schkuhr, (tab. 96), originates from disease, the frond being infested by fungi, (Sphaeria). This fern affords an instance of the subterramous stem common to many ferns and various other plants, particularly the Gramineae. On cutting across the stem, the vascular fasciculi have been imagined, by the superstitious, to resemble a cross; others have compared this appearance to a spread eagle; and the name has been derived from this circumstance, according to some. But probably the remarkable appearance of the pinna of the frond, extending occasionally to nearly five feet in length, has given rise to the name.

There are certain foreign species of Pteris with erect arborescent stems, particularly the

(1.) Pt. aculeata (Willd. Sp. Pl. 5.) with bipinnate fronds, and oblong acuminate pinnatifid pinnae, with lanceolate pointed and serrated margins. The magnificent stem, and the stipes, are both thorny. It is figured by Plummer, (Plantes de l'Ameleque, tab. 3.) and is native of the West India islands, particularly St Domingo (Hayti) and Jamaica.

(2.) Pt. escucentia, with a tripartite frond and bipinnate branches, linear, obtuse, crenulate, rigid, decurrent pinnae, the undermost subpinnatifid. This species is found in the woods of the Society Islands, and of New Holland. The best figure is that of Schkuhr, (Crypt. tab. 97.) The term escucentia is far from being appropriate, as many of these plants abound with similar sweet mucilaginous matter in the cellular substance of the stem. See also Br. Prod. Nov. Holl. p. 154.

Brown has also described three new Pterides, approaching in habit to Adiantum, viz. Pteris falcatia, Pt. nittida, and Pt. nudicaulis. Vid. Prod. ut supra.

(3.) Adiantum.

Capsules in punctiform or linear groups, and inserted into the involucrum formed by the inflexed margin of the frond, and opening inwards.

This genus possesses so clearly an affinity with the one just described, that they, as it were, pass into each other by the Pteris adiantoides, just mentioned, of Brown. In this case, we have an instance of what is seldom met with, the natural series in a connected state, and not disjointed and scattered, as we generally find it; so that if the Pteris and Adiantum cannot be well defined, our view of the series is on that very account the more complete. In offering a general sketch of the genus, then, the species approaching nearest to Pteris ought to be noticed first; but the want of a closer examination of certain species than has hitherto been made, renders this a most difficult task.

Of upwards of fifty species described by Willdenow, only one has hitherto been found in different parts of Europe, and we possess it also in Britain, the A. capillus ven-

ers. In this fern, the frond is alternately decoupled, the pinnae, with footstalks, in wedge-shaped lobes; the involucrum are kidney-shaped. It is figured by Bolton, (tab. 29.) This elegant species is, like some others, dispersed not only over Europe, but is found on Teneriffe, Jamaica, Isle de Bourbon, and South America. It varies much in size.

Of the foreign species there are three with simple kidney-shaped fronds, the A. reniforme, and A. Asarifolium of Willdenow. The first is figured by Plutenet (Atn. tab. 287, fig. 5.) and the second by Lamarck, (Illustr. Gen. tab. 80), and Schkuhr, (tab. 116.) Both these resemble each other very much; the frond of the first is, however, crenate; and of the second, very entire, and broader than long. The third, A. philippine, is represented also to have a simple frond; but it is figured by Petiver laciniatum, (Gaz. ph. tab. 4. fig. 4.)

Of the Adianta with pinnate fronds, the Rhizophorum affords another instance of the naked elongated point of the frond containing buds, producing new plants. Himboldt and Bonpland found several new species of Adiantum in South America, particularly the A. varius, which, although possessing, along with several other species, continued groups of capsules, Will- denow refers to this genus: Probably these may, after all, be Pterides. The A. tetraphylum, A. polium, A. serratodentatum, and A. concinnum, were all found in South America by the indefatigable Himboldt and Bonpland. Besides those species described by Willdenow, the following have been since discovered by Brown.

1. A. paradoxum, with pinnate fronds; the pinnae cordate, oblong, or lanceolate; the veins below obsolete, and the groups of capsules linear and continuous.

2. A. formosum, with fronds decoupled, deltolate, and leaflets tripinnate, with rhomboidal, smooth, and blunt pinnae, the lower ones cut; the involucrum kidney-shaped, and the stipes itself rough, but its ramifications smooth.

Capsules in punctiform or crescent-shaped groups, inserted into the sinus of the scarious involucrum, formed by a portion of the margin folded back, and opening inwards.

The whole of the species have been separated from Adiantum, with which they have the closest affinity; but the interrupted punctiform or crescent-shaped groups of the frond, distinguish them; and, on a closer view, the capsules are seen inserted into the sinus of the involucrum. Of the thirteen species described by Willdenow, there are three remarkable for an agreeable odour:

1. Ch. saxicola, Polypondium saxicola of Desfontaines, with bipinnate smooth fronds, and very entire oblong ovate pinnae, the inferior pinnae pinnatifid, filiform, and hairy stipes. This species is figured by Schkuhr, (Cr. 116, tab. 19.) It is a native of Barbary and Natalia.

2. Ch. odora has also bipinnate fronds, but the pinnae, instead of being perfectly entire, like those of the last, are pinnatifid, with rounded entire borders. The stipes resemble the last. This species is a native of Switzerland and Italy, and ought to be introduced into this country, the climate of which it would endure.

3. Ch. fragrans has also bipinnate fronds, with oblong lanceolate, obtuse, pinnatifid pinnae, and somewhat bifid lacinia; the stipes shiny. The fragrance of these three species renders their culture an object of particular interest, yet the last is the only fragrant species as yet introduced into the collection at Kew by Mr. F. Masson. The Ch. fragrans is figured by Swartz, (Syn.
FILICES.

Fil. tab. 3, fig. 6.) The Ch. pteroides is also in the Kew collection. It is figured by Houttuyn, (p. 120, tab. 16, fig. 3.)

Ch. lentigera, with tripinnate somewhat villous fronds, with minute orbicular folioli, is a singular species. (Comment. Petrop. x. p. 504, tab. 22, fig. 3.) The Ch. arborascens is the only species with an erect stem. This is the Lonchitis tenuifolia of Forster.

(5.) Lonchitis, (Willd. 1777; Schreber, Gen. Plant.1699.)

Capsule in separate crescent-shaped groups, inserted into the sinus of the frond. The involucrum formed by the margin of the frond bent back, and opening inwards.

This genus of Schreber seems to be more conveniently united with the last by a slight alteration of the definition; so that his four species of Lonchitis, added to Cheilanthes, will include, in all, twenty-four kindred species, to which Brown has added, from New Holland.

Ch. caudata, with bipinnate somewhat triangular smooth, pinnaatifid pinnae, and round, lateral lobes. In this species the groups of capsules become confluent, and the involucra obsolete. The figure of Lonchitis hisruta (Willd. Sp. 5.), given by Sprengel (Anell. tab. 4. fig. 27.), affords a good idea of this genus.

Davallia (insulata), (1878, Willd. Sp. Pl. 5.; Smith, Act. Taur. 5. p. 419, tab. 9, fig. 6.)

Capsules in punctiform marginal distinct groups; involucrum superficial, somewhat hooded, opening outwards.

Linnaeus formerly united the various species of this genus with others, to which their external appearance and habit seemed to point. It is a distinct genus, however, as Dr Smith has shown. The groups are situated on the veins or ramifications of the vascular fasciuli, at the margin of the frond. Sprengel has given an excellent figure of the generic character, (Plate IV. fig. 33.) in D. adiantoides, (Willd.) an arborescent species from St. Domingo, figured also by Plumiier, (Fil. 8. tab. 7.)

Willdenow describes 34 species of Davallia, but there is certainly room for a closer examination of these, when it is observed, that Sprengel, whose accuracy is not to be impeached on slight grounds, gives, as an illustration of the genus Adiantum, a figure taken from a species asserted by Swartz and Wildenow to be a Davallia viz. dumosa. The Davallia hisruta (Willd.) is Triehomanes hisruta of Thunberg; and Davallia tenuiflora (Willd.) is Adiantum tenuifolium of Lamarck, (Encycl. 1. p. 43.) It may be further added, that Davallia canariensis is the species which we have selected as illustrative of the structure of the creeping stems of this series. This was the Triehomanes canariensis of the Sp. Pl. (1662) and Brotl. Lindan., p. 395. This species, which is in the Edinburgh collection, has tripinnate fronds alternately decoumpound, with lanceolate sterile laciniae, and obtuse fruitful ones. It is figured by Plukiert (Altn. 156, tab. 291, fig. 2.) It is the only European species as yet known, and found in Portugal and the Canary Islands.

The Us. arborascens of Wildenow, the Filix arborascens adiantoides of Plumiier, (Fil. t. 6.) is found in Hispanicola. It is certainly difficult to devise appropriate specific names for so many plants, which, like the ferns, resemble each other so strongly; but one would have thought the designation arborascens rather un-appropriate, unless, which is impossible, we were certain that no other arborescent species of the genus exist.

ed. This fern has bipinnate fronds; oblong, lanceolate, acuminate, and pinnaatifid pinnae; oblong and bluntly laciniate, and crenate on the superior margin.

The Us. elegans, figured by Schkuhr, (Crypt. 127.) under the name bidentata, is a native of Java, and has also bipinnate fronds; (the undermost pinnae being themselves bipinnate,) with oblong lanceolate, serrated pinnae, wedge-shaped at the base. This species might, from the present connection of Java with this country, have been easily introduced into our home collections.

X. CYATHACEAE. (PLATE CCXLIV. Fig. 20.)

Sir J. Edward Smith, to whom we have had occasion so frequently to refer, first distinguished, from the Polypodium, the genus which we have selected as the type of this singular tribe of ferns. In all the tribes of the series hitherto noticed, the involucrum is superficial, but in this it is formed under the groups of capsules, more or less in the shape of a cup, and in general the capsules are attached to a receptacle, elevated within this cup. The Dicksonia, which we have placed first in this link of the series, has not a distinct receptacle in all the species; but in some the traces of one are perceptible; and we should have erred in excluding it from its kindred genera, although in the Cycads of Smith the character is, no doubt, strongest. But let it be recollected, that the principle of the natural arrangement is essentially different from that of an artificial system, in which all the genera are necessarily distinct, and their characters decided; whereas in the natural series, the groups approach each other by shades, frequently blended, and are abrupt only when the links of the series are either broken or undiscovered, or perhaps lost in the numerous changes the surface of the globe has evidently undergone.

(1.) Dicksonia. (Willd. 1779. I. Heritiier, Sort. An.980.)

Capsules in distinct pointlike, or round marginal groups. Involucrum cup-shaped, double, or as it were bivalve, the true one membranous, originating from a vein, opening outwards; the other spurious, from the reflex-lobule of a pinna.

In this genus then, the cup containing the capsules is formed by the more or less perfect union of the involucra, and within the true involucrum, there is, in some species, a small knob serving the purpose of the columnar receptacle of the other genera of this tribe: Sprengel (Anell. t. iv. fig. 81.) gives a correct idea of this genus in a figure of Dicksonia falcata; the general character of Polypodium, adopted by Linnaeus, including this and several others. Indeed, from the marginal situation of the groups of capsules, this genus externally resembles Davallia; but a careful examination soon points out the difference between them. A figure of Dicksonia falcata (Wildenow and Swartz) is given also by Schkuhr, (T. 129.) This fern is the Triehomanes fuscatus of Forster, (Prodr. 472.) All the genera are foreign, and for the greater part tropical. Several of them have arborescent, or erect stems; although, in order to show the obscurity of such a specific designation, one species only is termed D. arborascens. This species is native of St Helena. It has bipinnate fronds; with ovate, somewhat entire pinnae, with partly united lobes, (Sm. Act. Taur. iv. p. 496.) The D. squarrosa, (Swartz, Syn. 136.) and figured by Schkuhr, is another erect, or arborescent species, (Triehomanes squarrosus, Forst. Prodr. 476.) The D. adiantoides (Humboldt
Capsules in globular, distinct dorsal groups, on the ramification of a vein; sessile and inserted into a common elevated receptacle, situated within the involucrem, which is sometimes multifid, and sometimes obsolete.

Of this genus, which was discovered by Brown in New Holland, there is only one species as yet known, viz. *Alsophila Australis*, with decompound smooth fronds, and bipinnate leaflets, the pinnae attenuated at the point, and the pinnales oblong, somewhat blunt, and serrate in the base; the involucrem nearly divided into two halves. The stem is erect or arborescent, and the fronds firm, and somewhat coriaceous.

Capsules in round groups; involucrem membranous cup-shaped, open, the margin divided into filaments, and including the pedicilated capsules, without any elevated common receptacle.

This genus has an evident affinity with *Alsophila*, in which the margin of the cups is also multifid, although nothing like so finely divided as to have the appearance of hairs. This fine genus still further reduces the number of the genus *Polypodium*; and it is to be hoped, that the excellent observer who discovered it, will continue his invaluable inquiries, into that and others of the present genera, of this great series, following the injunction of our great master—*Texta Naturalis* phyllocharacterem estilato, unde certior eructur generum ordinatio, cum universali tum partiali. (Jussieu, *Gen. Plant. Prod*.)

Some years since Brown observed the cup-like involucrem in *Wood sia* (*Polypodium*, Willd. *Sp. Pl.* 1593, and Sm. *Flor. Britannic.*). *hyperborea*, and he has since repeatedly ascertained it in *Wood sia* *tenuis*. In fact, these two ferns are so very nearly alike, that it is difficult to distinguish them as species. Sir J. Edward Smith describes the *P. tenuis* (With.) and *hyperborea* of Swartz as one species, under the name of *P. arvense*. The stem of this fern is very short, surrounded with the decayed stipules of former years; the fronds are from two to four or five inches long, obtusely lanceolate. The pinnae are distant, lobed, blunt triangular, and sometimes opposite, often alternate, the hairy margin of the involucrem extending over them. This is one of the least of our native ferns. It is found in alpine situations, on Snowden, Benlawers, and others of our mountains.

Capsules in round distinct groups, attached to a hemispherical or club-shaped receptacle contained within the cup-shaped involucrem, which opens above.

In this genus the capsules are attached to a columnar, elevated receptacle, by their pedicles.

Sir J. Edward Smith at first considered three of the former *Polypodium*, viz. the *P. fragile*, *P. regium*, and *P. dentatum* of the Sp. Pl. (1553), as *Cyathia* (see *Flor. Bri*., p. 435); but Swartz and Willdenow, (5, 279-30-81) have arranged these species with *Aspidium*; and in fact, none of the *Cyathia* have as yet been found in Europe. Nearly the whole of the sixteen species described by Willdenow have erect stems. The *C. speciosa*, found by Humboldt and Bonpland, near Carpe in South America, has, like most of the species, the aspect of a palm, being twenty-four feet in height; the fronds finely spreading, and extending five feet around the trunk, and the pinnae petiolated, linear, an inch broad, a foot long, finely pointed, and wedge-shaped at their origin; sinuate, and dentate along their margins. The groups of fruit in this, as in several of the species, are placed sparsely along the margin of the pinnae.

The *C. arboroez* is by no means the most remarkable for the length of its stem, which is very hard, and covered with the scales, so frequently abounding in the whole series. This fern is the *P. arboroez* of *Sp. Pl.* (1554). Rumphius (*Amb. p. 69. t. 27.*) describes other three much akin to this West Indian species. The *C. exselsa*, (Arborea, Bory.) is found in the Mauritius, with a stem twenty-five feet high. The *C. glauca*, is another magnificent fern, found by Bory. (*Itin. 206.*) in the mountains of the Isle de Bourbon. The fronds have not hitherto been brought to Europe; but we may, in some degree, calculate their extent and magnificence (*ex pede Heracleum*) from that of their pinnae, which are, according to Willdenow, eighteen inches long. In this species, the groups of capsules are situated, one on each side of the middle rib of the pinnae. The specific term *glauca*, is derived from the colour of the under part of the pinnae, which, when viewed by the microscope, seems to be owing to the minute scales with which they are covered. Several species, as the *C. aspera* and *C. horrida*, have their stem and stipules covered with hard prickles. The *C. villata*, lately found by Humboldt and Bonpland, is remarkable for having the groups of capsules invested with a woolly covering.

The *Cyathia medullaria* (*Polypodium* of Forster; *Sphenopteris*, Bernh.) is remarkable for the abundance of that saccharine gummy juice which is so common, in greater or less quantity, in the stems of the whole series, and is used as an article of diet by the inhabitants of New Zealand.

Brown has already demonstrated the necessity of separating the *C. multiflora*, Sm. *Horrda*, Sm. *Capsis*, Sm. and others as yet undescribed, from *Cyathia*, under the designation of *Hemidelia*, on account of their arched involucrem, with a semicircular base, inserted under the receptacle.

(5.) *Trichomanes*. (Willd. 1891.)

Capsules marginal, sessile, inserted into a cylindrical common receptacle, contained within a monophyllous pitcher-shaped open involucrem, of a similar texture with the frond.

*Trichomanes brevicutum*, (Br. *Prod*.) *Hymenophyllum alatum*, (Eng. *Bot. 1417*, p. 159.) is the only species native of Britain. As there is already a *Trichomanes alatum* native of the southern mountains of Jamaica, the present specific name has been given to our native fern by Brown. It is the variety (II.) of *Hymenophyllum Tanbridge*. (*Sm. Fl. Brit. 1142.*)

The foreign species *Trichomanes alatum*, described by Willdenow, has pinnate fronds, and the pinnae obovate, acuminate, pinnatifid, and decurrent, with laciniae cut, and dentate, ciliated on the margin, and the stipes alate, or bor-
that of the fronds of the Pinnales, the margin very entire; the under ones bifid; the involucre terminal, with round valves.

The Hymenophyllum, as already observed, have all the habit or external appearance of Trichomanes.

XI. BOTRYCHIACEAE (Plate CCLIV. Figs. 21, 22.)

The Botrychium, which we select as the type of this tribe, forms a link widely detached from the rest of this great series. It is included in the last edition of the Species Plantarum by Willdenow, with the Lygodium, Bernhardina, and Ophioglossum, under Stachyopteris, with neither of which genera in fact it has any affinity whatever, if structure is regarded, as it necessarily must be the only solid basis of a natural arrangement.

In external appearance, indeed, Ophioglossum slightly resembles this genus. The capsules in both are closely situated on spikes, and are globular and unilocular; but in structure they not only differ as genera, but belong to tribes totally distinct; and we shall afterwards be able to show that the Ophioglossum have no relation whatever to ferns, whereas the Botrychium, it is clear, possess considerable affinity with the rest of this series. They have indeed neither rings nor strie on their capsules. The intermediate links of the chain connecting them with the rest of the series are undiscovered, or probably lost; yet certain traces of mutual affinity are, notwithstanding, manifest between them, but accompanied in Botrychium, with marked peculiarities not hitherto observed in any of the known tribes of this extensive series.

The most striking peculiarity in the Botrychium consists in the circinate buds of the future plants being included within a membranous spathe, which bursts as they shoot from the subterraneous stem; whereas in the rest of the series, so far as hitherto observed, the buds are invariably covered with woody scales. We are aware that Swartz has denied that the buds of Botrychium are circinate or involute, in which he has been followed by Sprengel; but having repeatedly dissected them, as represented in Plate CCLIV. Figs. 21, and 22, it is clear, that, in this respect, they nearly approach the rest of the ferns. There is as yet but one genus known, Botrychium. (Swartz, Synops. Fil. 8.)

Capsules in a compound distichous spike, opening in a direction parallel with their insertion.

1. B. lunaria. This is the well known Osmunda lunaria of the Sp. Plant. Lin. p. 1510, and of Hoffman, Germ. 11. 18. and Roth, Germ. 1. and 444. The stipes extending to the length of about five inches, with the frond bluntly pointed, attached towards the middle. The lobes of the pinna are crescent-shaped, nearly sessile, and imbricated, succulent, and of a deep green colour. The fruit-stalk, with its pendulous clustering capsules, rising above the solitary frond, possesses considerable elegance.

2. B. ruvaceum, with the stipes bearing a single bipinnatifid frond, and the laciniæ obtuse, emarginate, bi or tridentate. This is the Osmunda lanceolata of Gmelin, (Nov. Com. Petrop. tab. 11. Fig. 2.) and (Flor. Dantici. t. 18.) It varies with two fronds. It is found in woods in different parts of Europe. The H. maticaroides of the north of Europe, and B. fumaroides of North America, (Wild. Sp. Fil. 5. p. 62 and 63.) are evidently distinct from the two first named species; the fruit-stalk in both being naked.

The remaining six species enumerated by Willdenow, from their evidently different habits, require a closer examination. Whoever consults the accurate
FILGRANE WORK, or FILAGREE WORK, from flium and granaum, is the name given to a kind of ornamental work, in which flowers, &c. are formed of fine gold and silver wire, curled or twisted in a serpentine form, and sometimes plated, and worked through each other, and soldered together.

This art appears to have been brought to Europe from the East, and has been occasionally employed in all ages. Such of our readers as take any interest in the subject, are referred to the following works, quoted by Beekmann in his History of Inventions, vol. ii. p. 245—247.

FILTER, is an apparatus employed to clarify impure water for domestic purposes; and it is also used in many arts, to separate the impurities from other fluids. A filter acts as a sort of sieve or strainer, having innumerable small passages through which the fluid can percolate slowly; but as the passages are not sufficiently large, to allow the particles of matter which are mixed with the fluid to escape, they are detained by the filter.

All springs of water which we are accustomed to call pure, are only rendered so by the effect of natural filtration; for the rain falling upon the surface of the earth, soaks first into the vegetable mould with which the surface is almost everywhere covered; in passing through this, it takes up not only dirt or earthly particles, but the remains of vegetable substances, which are in the progress toward decomposition; the water is thus rendered turbid and unwholesome for domestic purposes: such is the state of the waters of most rivers which are not supplied by springs alone, but by brooks running on the surface. That portion of the water which soaks into the earth having passed through a sufficient thickness of porous strata, either by ascent or descent, will have all extraneous mixtures detained, and become clear spring water. It should be observed, that filtration can only produce transparency, by arresting such particles of matter as are in a state of mechanical mixture with the fluid, for any matter which is held in chemical solution in the fluid will pass with it, through the pores of the most minute filter, unless the substance of the filter itself should have a greater affinity for such matter than the fluid which contained it. In this case, a new combination will be formed, and the matter in solution, leaving the fluid, will be taken up by the filter, not simply because the passages are too small to permit its particles to pass, but on account of the superior elective attraction between the substance of the filter and the dissolved matter.

Filtration, on this principle, cannot continue to produce a natural spring for any great length of time; because, by the constant addition of matter, the filter will at last become saturated with it, or choked up. In applying this reasoning to springs, we shall find a reason why so few springs produce pure water, although it is always transparent. In reality, the great natural filters which produce springs, are almost always on an opposite principle, viz. that the substance which compose the filter has a great affinity for the water, and its particles are thereby taken up slowly in solution, and carried off at the same time that the extraneous matters, which are only in mixture with the water, are detained in the pores of the filtering strata; thus we find few springs which have not some mineral held in solution by the water, although invisible to the eye; and in cases where heat is generated in making the new combination we have spoken of, hot springs will be produced. The most common mineral taint which water receives in its natural filtration, is sulphate of lime or plaster of Paris: this renders the water hard, as it is called, so that it will not produce a lather with soap, but curdles it. Sulphate of iron or vitriol is also frequent in springs. Add to this, that in great towns, the drainage water which soaks into the earth is contaminated by animal matters as well as vegetable, and in such an offensive state, that the filtration through the soil can scarcely restore its purity. From all these causes, it is found that the turbid and foul waters of rivers, where altered by art to separate from their extraneous mixtures, will be more pure and wholesome as a beverage, than the generality of spring water.

Gravel, in thick beds, is the most perfect natural gravel filter; and instances may be met with, of springs from gravel producing water very nearly as pure as distilled water. Sand, when white, such as that of the seashore, is also very good; but if coloured, it generally contains iron; and where the colour is deep, the iron is often in such excess, that it will be communicated to the water in passing through it. Beds of sandstone filter extremely well, and also some porous limestone.

The ordinary filtering apparatus is made from a porous stone, of which there are two kinds; a sandstone procured in Northamptonshire, and a limestone found in Derbyshire. A thick bowl or basin is formed of the stone, and mounted in a frame. The foul water, being poured into the basin, drains slowly through the substance of the stone, and drops into a receptacle below, in a perfectly transparent state. When the water is foul, a small quantity of mud or slime is found to collect at the bottom of the basin, and must occasionally be cleared out; but in the course of time, the more minute impurities will insinuate themselves into the pores of the stone, and at last clog up the passage of the water. This is remedied by chipping away the interior surface of the stone one-half or three-fourths of an inch, because the impurities do not penetrate deeper into the stone; this will restore its action for a long time. We do not approve of the ordinary figure of the filtering stone, which is that of a bowl, because the pressure of the water is unequal in every part; it would be a preferable form to have a vessel of wood, lead, or pottery, and fitted with a bottom, formed from a flat slab of the filtering stone; and this method would admit of constructing a much larger filter than can be done in the form of a basin of solid stone.
The Society of Arts have published a description of a filter by Mr Moul, which consists of a vessel in which the foul water is contained, and a basin of filtering stones being placed in it, the water will percolate through the stone into its cavity, from whence it can be taken up clear and fit for use; or the filtered water may be drawn off, by means of a curved leaden pipe, to reach over the edge of the basin and act as a syphon, with a cock at the lower end. By this plan of filtering the water into the basin, the deposit is not left on the stone, and will therefore be less liable to clog up its pores. The same principle was proposed by Mr Collier; his machine consisted of a cask, or other vessel to contain the foul water. Within this vessel cylindrical tubes of earthenware are fixed; these tubes are closed with a hemispherical end, but the other end, which is open, is applied to the sides of the vessel, and closely fitted there to, so that no water can gain entrance into the vessel, without first penetrating through the substance of the tube. A cock was provided in the side of the vessel, opening within the tube to draw off the pure water. Mr Collier proposed also to fill up the vessel with pieces of broken pottery; which, by presenting a great surface, would allow every facility to the deposition of the gross impurities of the water, and thus avoid the clogging up of the filter, and also render the process more expeditious.

A patent was granted in 1790, to Mr Hempel for a method of making filtering vessels or basins, from a species of pottery, the composition of which was four parts of tobacco pipe clay, mixed up with five of coarse sea, river, or drift sand. For large vessels, this composition is found liable to crack in the burning, equal parts of the clay and sand were therefore recommended; and if this was found insufficient to prevent the tendency to cracking, one-ninth part of Stourbridge clay, or of old crucibles broken down and pounded, was to be added: the basons were turned in a potter's lathe, in the usual manner.

The filtering stones most commonly used are not the best kind, as they are too expensive, liable to be broken, and will not produce so great a quantity of filtered water as others, which, in imitation of the great natural filters, have beds of gravel and sand for the water to pass through. A very simple apparatus for domestic use, consists of a cylindrical vessel of pottery, provided with a cock to draw off the clear water; upon this is fitted another cylindrical vessel, having a globular bottom, which is pierced with small holes; a stratum of coarse gravel is first spread in the vessel, over this a stratum of fine gravel, and above this fine sand. If the bottom of the vessel is covered with a coarse cloth, to keep the sand from running through the holes in the bottom, the gradations of gravel and sand will be rendered less necessary. A plate of earthenware, or a board, is laid upon the sand, and being perforated with holes, allows the water to pass, but prevents the disturbance of the sand when the foul water is poured in upon it, and in percolating through the sand it is filtered. The fineness of the sand and the thickness of the bed will be regulated by experiment; and it is one of the greatest advantages of this construction for a filter, that it can be so readily adapted to the degree of filtration which the water requires, the bed being made thick if the water is very foul, and diminished in proportion to its purity, by which means the greatest quantity of water can be passed through this filter. The sand should be changed every fortnight or three weeks, to keep the apparatus perfectly sweet and clear.

The late ingenious Mr Bramah, had a patent for various modes of conveying and drawing off beer and other liquors, in which he describes a filtering apparatus which he proposed to place in the pipes to conduct the liquor. This was a cylindrical vessel, made of copper, tinmed within, or of any other materials; the upper end was closed by a lid screwed on by a flanach, and the lower end terminated in a cone; a pipe was introduced to the vessel near the lower part to introduce the liquor, and from near the upper end a similar pipe proceeded to convey it away. Between these two was fixed the filtering floor, consisting of flannel, sand in bags, sponges, or other similar substances, which were spread upon a horizontal plate pierced full of small holes, and fixed in the cylinder above the filtering substance; another similar plate was fixed and screwed down to confine it. The liquor was introduced by the lower pipe by means of a pump or otherwise, and ascending through the filtering floor, passed off in a clarified state: the impurities which are separated collect in the conical bottom of the cylindrical vessel, whereas they can be drawn off by a cock. This contrivance is adapted to give a slight filtration to a great quantity of liquor, such as beer.

In 1791, Mr Peacock took out a patent for a method of filtering water in the large way, for the service of towns, &c. His principle was to cause the water to ascend through the filtering medium, instead of descending; and the apparatus, except as to dimensions, very nearly resembled Mr Bramah's, being a vessel divided in two by a horizontal grate or partition, upon which the filtering medium was spread in layers, and the lower division had a communication with a more elevated reservoir, from which the water flowed and rose through the filtering bed. Mr Peacock proposed to use for this, sandy gravel, sand, broken and pulverised glass or pot. ttery, &c. These were to be prepared by repeated washings, and then sorted by sieves into a number of different sizes; these are to be spread in different layers, beginning with the largest and spreading the smaller particles over these, in a regular gradation, until the finest is at the top. This arrangement is better than that we have before spoken of, when the water first passes through the finest, being less liable to choke up.

Professor Parrot of Paris, invented a filter with sand, Syphon acting both by the ascent and descent. It is described filter by in the Philosophical Journal to consist of a bent tube, like an inverted syphon. It is curved to nearly a semicircle; this is filled with sand, and the water being introduced into the longest or upper leg of the tube, filters through the sand, and passes off. At the top of the lowest leg, it is recommended to have three inches of difference between the level of the two surfaces of the water, and eighteen inches of pure sand for the water to pass through. When the section of the tube was four inches by two, that is eight square inches, it would pass six Paris pints of pure water every hour.

Mr John Isaac Hawkins has contrived a filtering apparatus, which we consider as better adapted for domestic purposes than any which we have seen. It consists of a vessel pierced with holes, and placed over another, into which the filtered water is to be received. A layer of pounded charcoal is spread in the bottom for the water to filter through; the lowest part of the layer is to be composed of charcoal, pounded as fine as coarse sand; and above this, other pieces increasing in size, till the largest, which are as large as pease; the whole is covered with a board pierced with holes to admit the passage of the water, but, at the same time, to prevent the
charcoal being disturbed when the water is poured in. Another form of the apparatus is very well adapted for the use of a ship's company. It consists of a cask divided by a vertical partition, which does not quite reach the bottom, but leaves a space for the passage of the water. The bottom of the cask is filled with powdered charcoal, so as to reach some inches above the space at the bottom of the partition. The foul water being poured into one of the divisions of this cask, is filtered in passing to the other, by being obliged to descend through the charcoal on one side, and ascend through the other. This machine affords a great quantity of water; and the known antisepctic quality of the charcoal is of great consequence in removing any taint with which water is often affected, and which is not easily removed by any other filter, unless indeed it is made very fine, such as a thick filtering-stone, and this will permit the water to pass but very slowly.

The most simple filter for experimental inquiries is made by a piece of blotting paper, rolled up to form a conical funnel, and twisted tight at the point, so that the fluid cannot pass, except through the pores of the paper. This funnel is to be placed in the neck of a wide-mouthed bottle, and filled with the liquor, which will filter through the paper, and drop slowly from the point of the cone in a very pure state.

Another method, which is still more delicate, is performed by capillary attraction as well as filtration. For this purpose, a glass is filled with the fluid nearly to the brim, and a bunch of coarse cotton threads, such as are used for the wicks of lamps and candles, is hung over the edge, so that one end of the bunch is immersed in the liquor, and the other hangs over a small bottle or other vessel destined to receive the clear fluid. In this way it will be drawn up on one side, and conveyed through the cotton, from the ends of which it will drip very slowly, but in a most perfect state of purity from all extraneous mixtures. It is scarcely necessary to mention, that the cotton must be wetted with the liquor, or the ascent will not begin when it is first put in action. A piece of thick flannel, if it is doubled three or four times, will answer the same purpose particularly well.

A very ingenious filtering apparatus has recently been invented by Mr. James Innes of Edinburgh. A piece of wood is placed within a cylinder, containing the wood, which is forced through the pores of the wood by the pressure of a forcing-pump. Mr. Innes has employed this simple machine for purifying oil and other fluids.

FINEERING. See Veneering.
FINGER-KEYED INSTRUMENTS, in Music, are in general such as are performed upon by touching with the fingers a system of levers, called keys, manual keys, or the clavier. The organ, virginal, spinet, harpsichord, piano forte, and barillons or carillons, are well known in this class of instruments. Mr. John Isaac Hawkins, a few years ago, invented a new instrument, consisting of a rotative bow of horse hair, that could be made to act at pleasure upon catgut strings, which he designated a Finger-keyed vial or clavele. M. Chladni likewise invented a new instrument, called a Keyed Cylinder. See the Monthly Magazine, vol. xxvi. p. 514.

The ordinary form and arrangement of Finger-keys are found well adapted to the diatonic scale, or in which five notes and two half notes are comprised in the octave, two whole notes or long keys being associated together, and three such, with a half tone between each of these groups, which are separately called a ditone, and a tritone by Dr. Calcott. In the former of these groups, two shorter keys of a different colour (now usually black, the long keys being white,) are inserted between the long ones; and, in the tritone, two such short keys are interposed, by which the whole douzeve, or range of 12 half notes in the octave, is completed, and every other octave, above and below, is but a repetition of the first.

The most conspicuous and best marked finger key in the arrangement above described, is the long one in the middle of the ditone, which belongs to the letter D, which is the second of the natural key; beginning therefore at C, the letters belonging to each of the finger keys are as follows: viz.

Ditone. Tritone.
C D E F G A B C

Although three of the short notes above are described as sharps, and two of them as flats, yet common instruments are obliged to be so tuned, that every short note may indiscriminately serve either for the sharp of that on its left hand, or for the flat of that on its right; and even so that E and F, and B and C, may also serve as the flats or sharps of each other respectively.

This very confined nature of the key-board, or system of finger-keys, long presented a serious bar to improvement in the tune of these instruments with fixed tones, until at length Mr. Hawkes produced his patent instruments, on which all the five short notes might be tuned to sharps, and, by means of a pedal, the connection of the keys with these strings or pipes might be instantly loosed, and the same short keys be made to act on another set of those tuned to flats, thereby introducing 17 sounds in the octave, but with the disadvantage of being unable to use a flat of any one note and a sharp of another at the same time. But these and other defects the patent instruments of M. Leeschman and of Mr. Liston now remedy, by means of several pedals, adapted to take away two sharps at a time at one end of the scale, (See our article Succession of Fifths,) and to supply to the same finger-keys two flats in the place of them, in the order of modulation: thus, for instance, out of the original scale that we have represented above, the first flat pedal will remove G⁸ and C⁸, and supply in their places A⁷ and D⁸; the first sharp pedal will remove E⁷ and B⁷, and replace their connection with the short finger-keys, by D⁸ and A⁸, and so on, leaving the performer all the present uses of the finger-keys, except during the instants when the pedals are in motion.

However perfect and easy the use of the present key-board may seem to practised musicians without the pedals above mentioned, a desire has long existed for simplifying it for the use of children and beginners.
This the late Mr Charles Clagett attempted by his equal 
keys; and more recently Mr Trotter took out a patent 
for a key-board, better adapted to the use of beginners, 
and for transposing or playing music in a different key 
from that in which it may be written. See the details 
of this latter invention in the *Repertoire*, vol. xxii. p. 
197. (2)

**Finger-key Intervals**, in Music, or degrees of the 
state or scale, are very commonly denominated half- 
notes, half-tones or semitones, and considered as equal 
among themselves 1 as though the Isotonic system was 
alone in use, notwithstanding the high probability, 
which has often been mentioned, that an equal tempera-
ment has never yet been heard on the organ, rarely so 
or very near it) on the piano-forte; and it is certain 
that this system never was, or will be, performed by the 
voice or violin. It is, however, of considerable use to 
the musical student, to be able to class the great number of 
musical intervals which present themselves according 
to the finger-key of his organ to which they severally 
belong, and by which they can alone be brought into 
use on that instrument, while the key-board remains li-
mitcd as at present. Fortunately, the new notation 
which we use, enables us to make this classification 
without any trouble, because every interval, regularly 
expressed in Farey’s *Notation*. (See that article), has 
The f’s therein equal to its number of finger-key inter-
vals, artificial half notes, or chromatic semitones of Cal-
cott, as the following table will fully explain, viz.

This Table has three columns, numbered at the top 
and titled at the bottom, the first of which shews the 
number of f’s, in the least interval that has 1, 2, 3, &c. 
f’s respectively, in col. 2; or, such f’s in col. 1 may 
be considered as the limits between the different finger-
keys numbered 1, 2, 3, &c. in col. 2. In col. 2, some-
times 3 and sometimes 4 intervals, numerically expressed 
with the addition of b’s and %’s, are set down as be-
longing to each finger-key; such pairs of these inter-
vals as are linked together, are of equal value, respec-
tively, in Mr Liston’s enharmonic scale. Each of the 
finger-keys on Mr Liston’s organ, yield occasionally 
five different sounds, except the ninth, or A key, which 
produces only four sounds, making in all 59 sounds in 
the octave. (c)

**Finland**, a division of Sweden, but recently an-
nexed to Russia, is situated between 60° and 66° 23’ 
North Latitude, and between 21° 20’ and 31° 20’ East 
Longitude from Greenwich. It is bounded on the north 
by Swedish Lapland; on the west by the Gulf of Both-
nia; on the south by the Gulf of Finland; and on the 
est by the Russian territories. It is divided into se-
divisions, or provinces; namely, the Aland Islands, 
Finland Proper, East Bothnia, Tavartland, Nyland, Sawola, 
and Keymenegur. The Aland or Oeland Islands, 
about 80 in number, and generally small, are situated 
at the mouth of the Bothnian Gulf, between Upland 
and Finland Proper, and in 1792 contained 11,960 inhabi-
tants. The largest, named Aland, is about 14 leagues 
in length, and five in breadth; and its principal town, 
Castleholm, is remarkable only for its ancient fortress, 
where the unfortunate Eric XIV. was imprisoned in 
1571. The inhabitants of these islands, who appear to 
have been originally Laplanders and Finns, live to a very 
great age; and about 250 of them are registered as sail-
ors, whose pay from the government amounts to about 
5000 rixdollars yearly. In most of these islands, though 
included in the government of Finland, the Swedish 
language is spoken by the people; and the Finnish 
tongue begins to be heard only in Helsing.

Finland Proper, the southwest province, extends Finland 
about 60 leagues from north to south, and between 25 Proper. 
and 33 from west to east. It is agreeably diversified 
with lakes, rivers, woods, arable fields, and pasture 
grounds; and, though inadequately cultivated, is toler-
ably fertile. Its towns, which are all situated on the 
coast, are, Abo, the capital of the province, a bishop’s 
see, and the seat of a university, about 41 Swedish miles 
N. E. of Stockholm, and containing about 9750 inhabi-
tants; Nystadt, a small trading town with a good 
port, north of Abo; and surrounded by a pleasant tract 
of country; Borrieberg, an ancient but insignificant 
sea-port; and Nadenhal, a little town to the north of 
Abo.

East Bothnia, or Cajania, extends along the gulf of East Both-
that name to the northern extremity of Finland, and is nia- 
upwards of 100 leagues in length, and between 30 and 
70 in breadth. The country on the coast is level and 
marshy, and a ridge of hills runs along the south and 
est boundaries of the province. The towns, as you 
proceed northwards, are, Christinastadt, a small place 
near the south border, with a harbour of difficult en-
tance; Wasa, a sea-port town, rapidly increasing in 
trade, provided with a tribunal of justice for the north 
of Finland, and containing, in 1790, about 4000 inhabi-
tants; Gamla Carleby, a small but regular town, 
about 34 leagues S. W. of Uleborg, situated in a sandy 
and marshy country, and containing about 1400 inhabi-
tants; Brakestad, a small sea-port, which carries 
on some trade, contains about 800 people, and is about 
20 leagues north of the last mentioned place; and Ulen-
Nyland stretches along the north coast of the Gulf of Finland about 40 leagues, and is between 15 and 18 in breadth from north to south. It is level, fertile, and in some parts tolerably cultivated. Its towns are, Ekenas, a small sea-port, about 50 miles south-east of Abo; Helsingfors, the capital of the province, provided with a good harbour, and defended by an immense fortress, called Swesi Borge, standing on a rocky island at the entrance of the port, capable of containing 7000 men, and designed as a bulwark against the encroachments of the Russians; Borgo, a small but ancient town, about 10 leagues eastward of the last mentioned, pleasantly situated on a hill, and containing a university, or rather academy, taught by seven professors; Lovisa, or Degerby, formerly the frontier town between Russia and Finland, built in the midst of a remarkably stony or rather rocky country, but provided with a very convenient harbour.

Sawolax, an inland province to the north of Nyland, extends about 70 leagues from north to south along the confines of Russia, and about 30 from west to east. It is covered with forests, rivers and lakes. The lake of Saima, which is nearly 160 miles in length, and 25 at its greatest breadth, lies partly in this province, and partly within the Russian territories, and has a communication with lake Ladoga by means of the rapid river Voxen. Its principal town, Nylot, is situated near the south border.

Keymenegard, which lies on the south-east extremity of Finland, is naturally fertile, but thinly inhabited, and almost destitute of cultivation. Its chief town is Kuopia; but the districts of Carelia and Kexholme, once belonging to this province, have long been included in Russian Finland.

Russian Finland, forming the province of Wybourg, was ceded by Sweden, partly in 1721, at the peace of Nystadt, and partly in 1741, by the treaty of Abo; and contains six districts—Wybourg, Frederiksham, Wilmanstrand, Nylot, Kexholme, and Sardobel. The whole of Finland, indeed, is now to be included by the geographer, within the wide extent of the Russian empire. After having been the scene of many bloody struggles between the Swedes and Russians, it was completely overrun by the latter power in 1808, and soon after formally ceded by treaty. It was lost by the folly and incapacity of the late monarch of Sweden, who left its brave defenders to sink under an overwhelming force, while he was vainly intent upon the reduction of Norway and of the Danish islands in the Baltic.

Finland contains about 48,780 square miles, and 700,000 inhabitants. It is covered with numerous lakes, which give rise to several rivers, generally rapid, but soon reaching the end of their course. The chief of these are the Ulea at Uleaborg, which is navigated by trading vessels, though its stream is so rapid, that the ships run down the river at the rate of 18 English miles in the hour; the Cano, which passes Bjornetveit; the Aurajoki at Abo, about 100 yards broad, and remarkable for its muddy waters; the Kymen, which flows into the middle of the Gulf of Finland, and forms the boundary between Swedish and Russian Finland.

The mountains of Finland often contain a brown mixture of felspar and mica. Lead ore is found in various parts, and a ferruginous earth from which iron is extracted. There are, in many places, very extensive forests, and one particularly to the north of Abo, about 80 miles in length. Great devastations are occasioned in these forests by the tempests of winter, which seem to find access to the very centre of the wood, by descending in the manner of a tornado, and which tear up by the roots, or break in the middle of the trunk, or bend to the earth, the most enormous pines. Frequently also similar rages are committed by conflagrations, occasioned by the carelessness of the peasants in smoking their pipes and making fires in the woods; and sometimes, it is suspected, intentionally kindled, from an interested motive, as the inhabitants are allowed to cut down, for their own use, any trees in the king's forests, which have been injured by the burning,
Finland.

The Finnish language abounds in proverbs, bearing much resemblance in their form to those of Solomon, and generally expressive of sound sense and acute remark. They are mostly in Runic or alliterative verse, and divided into two hemistichs, the latter of which contains an illustration of the former. A good man averted from him, but the wicked will not give from a bushel. "'The wise man knoweth what he shall do, but fools try every thing."—"The work is ended which is begun; there is time lost to say ' what shall I do?'"—"The tools of the industrious man is sharp, but the plough-share of the fool wanteth grinding."

The inhabitants of Finland are not less sensible to the influence of music; but, owing probably to the imperfection of their national instrument, they have not made much progress in the art. Their native instrument, the harpp, consists of five strings or chords of metal, each of which sounds a distinct note, a, b, c, d, e, and within the compass of these five notes, the whole of their music is confined. But the violin has been introduced in later times; and the music of the Finlanders is beginning to acquire a more varied character.

Their dancing consists in the most rustic jumping, without any variety of step or motion, except alternately laying the arms over each other; and the whole exercise is performed with sufficient vigour, but with entire gravity, and most unexpressive countenances.

The houses in Finland, and frequently even the Houses, churches and other public edifices, are constructed of wood, generally painted red; but they are nevertheless sufficiently warm, and sometimes too much so for the feelings of those who are not accustomed to a close atmosphere. The habitations of the peasants are well built, and afford complete protection from the severity of the winter cold; and, notwithstanding the long duration of that season, and the seeming sterility of the soil, the people are in many respects better provided than the same class in more southern regions. They can generally set before the traveller at least fresh and curdled milk, salt herrings, or a little salt meat; and they are rich in all that they consider as constituting the enjoyments of life. If at any time they have more money than their immediate wants require, they either lay it up for future emergencies, or convert it into some domestic utensil; and it is not uncommon in a small wooden dwelling, to see the water presented in a silver vessel of the value of 50 or 60 rixdollars. The women are warmly clothed, and above their other garments wear a large linen shift, which gives them the appearance of being in an undress. In the house, the men generally throw off their coat, and even in that manner perform their ordinary labours in the open air; but when they go out to a greater distance in the winter season, they wear a kind of short coat made of calf-skin, or a woollen surcoat, fastened round the middle with a girdle; and pull over their boots coarse woollen stockings, both for warmth and for safer walking on mountainous ground. Most of the peasants have a small house for the purpose of taking the warm bath, which is done in the following manner. A number of stones in the innermost part of the chamber are heated by fire till they become red; and water being thrown upon them in this state, the bathers are involved in a cloud of thick vapour, in an atmosphere of 70 or 75 degrees of Celsius. In this heated and oppressive air, they remain naked for the space of half an hour or even a whole hour, rubbing their bodies, or lashing them with bunches of

The Finns appear to have been the original inhabitants of Sweden, and to have proceeded from their settlements around the White Sea, a country formerly styled Permia, or Blarmania, and still exhibiting remains of their ancient prosperity. They are short in stature, with flat faces, dark grey eyes, a thin beard, tawny hair, and a sallow complexion; but those who inhabit the more southern and western districts of Finland, while they retain the national features, have a superior appearance, and are scarcely to be distinguished in their manners from the Swedes. In Russian Finland, however, they have a slowness of motion, a depression of spirits, a simplicity, and almost stupidity of look, which form a striking contrast with the lively aspect, alert movements, and cheerful humour of the Russians; but these circumstances may be chiefly owing to their condition as a conquered people, imitating and dreading their masters. More hardly than the Muscovites, they are not so warmly clothed, and seldom wear the sheep skin; but have a coat of coarse woollen stuff, made without regard to shape, and tied round the body with a band, a pair of coarse linen drawers, or loose pantaloons, straw shoes, and pieces of woollen cloth, or ropes of straw wrapped round their legs.

It is chiefly in the northern parts of Finland, or rather in Lapland, that the ancient Finnish language is heard. Along the gulf of Finland and Bothnia, the Swedish language prevails in the towns; and the peasantry speak a mixed dialect of both tongues. The Finns were subdued by Eric IX. King of Sweden, and converted to the Christian faith in 1156; and from that period, literature, especially poetry, began to be more generally cultivated among them. The verse which they employ is called Runic, in which the lines consist of eight syllables, a long and a short in succession; but, instead of terminating in rhymes, they begin with alliteration, having at least two or more words which agree in the same letter or sound, as in the following specimen:

Nuo nuco pico linto
West vel ester eki.

These Runic verses are rarely committed to the press, or even to writing, but are chiefly transmitted by oral communication; and none are found of an earlier date than the era of the Reformation.

In the more inland districts, the peasantry are much addicted to this species of composition; and many of them, unaided by education, are capable of producing these verses on ordinary subjects, sometimes in a great measure extemporise. The recitation or composition of such songs, sometimes accompanied with the harp, forms one of the most frequent amusements of the country people at fairs and private meetings. On these occasions, the reciter or poet stands in the midst of a circle of auditors, and having sung or delivered one line, a conductor, taking up the last word, or the last but one, finishes the line along with him, and then repeats it alone, which gives the speaker time to recollect or compose the succeeding line, which he then sings, and his assistant repeats in like manner, until the poem is ended.

twigs; and frequently go out without any covering to the open air, or even roll themselves in the snow, when the degree of cold is 20° or 30° below zero; thus making an instantaneous transition of 100 degrees, which is almost equivalent to passage from boiling to freezing water. This practice, they affirm, has a most invigorating effect upon their frames, and recruits their strength as much as rest or sleep.

The Finnish peasantry are at all seasons busily employed in active labour; and even in the depth of winter find abundance of employment both in the house and abroad. Within, they are engaged in making nets, constructing cart wheels, forming faggots for fuel, or threshing their corn; and out of doors, they cut down timber, and easily drag over the ice or snow such enormous trunks as they could scarcely be able to move in summer. Fishing and hunting may be considered as their necessary avocations, rather than voluntary amusements. In fishing with hooks, they scour over the ice in long wooden patterns, pushing themselves along with incredible velocity, by means of a pole which they hold in their hands; and when they have reached the place where they intend to fish, they spread a triangular sail to shelter them from the wind, perforate the ice with a chissel, plunge their line into the sea to the depth of about 30 feet, and are sometimes obliged to continue stirring the surface of the water to prevent it from freezing. In fishing with nets, they make two openings in the ice, and by means of ropes and long poles pass the nets from the one to the other, which they afterwards draw out with great labour. In autumn, when the frost begins to set in, and the ice is most transparent, the fishermen course along the rivers with a wooden club or mallet in his hand; and when he observes a fish under the ice in shallow water, he strikes a violent blow perpendicularly above it, which at once breaks the ice and stuns the fish, so that he easily seizes it with an instrument made for the purpose. In hunting the seals, they take post in the neighbourhood of their haunts, behind a mass of ice, and wait till one of them comes out of the water. It frequently happens, that the hole in the ice by which he ascends is frozen over almost instantaneously; and the hunters then fall upon him, before he has time to make a new aperture with his breath, or at least before he can reach the opening, should it still be passable. In these extremities the animal makes a desperate resistance, seizing the clubs with his teeth, and attempting to reach the assailant; but the slowness of his motions renders his efforts unavailing, and he is soon dispatched without much rile. The Finlanders' mode of hunting the bear requires a greater degree of intrepidity and presence of mind. Instead of a musket, which might be injured by the damp, and prove a very uncertain weapon, the hunter uses an iron lance fixed at the end of a pole, and having a cross bar about a foot distant from the point. When the bear has been irritated to rush from his den, and is rearing himself on his hind legs to seize his daring antagonist, the peasant drawing back the iron lance close to his breast, so as to conceal the length of his weapon, and render the animal less watchful against its stroke, advances boldly within arm's length of the bear, and plunges the point into his heart. The cross bar prevents the lance from passing through the body, keeps the animal from reaching the hunter with his paws, and serves to throw him on his back, while the wounded bear hastens his own death by holding the weapon fast, and pressing it more deeply into the wound. A still more hazardous enterprise is the seal hunting in the spring, after the frozen sea breaks up, and the ice floats in shoals upon the surface. Four or five persons set sail in an open boat with one small mast; and expose themselves during the space of a month or more, and in the most unfavourable circumstances, to all the dangers of the ocean. In the pursuit their little bark is continually placed between masses of ice, which threaten to crush it to pieces; and in order to reach the seals, they must crawl along the floating shoals, killing them as they repose upon the ice. During the same season they hunt the squirrel, which they kill with a blunt wooden arrow, shot from a cross-bow, that they may not injure the skin. The bow used in this sport, is of a very ancient construction, extremely heavy, and requiring great strength to bend it, even with the assistance of a thong. The peasantry are remarkably dexterous both in the use of this bow and of the fowling-piece, loading the latter always with ball, and rarely missing the smallest bird. They employ for this purpose a kind of rifle gun with a narrow bore, which requires but a very small charge, and yet carries to a considerable distance. The winter also is the principal season of traffic; and all the great fairs are held in Finland and Sweden in that time of the year, in consequence of the facility of carrying goods over the ice, and travelling in sledges on the snow. The peasants on these occasions frequently undertake journeys of three or four hundred English miles, carrying with them whatever articles they have for sale. In Finland, the sledges are very narrow, containing only one person, and drawn by a single horse; and the roads are deep ruts formed by the successive passage of these vehicles, thus admitting none of a larger size than what are generally used in the country. The circumstance of being overturned is rarely productive of any serious consequences; and the dangers attending the traveller arise chiefly from those parts of the rivers or lakes where the ice is insufficient to support the weight. Excepting the bear, which rarely comes from his den to attack the inhabitants, until he is first provoked, the only other savage creatures in the country are wolves; and those, even when starving, will not venture singly to assail the passenger. When assembled, however, in herds, and impelled by famine, they sometimes rush upon the horses in the sledges; and should the traveller be overturned and left upon the road, he must fall a prey to their ferocity.

Many strange and sometimes indelicate customs prevail among the inhabitants, some of which will come more properly to be noticed under Sweden, as being common to both countries, and others of them under Lapland, where these ancient peculiarities have suffered least change. A Finnlander, when about to form a matrimonial connection, commissions some old women to make known his proposals to the object of his affections; at the same time sending a present of a handkerchief, riband, or piece of money. The messenger waits upon the young woman while undressing at night, and after dwelling on the praise of the lover, slips his gift into the fair one's bosom. If the present is retained, the young people consider themselves as mutually engaged, and nothing but the marriage ceremony is wanting. But if the present be returned, this indicates a refusal, which may nevertheless yield to a second proposal, unless the young woman, instead of returning the gift with her hands, suffers it to drop to the ground, which is counted a positive token of decided rejection. At the marriage, one of the friends or neighbours, with the orator or speaker, does the honours of the feast, who generally also recites verses, or makes them extemporary suitable to the occasion; and, on the day following, after addressing some advice to the married...
FIRE-ESCAPES.

couple, he strikes the woman repeatedly round the body with the husband's breeches, commanding her to be fruitful, and to furnish him with heirs of his own body. In some places, a practice resembling the "burning of the Americans," is said to exist. Both in the towns, and among the peasantry of Finland, a stranger experiences the utmost kindness and hospitality. He is always treated as the first person in the company; and every endeavour is made to consult his taste and gratify his feelings. Even among the principal inhabitants of the towns, a stranger and rather startling mode of satisfying satisfaction with a visitor, is practised by the ladies, who, as soon as the entertainment is concluded, give him a slap upon the back when he is least expecting it; and the more forcible the application of the hand, the stronger is the declaration of good will. The peasants display great disinterestedness in their services to strangers, and can seldom be induced, without considerable importance, to accept a pecuniary remuneration for any occasional assistance, which they may have rendered. See Coxe's Travels in Russia, &c.; Acerbi's Travels in Sweden, &c.; Wraxall's Tour round the Baltic; Swinton's Travels into Norway, &c.; Clarke's Travels, vol. i. 9)

FIRE-ESCAPES, are machines for enabling persons to descend from the windows of a house when it is on fire, and when the stair-case and passages are so filled with the flame or smoke, as to prevent a retreat by the ordinary avenues: Some of these machines are contrived to convey down valuable goods as well as people.

A person who is awakened from a profound sleep by the flames of a fire, which has already made such progress as to cut off all retreat, has no other alternative than leaping from a window, perhaps of great height, or perishing by the flames. This is a situation so dreadful, as to demand every exertion of ingenuity, and every regulation of the police, which can contribute to the relief of the sufferer. Frequently as this tragedy is repeated in London, every new instance makes a lively impression on the public mind, and rarely fails to give rise to the invention of some new fire-escape; yet still we do not find any of these adopted so generally, as to remedy the evil. This may be owing, either to the inefficiency of the contrivances, or to the neglect of the magistracy to provide a proper number.

Machines for this purpose are of two different kinds, first, those which are intended to operate from the street below, and can be quickly erected to communicate with any window: Of this kind are ladders, and poles with pulleys and ropes to draw up a basket, also a variety of curious and complicated machines or elevators; of course all such machines must be kept at the public expense, for the service of a whole parish, in the same manner as fire-engines, and must be made to remove very readily. The other kinds of fire-escapes are those which can be fixed to a window, and allow the unfortunate sufferer to descend safely into the street. Machines of this kind are intended to be kept in the bed-rooms of the house; and each house must be provided with one at least, to render the contrivance generally effective. Both kinds have their inconveniences; the first, from the difficulty of conveying them with dispatch from the places where they are deposited, to the situation where they are to act; this objection they have in common with fire-engines; but it is here more sensibly felt, because the fire-escapes which have been made, are but very few in number; nor can it indeed be expected that they will be generally provided, unless parishes were obliged by law to keep fire-escapes as well as fire-engines, and in this case the same regulations might be applied to both.

At present in London, and some other large towns, fire-lad- ladders are kept in every church-yard, for the service of any fire which may happen within a reasonable distance. This regulation is in a great measure rendered useless from inattention in the keeping of the keys of the locks, which are applied to prevent the ladders from being improperly removed. A key is generally deposited with each churchwarden, and one with the clerk of the parish, but the nearest watchman, or every patroller, should be provided with a key, that no delay may occur in rendering assistance. A melancholy instance of the necessity of this regulation occurred in London a few years ago, when three persons were burned, at the windows of a house, from which they had a sight of the fire-ladders, but the churchwarden, who lived at some distance, could not be awakened to procure the key until too late.

We have seen, some years ago, a long ladder, provided with a pair of wheels, which were fitted upon an axletree attached to the lower end of the ladder, within about three feet of the extremity. A weight was attached to the end of the ladder, to counterbalance so much of its weight, that one man, by treading upon the lower end, could elevate it upon the axle of the wheels; but when raised to about an angle of 65 degrees, the end of the ladder touched the ground, and therefore if it was elevated more than that, the wheels were born off the ground, and left the ladder to support itself independent of them.

This simple addition of wheels to a fire-ladder is of great advantage, not less in conveying it to the place, than in raising it, which is always a work of much labour, and among those who are unused to it, of no small difficulty. With the wheels, nothing is more easy, the weight being balanced, and three or four men can draw it along the streets as quick as they can run, whereas, at the utmost, they can only walk quickly when bearing a long ladder on their shoulders, from the difficulty of stepping exactly equal paces. The length of the ladder should be from 25 to 30 feet, according to the kinds of houses in the neighbourhood where it is to be kept. This simple contrivance appears to us of more utility than any other fire-escape which we have seen proposed. Amidst the number of ingenious, but complicated machines, which have been rewarded and published by different learned societies, we have no doubt that a sufficient number of fire-ladders, thus mounted, and kept as the ladders now are in the church-yards, would be the most effective provision that could be made against accidents of this nature. As we are not altogether with the hope of seeing this arrangement adopted, we shall add a few words on the best and most economical method of constructing such machine; because when great numbers are required, the expense is an object of attention. The two spars of the ladder may be formed out of a clean piece of fir, such as is used for masts and oars. Each should be about five inches by three at the lower end, and regularly tapering up to three by two at the other; now, as the spars are much weakened by the holes bored through them, for the rounds or steps, we propose to use another method, and at the same time to truss the spars, to render them more strong. For this purpose, each is to be divided from the middle to within three or four feet of each of its ends, by a saw-kerf, made in the direc-
FIRE-ESCAPES.

FIRE-ESCAPES.

tion of the length of the piece; a wedge is then to be driven into the cleft, to open it in the middle, to a width of eight inches, and small blocks of wood are to be fitted into the opening, which will be eight inches wide in the middle, and gradually diminishing to nothing towards the ends, where the spars have not been divided. One of these blocks should be placed at the proper place for every round or step which is intended to be made in the ladder; and the ends of the rounds are to be fixed in these pieces, except towards the ends, where the cleft being narrow, the ends of the rounds themselves being made square, may be fitted in the opening instead of the blocks. The blocks and the ends of the rounds, where they touch the insides of the opening, should be let into the wood the eighth of an inch to prevent them from moving. The whole is to be bound fast by slight iron hoops, driven on from the ends, and particularly at the solid ends, to prevent the opening splitting farther than was intended. By this method a ladder is formed of very great strength, without increasing the weight. It is the same mode of strengthening spars, which has been proposed by Mr. G. Smart, for temporary yards for ships. The wheels of the ladder should be of the largest size used for phaetons, which is about five feet eight inches, with twelve spokes. It is an advantage to have the wheels as large as possible, because a smaller balance weight will then be sufficient. The weight should be of cast iron, and fixed across between the two spars, in the manner of a crossrail at the extreme end, so that it will be as far as possible removed from the axle.

From a machine of this kind we may expect all that can be done by a simple ladder; but by the addition of a rope, pulley, and basket, it may be made capable of lowering goods, or helpless and infant persons, and children. The pulley should be suspended from a round, at about three feet from the upper end, which round must in that case be made of iron. The rope should be rather more than twice as long as the ladder, and of a sufficient strength to bear four hundred weight. The basket should be very shallow, and surrounded by a strong sack-cloth, so as to be rather a sack with a basket bottom, and a hoop in the mouth to keep it extended; this will fold, and lie close to the underside of the ladder, where it should always be lashed by the spare end of the rope, the remainder being extended between the pulley and the lower end of the ladder, so as to be in no danger of entanglement. In this way, the operation of the ladder will not be at all impeded, and the rope will always be ready for action, by uniting the end of the rope, and thus releasing the basket. This rope will be extremely useful to haul up the leathern pipe or hose of an engine; and the fireman ascending the ladder, will be able to direct the jet to the upper part of the structure, without danger of being exposed. If the rope is not of sufficient length, or if the first, second, third or fourth, the rope sustaining the weight of the pipe, which would otherwise be too great for one man to hold when upon the ladder.

A machine is described in the Annual Register, some years ago, with a rope and basket; but a pole from 36 to 46 feet in length was used in place of the ladder. This pole had the pulley fitted into a mortise, at three feet from the upper end; it had also at each end an iron cross bar fixed, to project perpendicularly on each side, one to bear against the wall, and the other upon the ground, and form a foot to keep the pole steady. To assist in raising the pole, two smaller poles or handles were connected with the great one, at two or three feet above its middle, by eyes which admitted a motion in every direction. Several persons could apply their force very advantageously at the ends of these poles, to elevate the great one; and when it was raised, the poles formed legs like a tripod, to strengthen the great pole, and prevent it from bending in the middle. It is stated that a pole of this sort was elevated, and two or three persons lowered from the upper windows of a house, into the street, in the space of 35 seconds, or rather more than half a minute. Still, as the pole was five inches diameter at the base, and three at the upper end, it could not, with the addition of the side poles and basket, be rendered very portable, and, from its length, would be troublesome to turn the angles of narrow streets, and therefore we prefer the ladder with wheels, which is extremely easy of transportation, and which, from the facility of raising it by the balance weight, can be elevated to turn a narrow corner. If it is trusted, as we have described, it will have as much strength as the pole, when propped in the middle by the two short ones.

We think it is scarcely necessary to describe any other machines, except very briefly. The principle of several of them is to have two, three, or four ladders, fitted one upon the other, or rather one within the other, and provided with a tackle by which they can be elevated to the height of the window. The most complete of this kind is described by the Society of Arts, in their Transactions, vol. xxviii. The base of the machine is a four-wheeled carriage, with a pair of shafts for a horse to draw it. The lowest of the three ladders is fitted in the carriage by a bolt, on which it can be inclined side-wise at pleasure, to reach the window, and retained at any elevation by a frame with screws. The three ladders are made to fit one within another, and provided with iron clamps to connect them together. In the back of the frame, beneath the ladder, is a windlass, which receives the ropes for sliding up the ladders. These consist of two parallel ropes, proceeding from the windlass, and passing over two pulleys, fixed at the upper end of the principal or lowest ladder, and the ends are made fast to the bottom of the second ladder. Therefore, by turning the windlass, the ropes are drawn, and the second ladder is elevated upon the first. The third ladder is likewise provided with two parallel ropes, passing over pulleys, at the top of the second ladder, and attached to the bottom of the third; but the opposite ends of these ropes, instead of being carried down to the windlass, are made fast to any part of the lower ladder: in this way they have the same effect to raise up the third upon the second, when that is elevated upon the first by means of the windlass. The remainder of the apparatus is a windlass, in front of the machine, with two ropes passing over pulleys at the top of the highest ladder, and suspending a box or chest, in which the goods are to be lowered down. The upper end of the ladder is provided with a bent iron bar, to lean against the window, and thus retain the top of the ladder at such a distance from the wall, as to admit the box to ascend and descend clear of it.

We have seen another machine on a different principle: its carriage supported an upright post, which was fitted to turn round in the manner of an axis. The top of it formed the fulcrum of a very long lever, which, at one end supported the basket, and at the other a considerable balance-weight. The height of the vertical pillar was such as to raise up the centre of the lever to about half the height from which the descent was intended to be made. The lever then required to be sufficiently long to reach to the window, when elevated at an angle, and also to the ground when its end was
FIRE-ESCAPES.

Mr. Robert's machine.

The lever has an arch or toothed sector attached to it, beneath the centre, and this was worked by a pinion with wheel-work, by which two men, turning a handle and standing upon the platform, could command the elevation of the lever, and the basket attached to it. By raising the end to the height of the window, and turning the vertical axis round, they could make the end of the lever enter the window, and the persons having put themselves into the basket, the end was to be a little raised, then by turning the vertical axis the basket was brought over the street, and lowered safely down by the men at the handle. The basket could again be elevated, and another person brought down with equal ease. The only objection to this machine is, that the lever would require to be of such a great length, and having no support at its ends, would require a cumbersome framing, to render it sufficiently strong. A simple and effective mode of trussing would be Mr. Smart's plan of dividing the road lengthwise by a saw kerf, and introducing blocks to swell the beam in the middle, and give it stiffness, as we have before described of the ladder. A boom and stays, to act like the shrouds of a ship, would give it great strength without any increase of weight.

The Society of Arts have published, in their thirty-first volume of Transactions, descriptions of two fire escapes or elevators. They consist of a number of bars jointed together in pairs, by a pin in the middle of each like a pair of shears. To the upper ends of each of these the lower ends of a second pair are jointed, and to these a third pair, and so on of five pairs. The whole assemblage will therefore consist of similar parallelograms placed one upon the other. Now, by forcing the lowest ends of the levers to approach towards each other, the parallelograms are caused to elongate in the vertical direction, and raise up a platform to the required height. The machine, when elevated, forms a lofty tower, within which a regular range of ladders are placed in the manner of a staircase. The contrivance is ingenious, but by many as applicable to the purpose, from its complexity. One of these machines is composed of 24 levers, and 8 ladders, besides the smaller parts. The other machine has 40 levers and 8 ladders within it.

Of the other kind of fire-escapes, which are to be fixed from the window, the most simple is a rope-ladder, with wooden rails for the steps; but, unless a post with a hook is fixed below in the street, to attach the lower end of the ladder to it, and strain the ropes tight, it is extremely difficult to descend.

Another species is called the sling fire-escape. This consists of a rope, to which the person fastens himself by a girdle, and throwing himself out of a window, is lowered slowly down, the rope having some contrivance to cause a friction or resistance, which will prevent any acceleration in the motion. The simplest of these has a long rope provided with two straps or belts, one to buckle round the waist of the person who is to descend, and the other to pass under him, so that he sits as in a swing when suspended by the rope, which is rather more than twice as long as a height of the window from the ground. The rope is made to pass through a double eye or iron ring, suspended from a hook fixed over the window; then the other end of the rope is brought down to a piece of wood called the regulator, which is attached to the girdle strap, that the person wears. This piece of wood has three holes in it, and two deep notches, into which the rope is woven, and will thereby have so much friction in passing, as to make it slip through regularly, and quite at the command of the descending person who is to hold the rope in his hand; and by letting it slip more or less, he can easily regulate his descent. This plan was proposed by Mr. Forster.

Another machine, invented by Mr. Masereis, had the same arrangement, except that the rope, instead of passing through the iron ring or eye above mentioned, is wrapped three or four times round a small cylinder, made with a proper spiral groove, and fixed in an iron shank like the strap of a pulley, but rivetted fast, so that it cannot turn round. By means of a hook in this shank, the cylinder can be suspended from the hook which is fixed over the window. The groove in this cylinder causes so much friction in the passage of the rope, that the person who is suspended has an equal command as in the other method; but, without passing the rope through the notches in the piece of wood, he can command it when he holds the other end of the rope in his hand, and lets it slip more or less at pleasure.

Another machine, which was exhibited in London, was contained beneath a stool, to stand by the bed-side. On an alarm, this stool could be instantly fixed to the window, by hooking two of its legs over the sill of the window, in the same manner as the boards used by a painter to support himself whilst he paints outside of a window. Beneath the stool was an axle, upon which the rope was wrapped two or three times; a small wheel was fixed on the end of the axle, and a gripe inclosed this, with a spring to cause sufficient friction to retard the excessive motion of the wheel and axle. The spring was regulated by a screw, to bear upon the wheel with any required force, in proportion to the weight of the person who was to descend. A strap was placed at each end of the rope, so that when one had descended, the girdle-strap at the opposite end of the rope would be ready for another person to come down.

Mr. Salmon has contrived another machine, which appears superior to any of these: It is a large pulley, placed in an iron strap, by which it can be hung up over the window. It is made with a deep angular groove, so that the rope which passes over it cannot slip; and, to render this more secure, the groove has several sharp pins fixed in it; the rope has a girdle-strap at one end, and a sufficient counterweight at the other, to make the rope apply so firmly to the pulley that it cannot slip, and also to draw up the strap the moment the person who has descended has ungirdled it. The pulley has a toothed wheel fixed against it, which acts in the pallets of an anchor-escapement, fixed on an axis, placed in the same iron frame or sling, above the axis of the pulley. A short pendulum, with a heavy bob, is fixed on the end of the arm of the anchor or pallets. By this contrivance the pulley is regulated, as the escapement will not suffer it to move with any more than the intended velocity; and if the pallets of the anchor are formed of a proper shape, as will be described in the article Horoloov, it will make very little difference if the weight which descends is a small or a great one. The escapement-wheel is attached to the pulley by a ratchet-wheel and click, which admits the counterweight to draw up the strap-girdle, without acting on the escapement, as soon as the person who has descended quits it; and the machine is then ready to let down another person.

Another fire-escape, to affix to a window, is composed of a strong sail-cloth, sewed up, to form a long bag or sack, which is open at one end, and of such a

An escape for infirm persons.
length that it will reach from the window to the ground when inclined in an angle of 45 degrees. The upper end of the sack is extended by a hoop sewed into it, and has a cluster of small cords, very similar to the suspension of a hammock, which proceed from different parts of the hoop, and all join in two rings, by means of which it can easily be suspended from two hooks, at the sides of the window-frame. The lower end of the sack is sewed up, but it has an opening in the side, sufficient to let out a man; and the borders of this opening must be well hemmed with a cord to make it strong. Two cords are also made fast to the end of the sack, by means of which the lower part can be lashed to any post or other fixture at the opposite side of the street, to stretch and retain the sack in the inclined position. The use of this contrivance is evident, as it forms a practicable inclined plane, in which any person can safely slide down to the bottom, and be taken out at the side-opening. It has the advantage of all the others, because women, children, or infirm persons, however distracted by fear, can be put out of the window into the hoop, and will arrive safely at the bottom; whereas the other contrivances with ropes, though equally safe in reality, have so much more appearance of danger, that there would be some difficulty in such cases. It is scarcely necessary to add, that the sack must be made very narrow, so that a person can only pass easily through it, and they will then be able to regulate their descent, by extending their arms and legs, although the width of the street should require the inclination to be greater than 45 degrees. In case there is no sufficient fixture to lash the lower end of the sack to, it must be held by two or three people, who, indeed, if they are careful, will do it more effectually than a fixture, by raising the end when a person comes down towards the lower end, so as to check the descent. For this purpose, two or three rope handles are provided on each side, at the lower end, for the bystanders to hold; and these are equally useful when the end is lashed fast. It is plain, that goods of small bulk can be sent down by the same means; but, to prevent any accident of stopping up the sack, the hoop at top is made smaller than any other part.

A new fire-ladder, and an elevator for supporting and raising the leather pipe of a fire-engine, have been invented and constructed by Mr William Lamb, builder in Leith. The fire-ladder is nearly upon the same principle as that of Mr Davis, which we have already described. It consists of three ladders, one within another, the two innermost being elevated upon the outermost by a rope and pulley, and if necessary by the aid of a windlass. The elevator consists of two square tubes and a square beam, the first square tube containing the second, and the second containing the square beam. All these are supported in a vertical position by four legs, the lower extremity of the first or outer square tube resting on the ground. By means of a pulley moved by a windlass, the second square tube can be elevated upon the first, and the square beam upon the second square tube, to the height required. About four or five feet below the top of the square beam is fixed a platform, upon which the fireman stands while is raised to the necessary height for the purpose of directing the pipe of the engine, the end of which is fixed upon an universal joint on the top of the beam, so that the fireman has no weight to support, but is solely employed in directing the pipe to the proper part of the building. We are glad to learn that the magistrates of Leith have ordered both these ingenious machines to be constructed for the use of the town, and we trust every other town in Scotland will follow their example. The expense of the ladder when about 42 feet long will not exceed £5; that of the elevator £15 or £14. The elevator may be applied to many other purposes; and Mr Lamb proposes also to construct it, so that any person may raise himself.

An account of a fire-ladder which supports itself, will be found in the Acta Petropolitana, vol. i. p. 1. See also Leopold's Theatrum Machinarum, tab. 54, 57; Emerson's Mechanics, 228; Varcourt, Mem. Acad. Par. 1761, Hist. 158; Collins, American Transactions, tom. iv. or Repertory of Arts, vol. x. p. 25; Audibert, Mem. de Institut. tom. iv. or Repertory, vol. i. p. 439. (s. v.)

**FIREWORKS. See Pyrotechny.**

**FIRST, in Music, sometimes implies the first, and sometimes the second chromatic degree of the scale: thus, First Major (I) has the ratio: 153:475 = 4752-14f-1m, called also the sharp minor first, and is the SEMITONE MEDIAN (S), which see.**

**First Minor (1), has the ratio 1, and the length of string 1, but is without magnitude, and consequently its logarithms and notations of all the different kinds are 0: it is called the Unison, Equissonant Prime, Homophony, Istesso; and by Mr Overend, in his manuscripts, it is called Radix, and marked with an R, having a dash across its last stroke. ---

**FISHERIES.**

It has been admitted by our own, as well as by foreign writers, that Britain, and her dependent islands, are most advantageously situated for the various and valuable fisheries, with which their lakes, rivers, and seas abound.

At an early period of our history, the fisheries not only became an object of serious attention to individuals, but attracted the particular notice of government, on account of the important objects to which they might be made subservient.

Among the many kinds of food which are given for the subsistence of man, fish is one of the most wholesome and abundant; and such is its powerful influence on population, that it is generally allowed that the empire of China owes the immense number of its inhabitants to the astonishing quantities of fish with which they are supplied. Britain, however, we apprehend, may boast of a greater and choicer variety than even China; for, out of about four hundred species, as described by Linnaeus, we can enumerate nearly one hundred and fifty to be inhabitants of our own waters, and almost all these are esculent.

Those chiefly distinguished in our established fisheries are cod and herring, with their numerous congers, mackerel and salmon. These, when pickled or dried, find at all times a ready vent in the European continent, or West India islands. For the other kinds which we have not here specified, there is always a demand, either as fresh, green, or cured fish, for home consumption.
FISHERIES.

The figure and vast extent of our indented coasts, afford many advantages for procuring that fine variety of fish with which our seas are stored; and, from whatever point the wind blows, we always have some tracts out of the reach of the weather, where our fisheries can be carried on, whether for inland use or exportation. We also have, in every direction, ports, harbours, and bays, to which vessels during heavy gales can easily and speedily run; and our shores furnish us with all kinds of natural fish for food, that are taken with the fish-net and hook, as lamprey-guts, razor shell fish, cockles, limpets, whelks, &c. We have a full command of materials for ship-building, and for making fishing tackle of every description. By proper care and management, our salt might equal, if not exceed, the best salt formerly used and prepared by the Dutch in the curing of their fish, and to which their superiority in point of flavour was we believe generally, and we think justly, ascribed. The inhabitants of the British isles not only possess greater capitals, but are noted too for intelligence, and for a spirit of enterprise far above those of other nations.

Notwithstanding these advantages, our fisheries have not only never been prosecuted to their utmost extent; but, in spite of the many bounties and privileges attached to them from time to time, they have been on the decline for several years past. *

We cannot easily ascertain the causes that have led to this failure; but it is a matter of severe disappointment that this branch of our commerce has not been managed so prosperously as our flattering situation gave us reason to expect. In order to remedy this evil, that public spirited body, the Highland Society of Scotland, after great exertion and careful investigation, discovered and pointed out many of the errors and abuses which had long prevailed in that valuable branch, the white herring fishery; and by means of their reports, a bill was brought into Parliament, and enacted. This act is dated the 25th of June 1808, and the provisions of it took place from the 1st of June 1809, and were to continue in force until the 1st of June 1813, and from then to the end of the then next session of Parliament, (1814). Some amendments were at that time proposed, and with these we suppose the same act either has or will be renewed. It is a spirited and fair experiment, and we hope will afford a proof of the utility and many advantages that must accrue to the state from a persevering prosecution of all the branches of the deep sea fishing. Yet, at the same time, we must remark, that this act is not without its imperfections; and it is to be regretted that it did not embrace regulations for some of our other fisheries, which so palpably require parliamentary interference, such as conservancies for our salmon rivers. Had the commissioners in that act been appointed as a court of conservancy, with a power, according to local situation, to constitute district courts under them, it might have saved that fishery from an unimportance to which it is fast verging. The use of stake nets, † and the wanton and prodigious destruction of the fry in various parts of the country, have been very injurious to this fishery. It would have been well, too, had it held out great and particular encouragement for a junction of the cod with the deep sea herring fishery. This might have lengthened the time of fishing to the greatest part of the year, which would have kept the busses, ill adapted for any other trade, almost in constant employment; and, of course, induced the owners to procure more small vessels, to fish, as well as to the masters, upon the expiration of their indentures, liberal premiums might have been granted. The accomplishment of such a plan would have formed a nursery of the most hardy and intrepid seamen. The last observation that we shall here make on this act, is, that the bounty which it offers is too small, particularly if it is considered, that it was augmented from thirty to fifty shillings so far back as the year 1757. Had it been five pounds in place of three pounds per ton, the increase would have kept pace with the depreciation of money and the advanced prices of materials.

It may be necessary, also, in this place, to mention the objections made by adventurers in that fishery, to the hardships (as they alleged) attending the former bounties, leaving it to our readers to determine if "The Act for the further Encouragement and better Regulation of the British White Herring Fishery, 1808," applies remedies to all these complaints; and whether they were then, or are yet, well or ill-founded. They are as follow: "That the fishing vessel must go to a certain port; the equipage must pass in review before the officers of the customs; the ship must complete her cargo, or remain three months at sea to do it;—so that, if in the first week she procured nine-tenths of it, she would be obliged to keep the sea for the other tenth. The ship can take no instruments but those proper for the fishery to which the premium is applied; the cargo cannot be discharged but in a certain port;—there are general formalities to be observed with respect to the salt which she carries out and brings home;—the owners are exposed to vexations from custom-house officers, and to law-suits which they are obliged to carry on in courts of justice far from their residence." Such have been in part the causes assigned for the decline of this fishery. Many, too, are the prejudices formed against granting bounties to the busses employed in the deep sea herring fishery. It has been, and is still contended, that the support given to them is too lavish, and that they ought to be left to stand or fall according to their own weight.

We have seen various schemes, and various proposals, for untried and more vigorous efforts in the prosecution of our fisheries; we applaud every suggestion that can be offered for that purpose, although we cannot approve of any we have yet perused. A national fishery, on a grand scale, has been recommended; and the following are the outlines, as given by an anonymous author. ‡

"1. A grand national corporation organized under the immediate protection and superintendence of parliament. 2. A capital stock of ———— to be raised in shares by the sea-port towns and corporations, proportioned to the advantages of locality, and amount of their trade and tonnage; an annual dividend of five per cent. guaranteed on the capital. 3. Conveniences

* We must, however, in these general observations, except the whale fishery, which has of late been carried on most successfully, and almost exclusively, by this country.

† This destructive practice is in some degree now removed; for the Court of Session gave a decision in 1815, declaring stake nets, whether fixed or floating, illegal, and prohibited all the proprietors on the river Tay from using them. An appeal to the House of Lords, in consequence of this judgment, was however lodged, and lies there yet undecided.

‡ Plan of National Improvements, &c. 1819.
3,686,760 in one of a middling size, which weighed 12,540 grains. The flesh is white, firm, comes off in flakes, exceedingly good, and held in highest estimation in every part of the world, except by the inhabitants of Edinburgh, than that of its congener the haddock, (Gadus agleratus). Various are the names given to it, both when fresh or pickled,—cod, hailfish, cabillow or cabillib, green fish, Iceland or mud-fish, Aberdeen fish, North Sea cod, stockfish, barrelled cod, poor John, and, throughout Scotland, when dried, hard fish. Their young, and those under 20 inches, are called codlings. They generally spawn with us from February until the middle of April, and sooner recover than any other fish from their spent state; for, in a few weeks, after having shed their roes and milts, they appear plump, well coloured, and full about the tail. This species is infested with a variety of vermes, as the Gordius marinus of Linneus, the Echinokrhychnus, the Cuculatus marinus, the Fasciola piscium, the Tenia vesca, all of which are to be found at times in their intestines, and the Lernoa asellina in their gills and pectoral fins. There is no fish of more general use, and more suitable to all palates, than the cod; and it is in plenty, and fit for eating, in some or other of the waters which encompass our islands, at almost every time of the year. It is to be found on both sides of the northern hemisphere. A cold climate seems to be rather its choice, as the region which it prefers in Europe is from 50 to 65 latitude; that is, from near the Scilly islands to Iceland; and in America, from about 41 to 58 latitude; that is, from about Rhode island to the shores of the Eskimians.

The cod fishery, in which we include, of the same genus, the ling (Gadus molus), and tusk or tork (Gadus bremse), forms the most extensive fishery of which Britain can boast; for we have not only the range of our own islands in Europe, but the vast banks of Newfoundland and the fishing grounds along the shores of Nova Scotia, St. John's, Cape Breton, and in the Gulf of St. Lawrence: all of them seas noted for the quantity of this valuable fish which they afford.

It was found expedient, by the late act of parliament, to give what was thought a liberal encouragement to decked vessels of considerable burden, in the prosecution of the deep sea herring fishery; but it certainly must be allowed to be fully as necessary and suitable to that of the cod. Herrings lie commonly nearer the shore; and as they are not so often found in the strong rapid currents as the cod, the use of small open boats is improper and injudicious for that fishery, unless it be with the view only of affording a temporary supply of fresh fish for the inhabitants of the coast.

The fisheries, indeed, are carried on by the natives of Scotland (with a few exceptions) in a very awkward and slovenly manner. The common method of taking cod, ling, haddock, &c. is to go out only a few miles from the shores of their fishing-towns, with a crew consisting of four or five hands, sometimes one or two of them boys; in an unprovided, undecked boat, carrying with them many tires of long lines, which they oftener set than fish with. These they drop on the grounds where they think the fish lie; and, when the weather is in the smallest degree boisterous, they leave them attached to near's bladders all night, and indeed frequently for many successive days and nights; that is, until it becomes so moderate as to suit their choice and convenience to return. They then draw up their
lines, find the baited hooks stuck in the stomachs of the fish, or the fish exhausted by long struggling, or dead, or eaten into the entrails by vermin. In this condition are what they call fresh cod, fresh turbot, and other kinds of fish caught by the line and hook, offered to sale in our markets. Let us now observe the modes that the English and Dutch practise in the management of their lines, both for what fish they are to sell fresh, and also for such as they mean to cure. In spring and summer they use short, and in winter long lines, on account of the cod keeping nearer the bottom in that season, and which (according to the fisherman’s phraseology) they always keep bobbing, that is playing backwards and forwards by little and tremulous jerks of the hand and arm, by which means, as in angling, the line and hook are in continual motion; and, feeling the fish the moment he bites, they instantly haul him up. They are therefore all caught by the lip or mouth, which saves a great deal of time, as the fisherman is immediately enabled to renew the bait, not having to extricate the hook either from the gorge or stomach; besides, they are all taken alive, without being torn or mangled, a consideration of no small importance.

In this manner, on the cold and uncomfortable banks of Newfoundland, each expert fisherman, although he can take but one at a time, will catch from two to three hundred of their heavy fish in a day. This is the most valuable cod-fishery in the world, and may be now said to belong entirely to Great Britain. The island is situated between Lat. 40° 45' and 51° 40' North, and between Long. 26° 31' and 59° 40' West. The grand bank is about 70 miles from it, and is 400 miles in length, and 200 in breadth, not including the Jaquet and Green Banks, &c.: the greatest and best part of it lies to the south and east of the island. The depth of water, according to Governor Pownall’s chart, varies from 24 to 60 fathoms. The immense shoals of cod, with the variety of other fish which inhabit the grand and lesser banks, excite astonishment.

In these regions an unceasing warfare is carried on; fish against fish, the larger devouring the smaller, not even sparing their own species. The cod is seemingly the most powerful, being generally the largest and most voracious. The greatest number, as well as the fattest and bulkiest fish, are to be found where the water is, with a sandy ground; on the contrary, they are lean and scarce where the water is still, upon an oozy bottom; and the depth to which they seem mostly attached, is from 30 to 40 fathoms—particulars which fishermen and seamen soon learn, by their being most successful in these soundings.

This fishery gives freight to nearly 300 vessels, from one to two hundred tons burden each. They are mostly fitted out from Guernsey, Jersey, Ireland, and ports in the English Channel, as Poole, Dartmouth, &c.; they carry about 35,000 fish each, upon an average; their chief markets are Spain, Portugal, Italy, and the Levant; for the other parts of Europe are commonly provided with those taken in the British seas, the Dogger, Wale, or Wessex banks, and other parts of the North Sea. Besides these large vessels, there are at least 2000 small-decked craft, or shallop, from 12 to 20 tons burden, rigged like the luggers in England employed in the fisheries along the shores of Newfoundland, Nova Scotia, and the islands of Cape-Breton, a great part of whose hands is taken up on land, in erecting stages, and in curing and drying their fish. The principal scene for this employment is on the coast of Placentia Bay, which opens between Chapeau-rouge Point westward, and Cape St Mary on the east. When a vessel has taken her station on this or any other bay, she is immediately rigged, leaving only the shrouds to sustain the masts.

The livers of the whole genus Gadus, yield a well-flavoured oil. The sounds and tongues of the cod are also salted and barrelled, and are much esteemed as dainties, in the islands and continent of America. Mr Morse, the American geographer, says, (we, however, suspect the account is somewhat exaggerated,) “Great Britain, and the United States, at the lowest computation, annually employ 5000 sail of small craft in this fishery; on board of which, and on shore to cure and pack the fish, are upwards of 100,000 hands.” In our article England, Vol. IX. p. 14. we have already given an account of the quantity of fish caught, and of the number of vessels, &c. employed in the Newfoundland fishery in different years.

Of late years, the English have sent a number of wellled smacks, stoutly manned, to the island of Orkney, where they fish in the deep water, and strong currents, along the banks of the Pentland Frith, Cape Wrath, and the adjacent headlands. In the prosecution of this fishery, they have been extremely successful; and although at such a distance, have afforded a great and excellent supply of fresh cod, and also of new cured fish, for the market of the metropolis.

The owners of these wellled smacks are Saunders, Selby, Cresswell, and a few other fishermen of Billingsgate, who employ about 40 of these vessels. They rendezvous in Long Hope, Orkney, from whence three or four run weekly for the Thames. When they arrive at Queenborough, they unload, and then send their fish in small boats up to London.

Sect. II. On the Herring Fishery.

The name herring is derived from the German word heer, signifying an army, as expressive of the numbers in the great shoal, which annually appear upon the northern coasts.

Our common herring is from 7 to 12 inches long; a fine silver colour shines upon the belly and sides, the back somewhat greenish; the scales are large for the size of the fish, and come easily and regularly off; the lines are small, and not easily perceived; the under jaw is a little longer than the upper; the dorsal fin consists of seventeen, the ventral fins of nine, the pectoral seventeen, the anal fourteen, and the tail forked with eighteen rays. He dies instantly when taken out of the water.

This is the Clupea harengus of Linnaeus, Romdeulius, Gesner, Willoughby, and Ray. The Hale of the Romans, we suspect, was not a herring, but rather a preparation from some other fish, as the Botargo, the precious Garum, or something resembling our modern essences, for fish sauce.

The Shad, or as called by some authors, the mother of herrings, (Clupea alosa,) is the only one of the genus that betakes itself to fresh waters, and in Britain is only to be found in the Thames and Severn, where it is supposed to ascend, for the sole purpose of spawning.

In the months of November, December, January and February, herrings generally deposit their ova on the Fuces palmatus, dilisk, (called in Scotland dulse,) or Utea, laver, and other sea-plants, and sometimes on gravel. They are there impregnated by the milt, and become animated in April, or beginning of May. The herring is a prolific fish; Mr Harmer, after examining
one of a middle size, found the weight of the spawn to be 480 grains, and, the number of eggs 36,960.

As the heaviest salmon are found in our large rivers, so are the largest herring in our deep waters; and if we minutely observe, we shall find each coast and river to produce a fish, although bearing the same generic and specific characters, different in taste, size, and appearance. It is well known in the salmon, and no stronger instance of this fact can be given, than that of the shad of the Severn and the Thames; the flesh of the first is fat, rich, and delicious, brings a price equal to salmon in the market; and appears in April and May; that of the latter is lean, and insipid, and does not enter the Thames till July. A distinction equally striking is to be noticed in our west and east country herring, although all detachments from the same great original army or shoal.

The varieties of our herring may be reduced to two or three sizes. In the bays and lochs of our Western Highlands, they are not only larger, but superior in taste and flavour to all others: from 650 to 800 fill a barrel. Those of the Friths of Forth and Tay require about 1000 to 1100. High up the Murray Frith, it takes about 1500 to the barrel.

It has been a matter of curious inquiry, how far to the northward these herrings proceed, after leaving our shores. We imagine that Mr Pennant and some other naturalists have mistaken the winter residence of the herrings, who say, "they return to their parental haunts beneath the ice, to repair the vast destruction of their race, during summer, by man, fowl, and fish." For what purpose they should have received an instinct to return to the Polar seas, is to us incomprehensible. Surely the icy regions are unfavourable both to life and vegetation, and consequently for animal food. The salmon, the shad, the smelt, are never found at sea, yet it is never said that they depart to any great distance from our shores. The most reasonable conjecture we can form, is, that the herring, like our other migratory fishes, take to the deepest parts of the ocean. None of our voyagers nor whalers ever pretended to have seen them to the northward (if even so far) of the 67th degree of latitude.

The Dutch, who formerly fished but a little way from Shetland, would have undoubtedly begun their fishing sooner than the first of July, by meeting on their passage the herring shoals farther to the north, if such an immense body issued from within the arctic circle. So far, indeed, from their betaking themselves to such cold quarters, they often remain here during the winter; and to-day (19th March,) we have examined some, which were taken in the Forth in the morning, containing both milts and roes. We acknowledge, that their case is here so long, and being so late in spawning, are circumstances very unusual.

In migrating from the deep seas to our shores, the herring seems to be prompted by a similar instinct to that of the shad and salmon, of casting its spawn in its native waters; however, they are more desultory in their movements than either of these fishes.

From the Friths of Forth and Tay, about the year 1788, both haddocks and herrings took their departure, and did not return for nine or ten years. Various reasons have been assigned for such seemingly capricious movements. The alteration in banks and currents is said to make them change their situation. The Norwegians affirm, that the burning of seaweed in the manufacture of kelp, has forced the herrings to leave some of their shores. It is, indeed, probable, that the glare of kelp fires affects them with the same kind of terror which they have for lightning, and for that luminous appearance in the sea, called by fishermen, waterburn.

About the end of June, or rather early in July, the great shoal of herrings, seemingly from the north, appears towards the extremity of the Shetland islands. Gulls and gannets, screaming and in flight; whales and porpoises, rising and tumbling in the water, are the never failing harbingers of the approach of this immense body of fish, forming a surface or extent of several hundred miles. A great rippling in the sea is also observed; and sailors and fishermen aver, that they can nose them from afar by their strong oily smell. Soon after they come near to Shetland, they separate into various large divisions, some takiing to the western and others to the eastern shores of Great Britain and Ireland. A few of these columns likewise cross the North Sea, or German Ocean; and the Swedes, about 1730, discovered a valuable herring fishery near to Gottenburgh, and which, from its contiguity to the Baltic, enabled them to undersell both the Scotch and Dutch, who formerly engrossed the whole of that trade. From their first arrival in July, they keep along both the east and west coasts of Scotland, and in October, after many erratic movements, they fix their residence where they mean to spawn. In these places they continue until the end of February, (sometimes, but rarely, longer,) and constitute what we call our winter fishery. In the Frith of Forth, for these several years past, this has been a very productive fishery; and during the present winter, 1814-15, the numbers of herrings there taken, and brought to the Edinburgh markets, have yielded a most abundant supply of nutritious food for the poorer class of inhabitants of the city and its neighbours.

After the states of Holland became independent, (1789,) the herring fishery was carried on to an amazing extent; indeed the accounts given of it by various writers appear at this day almost incredible, although they, upon the whole, seem to be well authenticated. Sir Walter Raleigh was of opinion, that the Dutch made ten millions per annum of this fishery in his time. The great statesman De Wit, assures us, that in the year 1667, the Dutch employed no less than 2000 busses, and that upwards of 800,000 persons were subsisted in the two provinces of Holland and West Friesland alone by the herring fishery. The rise of the united provinces to their great importance as a nation, and to their being at one time rivals to the English in their marine, was entirely attributed to their perseverance and success in the herring fishery. The splendour and commercial consequence of their towns, sprang also from the same source, and it is acknowledged by themselves "that Amsterdam had its foundation on herring bones."

The great wealth, which the herring fishery, at an early period, brought to the Dutch, induced the Scotch to embark seriously into the same concern, and accordingly it was enacted, "That certain lords spiritual and temporal, and burrows, make ships, buses, and boats, with nets and other pertinents," Jam. III. Par. 6, cap. 49. This act was confirmed by James IV. "that ships and buses, with all their pertinents for fishing, be made in each burgh, in number according to the substance of the burgh, and the least of them to be of twenty tunn." Par. 4. cap. 49.

Letters patent were granted by Charles I. to establish the Company of the Royal Fishery of England. This erection was, however, rescinded by an act of William and Mary; declaring it to be dissolved.

The first bounty for the exportation of herrings, was
FISHERIES.

granted by the Scotch Parliament in 1705. A bounty of £18 per tun. Scotch was then paid on every last of herrings exported in whatever way they were caught, and upon the last taken by busses and exported £18 Scotch was allowed. The same act remitted the duties payable on all materials used in the fishery.

Two years after this enactment, the Union took place, from which period the herring fishery seems to have been in a declining state, in spite of all the props, with which it has been supported, and the liberal premiums given for its revival. In 1720, a general company was formed for the purpose of raising this fishery from its languor. It consisted of about 2000 of the principal people in Scotland; their capital was divided into shares of £100 each; but, like the South Sea bubble, which burst about the same time, the whole concern soon vanished into air.

In 1727, the Board of Trustees was established, to whom the management of £2000 per annum was given from the revenue of Scotland, for the encouragement of the manufactures and fisheries of that country. We cannot say what part of this sum was, or is now appropriated for the herring fishery.

In 1750, the Free British White Herring Company act passed in Parliament, whereby it was enacted, that a capital might be subscribed of £500,000, the proprietors to receive 3 per cent. per annum, upon the sums paid in during fourteen years. A bounty was also allowed of 30s. per ton for all busses from 20 to 80 tons employed in the service of the company. His Royal Highness the Prince of Wales, (who was enthusiastically fond of the undertaking;) was chosen governor. This national association, although patronized by the first people in the kingdom, and promising fair in every point, was soon after its establishment given up.

By this act it was likewise declared, that every fishing company, at any port in Britain having a capital of £10,000, should also be entitled to the same premium and bounty as allowed to the aforesaid Free British White Herring Company. Neither did this appendage to the act succeed better.

In 1753, 1755, and 1756, three other acts of parliament were passed, regulating more particularly the mode of fishing with busses. Another act took place in 1757, by which the bounties to busses were increased from 30s. to 50s. per ton. This liberal encouragement induced many owners of vessels to enter as adventurers in this trade; and in the course of the year 1767, so large a sum as £31,906 was paid in Scotland to persons engaged in this fishery. By an act passed in 1771, this bounty was again restricted to 30s. per ton, by which means the bounties paid in Scotland became trifling, and in England, for one or two years, no bounties for herring busses were claimed.

In 1779, another act was passed, followed by an interim one, by which the herring fishery continued to be regulated, until the Highland Society of Scotland took up the business of this neglected, ill-conducted fishery, by investigating the causes of its decline, and the means most likely to bring about its revival and improvement. The steps which they thought necessary to take for these purposes were, to offer liberal premiums for approved essays on the Natural History of Herrings, containing observations on the causes that induce them to leave their usual haunts, the modes of capture that have a tendency to render the fishing less productive, &c.

Having received several communications on the above subject, and after much investigation, and various correspondences relative to this fishery, the Society, with the assistance of other gentlemen, set about framing a bill, that was brought into parliament in 1805, when it passed; of which the following is an abstract.

It is entitled, An act for the further encouragement and better regulation of the British White Herring Fishery, until the first day of July, and from thence to the end of the then next session of parliament.

A bounty of £2 per ton shall be paid annually to the owner or owners of any whole decked buss or vessel of not less than 60 tons burthen, being British built, owned, navigated, and registered according to law, which shall be fitted out for, and actually employed in the Deep Sea British White Herring Fishery, but that such bounty shall not be paid on any number of tons more than 100, although the buss should be of greater burden.

For every barrel containing 32 gallons of white herrings caught in the British fisheries, and landed in Great Britain, a bounty of 2s.

The number of trustees for manufactures, fisheries, &c. in Scotland, to be increased from 21 to 28, whereof his Majesty may appoint seven to be commissioners for the herring fishery.

The Admiralty to have the appointment of an officer of the navy to be superintendent of the Deep Sea British White Herring Fishery, who shall annually proceed to Brassev Sound in Shetland, and be at this place of rendezvous by the 15th of June, and shall remain with the vessels employed in this fishery during the continuance of the season, and shall from time to time, when required, transmit to the commissioners of the Admiralty, as also to the commissioners of the fishery, a list of the busses employed in the said fishery, with the number and ages of the men on board thereof, distinguishing the capacities in which they respectively act.

The Treasury to appoint officers of the fishery, to inspect and take account of all herrings landed or exported, and to certify whether the fish are properly cured and packed, so as to be entitled to the bounty of 2s. per barrel; and in order that such officer may be duly qualified for this purpose, they must have exercised the trade of a cooper, and be otherwise skilful in this business.

No net to be used that has a mesh less than one inch from knot to knot.

No buss or vessels to be entitled to the tonnage bounty thereof, unless such vessel have on board (put up in new barrels) sixteen bushels of salt at the least, for every hent of herrings which such vessel shall be capable of containing, and also as many more new barrels as such buss or vessel is capable of carrying; nor unless such buss shall have on board 300 square yards of netting at the least, for every ton of her admeasurement, together with the customary quantity of other materials, for the equipment and mounting of the quantity of netting hereby required to be provided; nor unless she be manned with the number of men following, at the least; that is to say, with ten men, if such vessel shall not exceed the burthen of 60 tons; if she shall exceed the burthen of 60 tons, and shall be under the burthen of 70 tons, with 11 men, and if such buss or vessel shall be of the burthen of 70 tons or upwards, then with one man more for every ten tons by which such vessel shall exceed 70 tons, two of which number respectively may be foreign seamen, experienced in the deep sea herring fishery. A vessel of upwards of 100 tons is not required to have more men, salt, or net-
Fisheries.

Herring

fishery.

The full number of men, as above stated, are not deemed necessary until the arrival of the buss at the rendezvous of BrasseY Sound.

The owner or owners, in order to obtain the tonnage bounty, is to give notice in writing to the officer at the port of sailing, the name of the buss, of the owners of the master, the quantity of salt, netting, number of barrels, &c. and declare that such vessel is sufficient, and in every respect fit and proper for such voyage and fishing; and if the officer is satisfied that every proper regulation has been complied with, he shall certify the same on the back of the notice, and one or more of the owners or their agent, and the master of such vessel, shall respectively make oath before an officer of the fishery, that it is truly his determined purpose, that such vessel as then furnished and provided, shall forthwith, after license shall be granted, proceed to BrasseY Sound in Shetland, and be there on or before the 22d day of June (having on board the number of men required), and shall not wet or shoot her nets before the 24th of the same month, and shall fish for herrings in the Deep Sea Fishery, in the manner following; that is to say, the crew shall shoot and haul the nets directly from and into the said buss or vessel, without the intervention or use of a small boat, the nets being attached to the vessel while they are set, the vessel not being at anchor when the crew are shooting the nets, during the time the nets are set, or while the crew are hauling or taking them in; and shall cure all the herrings taken or caught in the said nets in barrels, and not in bulk on board such vessel, and that the crew shall continue fishing upon the coasts of Great Britain and Ireland, from the said 24th of June until the 15th of September, the owner giving bond, with sufficient surety, (which is exempted from stamp duty), that all requisites have been performed, then the officer of the fishery shall give to the master a license to proceed on his voyage to the rendezvous.

After the vessel has arrived at BrasseY Sound, the superintendent, if satisfied that she is completely stored, and has on board the number of men required by this act, then he is to give a certificate declaring that the said buss is entitled to commence the said Deep Sea White Herring Fishery for the tonnage bounty. Herrings taken every day by the crews of the busses to be distinguished by a mark on the barrels in which they are cured.

Herrings may be transhipped out of a buss at the Deep Sea Fishery into another vessel, previously to the 15th of July, and carried into port.

The master of every buss employed in the Deep Sea Fishery, must keep a regular journal, in order to be entitled to claim tonnage bounty.

Commissioners of the fishery to enquire into any matter of complaint stated in the report of the superintendent, against the conduct of the master or crew of any buss, and determine thereon.

The officer of the fishery at each port to attend the landing of the herrings, and of the salt and barrels which have not been used out of each buss, and take account thereof, and certify the same.

The officer of the fishery at each port, shall transmit, without delay, the license, the master's oath, and the officer's certificate made on the return and discharge of each buss, &c. to the commissioners; and if they shall be satisfied that all regulations directed by this act have been observed, they shall immediately give a debenture to the owner, with a notice of their having granted such to the commissioners of Excise in England or Scotland, who are to give an order to their cashier or collector nearest the port where the buss discharged her cargo, who is to pay the sum mentioned in the debenture on demand.

Mariners employed in the deep sea fishery are protected from being impressed during the voyage, and until after the buss has returned to the port of her discharge.

Owners of busses entitled to the tonnage bounty, to pay the crew 2s. per barrel on the herrings taken and cured by them.

An additional bounty of £1 per ton is allowed for the first 30 busses fitted out for and employed in the herring fishery, and entitled to the bounty of £3 per ton.

Then follow regulations for cleaning out vessels, (other than busses on the tonnage bounty), with salt, &c. for the British herring fishery, what herrings shall be entitled to the bounty of 2s. and certain herrings are prohibited from being exported.

Herrings may be cured and packed in half barrels, containing 10 gallons English wine measure, and two of these being accounted equal to one, 2s. bounty shall be paid on them.

For encouraging the inhabitants on the sea-coasts of Scotland, to provide larger boats than are now used in the herring fishery, and to take herrings at a greater distance from shore than can be done in small boats, it is enacted, that after the 1st of June 1809, the commissioners are authorised to allow premiums or bounties, not exceeding the sum of three thousand pounds yearly, to persons who shall employ boats of a burthen not less than fifteen tons by admeasurement, in the taking herrings on the coast of Scotland, and who shall cure and pack them according to the rules and regulations of the commissioners. This bounty also to be paid by the commissioners of Excise in Scotland.

When the foregoing act expired, which was at the close of the last session of parliament, (1814) an interim one took place. This was a temporary expedient, until a bill should be brought in this season, after the Easter recess, to obtain an act for permanently regulating this fishery. This act, as we are informed, is to be in substance, nearly the same as that of which we have given an abstract, and both modelled (with the exception of the bounties) after a placard or ordinance published at the Hague and Delft, by the states of Holland and West Friesland, in the prime and most successful state of their fisheries, concerning the catching, salting, curing, packing, heightening and laying of herrings &c.

The fine shape, with the peculiar pleasant flavour of the Dutch herrings, owing to their excellent mode of curing, caused them to be more esteemed throughout Europe, than either those of the English or Scotch. However, it is to be hoped since the value of this fishery seems now to be properly appreciated and attended to, that our pickled herrings will be equal, if not superior, to the best of the Dutch, or those of Gotenburg.

The first idea of preserving herrings by pickling, is said to have been suggested about the year 1390, and it was the cause of that fishery becoming afterwards so valuable an article of commerce.

William Bruckfeld, or Beukelings, a native of Bierkliet, a town of Dutch Flanders, who lived about that time, has got the merit of being the first discoverer of
FISHERIES.

this pickling process. We suspect, however, that the fishermen and inhabitants of the town of Yarmouth, in the county of Norfolk, knew the art of preserving and barrelling both red and white herrings before that period. It appears to have been a great and lucrative branch of their trade from the 1300 to 1500, and we see a statute of Edward the Third, in the 31st year of his reign regulating the herring trade and fishery of that place. Bruckfield perhaps improved on the art, but to the merit of the discovery, we do not think him entitled.

According to the time of taking, and mode of curing herrings, they receive various appellations, as, sea-sticks, summers, crux, cowered, and shotten herrings.

When they are intended to be cured with what is called the white pickle, they are cut open, and the guts carefully separated from the milts and roes. Then casting away the guts, and leaving the milts and roes entire, the herrings are first washed well with water, and then put into a brine strong enough to bear an egg, where they are allowed to lie from twelve to sixteen hours; then they are taken out, and after being well drained, the salter begins packing. They first of all strew a quantity of salt, as even as possible, over the bottom of the barrel, and lay a row of herrings over it, sprinkling also some salt over them, and so on, till the whole be completed. The firmer the herrings are packed, they keep the better; and the salter therefore press them down with their hands in the packing, as closely as possible, and before heading the cask, they strew about a platterful of salt over the uppermost row. When the barrel is thus filled, they stop it up very close, lest the air should get in, or the brine flow out, either of which circumstances would be destructive of the fish.

On the coasts of Norfolk and Suffolk, a considerable herring fishery is carried on from September to the end of October. The fish which they generally cure there, are called red herrings. When a boat is loaded, it immediately makes for the shore, and delivers its cargo of herrings to persons who are employed in the guiting and washing of them. After this is done, they are put into a tub with salt, where they remain for twenty-four hours; they are then taken out, and put into wicker baskets, washed, and spitted on small sharp wooden spits, and hung up in chimneys in their herring hangs, where figots are kindled on the floors, for the purpose of drying them. These places will hold ten or twelve thousand at a time. This process of drying is generally ended in about twenty-four hours, and then they are taken down, and put into barrels for keeping. Herrings, when thus cured, have a bright yellow, golden appearance, and from their fine flavour, are in much request, both at home and abroad.

SECT. III. On the Lobster Fishery.

The eastern and rocky shores of Scotland abound with this fish, which is the Cancer Gammarus of Linnaeus; and the great quantities of it sent to the London market, form a very lucrative article of trade. Lobsters are generally found in deep, clear water. They breed in the summer months, and it is said propagate more humano. They are very prolific, and deposit their eggs in the sand. On the 11th of August, Mr. Harmer found in a lobster of thirty-six ounces, the weight of spawn to be 1671 grains, and the number of eggs 21,699. About the 1st of June, they commonly cast their shells, and nature, in a little time, supplies them with a new one. Before this necessary change, the animal swells, and ceases to take its usual food. Many of them die under this painful and violent operation. They only grow in size when their shells are membranous and soft. If any of their claws are torn off by accident, they soon renew them. They remain in season from September to June. The shell is black before it is boiled, but afterwards becomes red. During winter, the cock is supposed to be more delicate eating than the hen lobster. They are taken in what fishermen call pots, which are made either of netting or twiggen work; these, after being baited with garbage, are made fast to a rope, and thrown to the bottom of the sea, where it may be found to be from six to ten feet deep. A buoy is also affixed to them. These pots or baskets resemble a mouse trap, which admits the animal, but prevents his return. On the Yorkshire and Orkney coasts, the fishermen use small nets, with iron hoops, baited with fish guts, and pieces of dried dog fish.

The metropolis makes use of more lobsters than all the kingdom beside. It is chiefly supplied from the British Channel, the coasts of Yorkshire, Northumberland, the Frith of Forth, the eastern shores of Scotland; and Norway, from which last place, a million has been brought in one year. The well smacks, which run from Long Hope in Orkney, afford also a very large supply for the London market. The lobsters which they take or purchase from the Orkney fishermen, after having tied up their large claws, in order to prevent their killing one another, they put in chests, which contain four or five hundred each, and when they collect about 9000, they then stow them aboard the first smack that is to sail for Queenborough, from whence they are taken up in boats to Billingsgate.

By 10 and 11 William III. cap 24, no lobster is to be taken under eight inches in length, from the peak of the nose to the end of the middle fin of the tail; and by 9 Geo. II. cap 33, no lobsters are to be taken on the coasts of Scotland, from the 1st of June to the 1st of September. See our article CHUSTACKOLOGY, Vol. VII. p. 398—400.

SECT. IV. On the Mackerel Fishery.

The mackerel fishery, although a very valuable one for the metropolis, by supplying it plentifully with this fish, is not carried on to much extent in any part of Britain, except in the Channel, and on the coasts of Essex, Suffolk, and Norfolk. The mackerel (Scomber scomber Lin.) is a fish of passage. It remains, during winter, in the deep seas, and does not come on our shores until April or May. It is generally about 17 inches in length, and weighs nearly two pounds. The body is long, round, thick, and fleshy, but very small and slender towards the tail, which is so much forked, that it seems to be almost parted into two distinct fins. Its fecundity is very great; for, according to Hamner's table, he found one in the month of June containing 546,681 eggs. It exhibits a phosphoric light when newly taken. From its shape, it so finely calculated for swimming, it has been proposed as a model for the building of ships. Mackarel are found on the coasts of Normandy and Picardy, and from the Lands End in England to the Red Head in Scotland, gradually decreasing in numbers, from

* The Emperor Charles V. coming to the Low Countries, paid a visit to the town of Bierloft with the Queen of Hungary, to honour the memory and to view the tomb of this supposed fist picker of herrings.
Yarmouth northward. It has been often mentioned, that this fish was in high esteem by the Romans, because it furnished the Garum. We suspect, however, that this is somewhat doubtful, as mackerel are not plentiful in the Mediterranean; and that this precious preparation was rather obtained from the Sebom Thynnus, or tunny, called in Scotland mackerel-stare, fish which abound on the Spanish, French, and Italian shores in that sea.

The eyes of the mackerel, when they first appear on our coasts and during winter, are covered with a kind of white film, they are then nearly blind, this, however, they cast in the beginning of summer. Mackerel are taken either with angle lines or nets. A red rag is an excellent bait for them, and they snap at it freely and greedily, when, according to the seaman's phraseology, it blows fresh, or what Dryden calls a mackerel gale. This fishery continues in the English Channel about four months in the year. Mackerel are chiefly caught for immediate consumption in the home market, an astonishing number being sold fresh every year in London. Some are pickled, and exported in barrels from England; but this trade has of late much declined, as the West India islands are mostly supplied with this article from Nova Scotia, New Brunswick, &c.

Although mackerel are sometimes pretty numerous in the latter part of the season about the Isle of May, and the mouth of the Frith of Forth, very few are brought to the Edinburgh market. See our article England, Vol. IX. p. 13.

Sect. V. On the Oyster Fishery.

The oyster (Ostrea edulis) is a bivalvular testaceous fish, and is to be found in various parts of the kingdom. It is well known, and much esteemed, as a most wholesome and nutritious food. The oysters of Britain, although not the largest, are allowed to be the best in the world. They were so famous for their excellence in the days of the Romans, that according to Juvenal and Pliny, they were carefully conveyed from Sandwich to Rome; indeed, the Rutupina Britana, (waters and shores of Kent,) were noted by these luxurious people, chiefly for their producing this fish. The oysters of Colchester in Essex, and some other parts of England, are perhaps however little inferior to those of Kent. In Scotland, they breed in the creeks and bays of the Orkney and Western Islands; but the most considerable fisheries carried on in this country for oysters, are in the Frith of Forth, near to the Isle of Inchkeith, and Prestonpans, in Musselburgh Bay, which last place is remarkable for oysters of great size and delicate flavour. They get the appellation of Pandoors, from being taken close by the doors of the salt pans. The beds or scalps there, are not at this day nearly so productive as formerly, being over dredged, to answer the great demand for these oysters, not only in the Edinburgh market, but in that of Glasgow.

Oysters generally cast their spat, or spawn, in the month of May; when first shed, it has the appearance of a drop of candle-grease, and adheres to stones, or any other hard substance, which the dredgers technically term culch; — the spat is covered with a shell in two or three days, and, in the course of three years, it becomes of a marketable size. The dredgers make use of a peculiar kind of net, which is very thick, strong, and fastened to three spiles of iron; this they drag along the bottom of the sea, and thus force the oysters into it. In England, many, after being taken in this manner, are carried to different places, and laid in beds, or pits of salt water, in order to feed and fatten. A green colour is often artificially given to them in the salt marshes; but we do not consider it as any improvement, as we think white oysters both look, and taste, better than those that are green. The sea star (Asterias glacialis) is a most destructive animal in a bed of oysters, because it clasps its rays around the shell, and perseveres till it sucks the animal out. The fishing for oysters is permitted from the first of September to the last day of April inclusive; or oysters are in season, according to vulgar observation, in all those months which have the letter r in their name. See our article Conchology, Vol. VII. p. 98, genus Ostrea; and our article England, Vol. IX. p. 14.

Sect. VI. On the Pilchard Fishery.

The pilchard forms a distinct species in the genus Clupea, (C. pilchardus.) There are several naturalists, who insist that it is only a variety of the herring; however, we have various reasons for thinking otherwise. It is less and thicker than the herring, the nose turns up, the under jaw is shorter than the upper, the dorsal fin is placed exactly in the centre of gravity, for if you take a pilchard by the back it will hang even, which a herring will not do; the scales are firm, and adhere very closely, whereas those of the herring come off with the smallest touch.

The pilchard is a fish of passage, swims in shoals, and its arrival on the coasts of Bretagne, Cornwall, and Devonshire, is indicated by similar signs with the approach of the herring towards Shetland. The season of this fishery is from June to September, although they are sometimes caught about Christmas.

On the jutting cliffs, upon the coasts of Devonshire and Cornwall, men are set, whom they call huercs, to watch the coming of the pilchards; the purple colour of the water in the day, and its shining appearance in the night, give certain indication of their approach. Then the huercs, according to settled and regulated signs, direct the boats and vessels how to manage their seins, and when their commands are properly given and obeyed, they have been known to take, in their nets, 100,000 pilchards at a draught. It is a common saying of the Cornish fishermen, when talking of the pilchard, that it is the least fish in size, most in number, and greatest in gain, of any they take out of the sea.

In Scotland there are no established fisheries for pilchards; they sometimes appear among the herring shoals, especially in the Frith of Forth, where they are accounted a very insipid fish. See our article England, Vol. IX. p. 13.

Sect. VII. On the Salmon Fishery.

In order to understand our account of this fishery, it will be requisite to have a slight knowledge of the natural history of the salmon, (Salmo salar,) but as we have already given this in our article Angling, we shall not resume this subject at present.

It is scarcely in the power of human skill to reduce the numbers, or extinguish the race of such fish as make the sea their only element. But this is not the case with fresh water, or rather fluvial fishes, which being confined in narrow limits, are consequently within the easy reach of the avaricious contrivances of men, and
FISHERIES.

that too without their encountering either the toils or dangers attendant upon the fisheries of the seas. Indeed, had it not been for the restraining statutes respecting the manner and times of catching them, the breed of salmon would, in all probability, have been long ere now extirpated.

Several of the genus *Salmo* are anadromous fishes, or such as alternately inhabit fresh and salt waters; all of them, however, spawning in the heads of rivers, or in brooks connected with them. After performing this function, they become lank and sickly. In this situation they make for the sea, no doubt to recover from their stunted state. After remaining there for a few weeks, an irresistible impulse of nature hurries them again to their native streams. To accomplish this object, they set all kinds of obstacles at defiance, and would rather perish in the attempt than deviate from their course. They never spawn until they reach these shoals, and if obstructed or retarded in their ascent, they are often forced to drop their roes in the lower parts of rivers, but which, in that case, are never known to be either impregnated or covered by the milt. It has been remarked that their periodical migrations are in part prompted by another circumstance. During their residence in the rivers, they are infested by parasitical insects, which are killed by the salt water; but in the sea they are soon attacked by the *lernica*, which perishes in fresh water.

The importance of the salmon fishery to Scotland, induced the legislature, at an early period of our history, to enact various statutes, for the preservation and multiplication of the breed, and for prohibiting all kinds of apparatus in their capture, which might tend to a diminution of their numbers. Such is the spirit of our laws respecting this valuable fishery; but within these thirty or forty years, the existing laws have not been duly enforced, and, of course, a great and sensible decrease has taken place in all the waters of Scotland; and, indeed, in many rivers in which they used formerly to abound, scarcely one is now to be seen, as for example, in the Almond and Erich in Perthshire, both branches of the Tay. In the upper parts of the Tweed, from Kelso to Drumelzier, there were formerly several established salmon fisheries, but these are now entirely relinquished, from the small number of fish which ascend to that part of the river. The cause of this scarcity is attributed to the modes of fishing with stage, toot nets, &c. at or near to the mouth of that river.

Although we only mention these circumstances as coming within our immediate knowledge, we believe that the same decrease may be observed in the interior parts, as also in the tributary streams of all the principal rivers in Scotland.

It has been contended by many of the lower proprietors upon our rivers and estuaries, that stake nets, and other such sweeping devices, do not lessen the breed of salmon; that the Scotch acts of parliament are now in desuetude; and even if they were still in force, that they do not apply nor allude to such apparatus, nor to the passage of salmon upwards, but only to the preservation of the breeders in close or fense time, and to the smouts, fry, or salmon seuse.

The most material object, undoubtedly, in the propagation and preservation of the salmon species, is to afford them a safe passage to their parent stream, that bed which nature has pointed out to them as the safest and best, in which they can lay the seeds of their future offspring. We have, indeed, already noticed, that, if they are prevented from reaching this spot, the spawn is rendered unprofitable, by their dropping it without any further care or concern.

That our statutes have the protection of this passage upwards in view, we apprehend can hardly be questioned. The prohibitory clauses respecting the use of certain nets, devices, &c. the observance of close time, of the Saturday’s *slap*, or the mid stream, &c. all corroborate this supposition. Indeed, amidst the various laws enacted by the Scottish parliament for the preservation of the breed of this fish, it would be an absurdity to imagine, that the most effectual safeguard for their propagation should be neglected; that is, a complete protection in their ascent to the spawning grounds.

As the law at present stands, we consider all modes in the capture of this fish to be illegal, unless by angling, by the net and cobbie, or by the common seine, of moderate and fixed dimensions. But to prevent all disputes, and to meet the exigency of the times with regard to the preservation of salmon, we apprehend legislative interference would have at present an excellent effect, not only in settling such means as may render this fishery permanent and productive, but would put an end to the many litigations that take place between the upper and lower proprietors of our salmon rivers.

Notwithstanding the ancient, and seemingly correct laws for the conservancy of the Thames, yet trespasses increased so much, and the offences in fishing became so intricate and destructive, that the city of London found it necessary and expedient, in the 30th year of the reign of George II. to obtain another act of parliament, for the better regulating the fisheries in that river, and in the waters of Medway. In pursuance of this statute, the lord mayor (Clark) in 1785 published a set of rules, orders, and ordinances, containing penalties for a breach of the same; and annexed to this publication, are notes by the Lords Mansfield and Loughborough approving thereof.

From these ordinances, now acted upon in the court for the conservation of the river Thames, we select the following articles, being, as we think, not only well adapted to, but somewhat explanatory of, the spirit of both the Scottish and English laws with regard to our salmon fisheries.

"*Imprints*. That all unlawful nets and engines, and other abuses, offered to the prejudice and destruction of the fishery, may be discovered. That no person shall stall the tide of flood.

2. *Item*, That no person shall lie or bend over any net whatsoever during the time of flood, whereby any kind of fish may be hindered or kept back from swimming upwards, for the benefit and profit of such fishermen, as well above London Bridge, in the west part of the said river, under penalty of forfeiting and paying five pounds for every such offence.

3. *Item*, That no person shall shoot, or place any draw net, cod net, or other net or engine in the said river Thames, to catch salmon with, or shall use any net or device to catch salmon in the said river of Thames, except only with a net of full six inches in the mesh, and that no person shall wilfully do, or commit, or cause to be done or committed, any act whatsoever in the said

* The Irish complain much of the decrease of salmon in their rivers; and Wakefield, in his Statistical Account of Ireland, mentioning the modes of capture in some of their fisheries, observes, that "flood weirs are more injurious than cobbie weirs, as they catch the fish in their ascent." Vol. ii. p. 93.
river Thames, whereby any spawn, or small fry of salmon, shall be taken, killed, or destroyed, or whereby any salmon shall be hindered from passing or going up the said river Thames to spawn, upon the penalty of forfeiting five pounds for every such offence.

4. Item, That no person, between the 10th day of September and the 23rd day of January in every year, shall fish in the said river of Thames, or waters of Medway, for salmon, with any net or nets, engine or device; or within that time take, kill, or destroy in the said river or waters salmon of any kind, or offer them for sale, under the penalty of five pounds for every such offence.

5. Item, That no person shall fish with any net, or lay or haul any mesh, engine, or device whatsoever in the said river or waters, from sun-setting on Saturday night, until sun-rising on Monday morning, at any time of the year, under a penalty of forty shillings for every such offence.

18. Item, That no person shall bind any net by anchors, or otherwise thwart the channel, or draw any other net, engine, or device, into, upon, or near it; or use any net with any false or double bottom, cod, or pouch, under the penalty of five pounds for every such offence.

20. Item, That no person shall fish, or attempt to take fish, with any sort of net in the night-time, or before sun-rising, or after sun-setting, at any time of the year, in the said river Thames, between Richmond bridge and the city of London's mark stone above Stainesbridge, under a penalty of five pounds for every such offence.

24. Item, That no salmon caught in the Thames or Medway, shall be exposed to sale of less weight than six pounds, under a penalty of five pounds.

47. Item, That no person shall put down at the mouth of any creek, river, or back water, growing out of the Thames or Medway, or communicating therewith, or running into the said river or waters, or at any mill or sluice within the said jurisdiction, any frame net, hoop net, or purse net, or any weir or device whatsoever, to stop, catch, or hinder the fish, or spawn, or fry of fish, from coming into the said river or waters, under a penalty of five pounds for every such offence.

55. Item, That no person shall have, or occupy, or fix up, drive down, or place, or cause to be fixed up, drove down, or placed in any part of the said river Thames or waters of Medway, any wear, stalk, stop, hatch, weir, reed, or other device to take fish in, within the jurisdiction aforesaid, under a penalty of five pounds for every offence, in breach of any part of this order.

Such are the ordinances respecting the salmon fishery observed in the court, held before the lord mayor for the conservation of the Thames. It is the duty of the water bailiff, or his assistants, to give notice of trespasses, and the persons committing them never escape unpunished. The above articles are not enumerated in order, as the intervening ones apply to other fish than the salmon.

It is much to be wished, that similar regulations were enacted for the conservation of our rivers in Scotland. That salmon have of late years greatly decreased in numbers, and are still fast decreasing, we believe will not be disputed by any one, and it can hardly be expected that this fishery will flourish, until all devices and modes of fishing which prevent them from easily reaching their spawning grounds be effectually removed. For this purpose, all stake, took, and other stationary nets, should be prohibited and declared illegal. A purchase of all cruives should be made from those persons, who by particular grants now inherit or possess them. Rights of property, held to be inconsistent with the common weal, have, in the cases of tithes and thirlage in Scotland, already been the subject of legislative provisions, the object of which was to remove the incumbence on the general prosperity, without injury to the owner. Perhaps the justice and expediency of this interposition are still more obvious with regard to rights of fishing, by modes injurious to the fishery at large; for each proprietor of such rights has a direct interest in the benefit that might result from a judicial sale of these, because, after obtaining the value of his peculiar privilege, he would share in the increase of the general fishery.

If any alteration should take place in the laws regarding the capture of salmon, fence time, in Scotland termed close time, should be prolonged, and extended indiscriminately to all the rivers in Britain; that is, beginning upon the first of August, and to continue until the end of January, or from Lammas till Candlemas day. This would prevent any interruption to salmon in the month of August, when heavy with milts and roes in making up to the head waters for the purpose of spawning. It would also save many shotten fish from being taken in December and January, when on their passage to the sea.

There seems to be no general law respecting the fence months in the rivers of Scotland, all the fisheries commonly commencing and ending at different times, according to various acts of parliament. In the Forth and Tay, the fisheries begin on the 11th of December, and terminate on the 26th of August. In the Tweed, they fish from the 11th of January to the 10th of October. In the north Esk in Kincardineshire, from Candlemas to Michaelmas. In the Dee and Don, from the 11th of December to the 19th of September. In the Spey, from the 30th of November to the 26th of August.

We cannot accurately ascertain the periods of fishing in our other principal salmon rivers, which, beside the many tributary streams, are, the Clyde, Luce, South Esk in Forfarshire, Doweran, Ness, Bently, Thurso, and the Annan, with others running into the Solway Frith.

The chief rivers in England frequented by this fish, are, the Thames, Medway, Severn, Mersey, Trent, Dee, Ex, Usk, Wye, Loo, Weever, and Tyne.
